Figure 4-17 GR Completion

After the GR Restarter synchronizes all required data, all devices enter IS-IS interaction state. The GR Restarter's routing table is updated to the forwarding table and invalid entries are cleared. Because the GR Restarter is completely restored to the pre-restart state under stable network conditions, its routing table and forwarding table remain unchanged before and after GR.

Notes

- IS-IS GR is implemented based on RFC5306: Restart Signaling for IS-IS.

✓ All products support the IS-IS GR Helper capability.

Configuration Steps

↘ Enabling the IS-IS GR Restart Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Configuring the Maximum GR Time

- Perform this configuration based on requirements.
- Run the **graceful-restart grace-period** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Enabling the IS-IS GR Help Capability

- Perform this configuration based on requirements.
- Run the **graceful-restart helper** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the routing table and forwarding table remain unchanged before and after GR.

Related Commands

▾ Enabling the IS-IS GR Restart Capability

Command	graceful-restart
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to enable the IS-IS GR Restart capability. As long as the network conditions remain unchanged, IS-IS can be restarted and restored to the pre-restart state without impact on data forwarding.

▾ Configuring the Maximum GR Time

Command	graceful-restart grace-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the GR time. The value range is 1s to 65,535s. The default value is 300s.
Command Mode	IS-IS routing process configuration mode
Usage Guide	N/A

▾ Enabling the IS-IS GR Help Capability

Command	graceful-restart helper disable
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use the graceful-restart helper disable command to disable the IS-IS GR Help capability. The command enables IS-IS to ignore the GR request sent by the device to be restarted.

Configuration Example

▾ Configuring IS-IS GR

Configuration Requirements	<p>Two high-end devices should have the IS-IS GR Restart capability and are equipped with master/slave management boards for redundant backup at the control plane. IS-IS neighbor relationships are established between devices. The system software of all devices supports the IS-IS GR Help capability.</p> <p>The following configuration requirements exist: Enable the IS-IS GR Restart capability with proper GR Time setting on device 1 and device 2 to realize uninterrupted forwarding and improve core device reliability. Disable the IS-IS GR Help capability on the device to exclude it from the Help process. By default, other device supports the IS-IS GR Help capability and require no additional configuration.</p>
-----------------------------------	---

4.4.8 Configuring BFD Support for IS-IS

Configuration Effect

- IS-IS dynamically discovers neighbors through Hello packets. After IS-IS enables the BFD function, a BFD session will be set up with the neighbor in Up state. The BFD mechanism is used to detect the neighbor state. Once a neighbor

failure is detected through BFD, IS-IS performs network convergence immediately. The convergence time can be reduced from 30s to less than 1s. By default, IS-IS Hello packets are sent at an interval of 10s in a P2P network, and the time required to detect a neighbor failure is three times the packet interval, that is 30s.

Notes

- You must set BFD session parameters before you enable BFD support for IS-IS.
- When you run the **bfd up-dampening** command on an interface with BFD support for IS-IS, you need to run the **bfd all-interfaces** command with the *[anti-congestion]* option selected.
- When you run the **bfd all-interfaces** command with the *[anti-congestion]* option selected, run the **bfd up-dampening** command on the interface.
- IP routing may cause a neighbor's interface for BFD session setup to be inconsistent with the interface for outgoing BFD packets. If this happens, the BFD session cannot be set up.
- If a neighbor's interface for BFD session setup is inconsistent with the interface for outgoing BFD packets, the BFD session cannot be set up.

Configuration Steps

↘ Enabling BFD Support for IS-IS on All Interfaces

- Perform this configuration based on requirements.
- Run the **bfd ll-interfaces** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Enabling BFD Support for IS-IS on the Current Interface

- Perform this configuration based on requirements.
- Run the **isis bfd** command in interface configuration mode on the desired device, unless otherwise specified.

Verification

- Build a topology with two parallel lines. Typically, IS-IS selects one line as the master line and the other as the backup line. Enable BFD on the master line.
- Make the master line fail. Check whether IS-IS performs route convergence based on the BFD monitoring state and starts the backup line.

Related Commands

↘ Enabling BFD Support for IS-IS on the Current Interface

Command	bfd all-interfaces <i>[anti-congestion]</i>
Parameter Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command	IS-IS routing process configuration mode

Mode	
Usage Guide	<p>You can enable or disable BFD on an IS-IS interface by using any of the following two methods:</p> <p>Method 1: Run the bfd all-interfaces command in IS-IS routing process configuration mode to enable BFD on all IS-IS interfaces, and then run the no bfd all-interfaces command to disable BFD on all IS-IS interfaces.</p> <p>Method 2: Run the isis bfd [disable] command in interface configuration mode to enable BFD on the specified IS-IS interface, and then run the isis bfd disable command to disable BFD on the interface.</p>

↳ Enabling BFD Support for IS-IS on the Current Interface

Command	isis bfd [disable anti-congestion]
Parameter	<i>disable</i> : Disables BFD support for IS-IS on the current interface.
Description	<i>anti-congestion</i> : Indicates the IS-IS BFD anti-congestion option.
Command Mode	Interface configuration mode
Usage Guide	<p>You can enable or disable BFD on an IS-IS interface by using any of the following two methods:</p> <p>Method 1: Run the [no] bfd all-interfaces [anti-congestion] command in IS-IS routing process configuration mode to enable or disable BFD on all IS-IS interfaces.</p> <p>Method 2: Run the isis bfd [disable anti-congestion] command in interface configuration mode to enable or disable BFD on the specified interface.</p> <p>Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With the introduction of new techniques such as the Multi-Service Transport Platform (MSTP), link congestion tends to occur during peak hours of data communication. BFD quickly detects the link exception and instructs IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping.</p> <p>The anti-congestion option is used to avoid routing flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping.</p> <p>When you run the bfd all-interfaces [anti-congestion] command, run the bfd up-dampening command on the interface. The two commands must be used together. If you run only one command, the route flap dampening feature may not take effect or other network exceptions may occur.</p>

Configuration Example

➤ **Enabling BFD Support for IS-IS on the Current Interface**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Set BFD session parameters. (Omitted) ● Enable BFD support for IS-IS on the current interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis bfd</pre>
Verification	<p>Enable S1 (192.168.1.10) and S2 (192.168.2.10) to send packets to G1 (229.1.1.1) and G2 (229.1.2.1). Add User to the G1 and G2 groups.</p> <ul style="list-style-type: none"> ● Check the multicast packet that User receives. User should only receive the (S1, G1) packet. ● Check that the PIM-SM routing table does not have the (S1, G2), (S2, G1), and (S2, G2) entries.
	<pre>A# show bfd neighbors detail</pre>

Common Errors

- BFD support for IS-IS is not enabled on neighbors.

4.4.9 Setting the IS-IS Overload Bit

Configuration Effect

The overload bit is used in the following three situations:

- Device overload

The local IS-IS node has overload issues, such as insufficient memory or full CPU load; as a result, its routing table has incomplete routes or does not have resource forwarding data. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. When the local IS-IS node is restored, manually cancel the command configuration; otherwise, the node is always in overload state.

- Instantaneous black hole

In the scenario described by RFC3277, the IS-IS convergence speed is faster than the BGP speed; as a result, after an IS-IS node is restarted, a route may be instantaneously unreachable, which is called an instantaneous black hole. You can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device until the specified time has elapsed.

To set the overload bit, run the **set-overload-bit** command with the **on-startup** keyword. The overload bit can be configured or canceled automatically by the IS-IS node based on the configuration. If the **on-startup** keyword is selected, the IS-IS node

automatically enters instantaneous black hole state after restart. When a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit to notify the neighbor that the local node enters instantaneous black hole (or overload) state and instruct the neighbor not to use the local node as a forwarding device. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify the neighbor that the local node has exited instantaneous black hole (or overload) state and can work as a forwarding device.

- Disabling real data forwarding on the local IS-IS node

If you only need to connect the local IS-IS node to a production network for testing or to meet other functional requirements, but does not require the node to forward real data in the network, you can set the overload bit in an LSP to instruct the neighbor not to use the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or canceled manually. You can set the **suppress** keyword based on requirements to limit the routing information carried in an LSP in case of overload. For example, internal and external routes can be suppressed, and only the local direct route is advertised.

Notes

- At the same Level, the configuration with the **on-startup** keyword is mutually exclusive with the configuration without the **on-startup** keyword.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **set-overload-bit** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Capture packets and check that the neighbor does not forward LSPs from the local node.

Related Commands

Command	set-overload-bit [on-startup seconds] [suppress { [interlevel] [external] }] [level-1 level-2]
Parameter Description	<p>on-startup seconds: Indicates the duration when an IS-IS node remains in overload state after restart. The value range is 5s to 86,400s.</p> <p>suppress: Indicates not to advertise internal routes (intra-area and inter-area routes) or external routes to neighbors when the IS-IS node is in overload state.</p> <p>interlevel: Indicates not to advertise intra-area and inter-area routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword.</p> <p>external: Indicates not to advertise external routes to neighbors when the IS-IS node is in overload state. It is used with the suppress keyword.</p> <p>level-1: Sends LSPs with the overload bit only to Level-1 neighbors.</p> <p>level-2: Sends LSPs with the overload bit only to Level-2 neighbors.</p>
Command	IS-IS routing process configuration mode

Mode	
Usage Guide	<p>Use this command to force an IS-IS node to set the overload bit in a non-virtual LSP to instruct its IS-IS neighbors not to use the local node as a forwarding device.</p> <p>If you select the on-startup keyword, the IS-IS node automatically enters overload state after restart.</p> <p>If you do not select the on-startup keyword, the IS-IS node enters overload state immediately after restart.</p>

Configuration Example

Configuring the Overload Bit in Case of an Instantaneous Black Hole

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Verify that the IS-IS node enters instantaneous black hole state immediately after restart and remains in this state until the specified time (300s) has elapsed, and the IS-IS node only advertises local direct links to its neighbors during the specified time.
	<pre>A(config)# router isis A(config-router)#set-overload-bit on-startup 300 suppress interlevel external</pre>
Verification	<p>Capture packets to check LSPs.</p> <ul style="list-style-type: none"> Verify that the IS-IS node automatically enters instantaneous black hole state after restart. Once a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit. After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify its neighbors that the local node has exited instantaneous black hole (or overload) state.
	<pre>A# show isis neighbors</pre>

Disabling Real Data Forwarding on the Local IS-IS Node

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Connect the local IS-IS node as a test device to a production network. The node is not required to forward real data in the network to avoid impact on production.
	<pre>A(config)# router isis A(config-router)#set-overload-bit suppress interlevel external</pre>
Verification	<p>Capture packets to check LSPs. Verify that the LSPs carry the overload bit and only advertise local direct routes.</p>
	<pre>A# show isis neighbors</pre>

4.4.10 Configuring IS-IS VRF

Configuration Effect

- Each VRF table can be seen as a virtual device or a dedicated PE device.
- The virtual device contains the following elements: an independent routing table, as well as an independent address space; a set of interfaces that belong to the VRF table; a set of routing protocols applicable only to the VRF table.
- Each device can maintain one or more VRF tables and a public-network routing table (also called a global routing table). Multiple VRF instances are separated from each other.

Notes

- Note the following constraints or conventions when you bind IS-IS instances and VRF tables:
- The IS-IS instances bound with the same VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip router isis [tag]** interface configuration and the redistribution configuration in routing process configuration mode will be deleted.

Configuration Steps

- Perform this configuration based on requirements.
- Run the **vrf** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.

Related Commands

📌 Configuring IS-IS VRF

Command	vrf vrf-name
Parameter Description	<i>vrf-name</i> : Indicates the name of an existing VRF table.
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Before you bind an IS-IS instance to a VRF table, ensure that the VRF table has been configured. If you need to establish an IS-ISv6 neighbor relationship, enable IPv6 and ensure that the table to be bound is a multiprotocol VRF table.</p> <p>Note the following constraints or conventions when you bind IS-IS instances and VRF tables:</p> <ul style="list-style-type: none"> ● The IS-IS instances bound with the same non-default VRF table must be configured with different system IDs. The IS-IS instances bound with different VRF tables can be configured with the same

	<p>system ID.</p> <ul style="list-style-type: none"> ● One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances. ● When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the ip (or ipv6) router isis [tag] interface configuration and the redistribution configuration in routing process configuration mode will be deleted.
--	---

Configuration Example

Configuring IS-IS VRF

Configuration Steps	<ul style="list-style-type: none"> ● Bind an IS-IS instance to a VRF table. ● Add interfaces to the VRF table and IS-IS instance. (Omitted)
	<pre>A(config)#vrf definition vrf_1 A(config-vrf)#address-family ipv4 A(config-vrf-af)#exit-address-family A(config)# router isis A(config-router)# vrf vrf_1</pre>
Verification	Check whether the local device establishes neighbor relationships with other devices specified in the VRF table.
	<pre>A# show isis neighbors</pre>

Common Errors

- Interfaces are not added to the VRF table.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level-1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

4.4.11 Configuring IS-IS MTR

Configuration Effect

- If the **multi-topology** command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the **multi-topology** command is executed without the **transition** parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the **multi-topology** command is executed with the **transition** parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.

Notes

Note the following constraints or conventions when you configure the IS-IS MTR feature:

- Set **metric-style** to **Wide** or **Transition** before you run the **multi-topology** command.
- The MTR feature will be disabled if **metric-style** is set to **Narrow** or only one Level is configured to support the Wide or Transition mode.

Configuration Steps

- Perform this configuration based on requirements.
- Configure the MTR feature in IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

Verification

- Check whether the local device establishes neighbor relationships with other devices.

Related Commands

↳ Configuring IS-IS MTR

Command	multi-topology [<i>transition</i>]
Parameter Description	<i>transition</i> : Configures the MTT mode, which supports smooth migration from an IPv4-IPv6 hybrid topology to separate IPv4 and IPv6 topologies.
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	<p>If the multi-topology command is not executed, IPv4 and IPv6 share one IS-IS physical topology, also called the default topology. If the multi-topology command is executed without the transition parameter, routing devices run in MT mode. IS-ISv4 runs in the default topology, and IS-ISv6 runs in the IPv6 unicast topology. If the multi-topology command is executed with the transition parameter, routing devices run in MTT mode. IS-ISv6 runs in the default topology and IPv6 unicast topology. The three configurations are mutually exclusive. The routing devices in MTT mode can transfer the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.</p> <p>Set metric-style to Wide or Transition before you run the command. The MTR feature will be disabled if metric-style is set to Narrow or only one Level is configured to support the Wide or Transition mode.</p>

Configuration Example

➤ **Configuring IS-IS MTR**

<p>Configuration Requirements</p>	<p>The typical application scenario of MTR is to retain devices that only support IPv4 services in a network where IPv6 service extension will be performed.</p> <p>In Figure 4-19, Router 2 only supports the IPv4 protocol stack but does not support the MTR feature; therefore, it can only run IPv4 services. The network capacity needs to be scaled to support IPv6 services in order to meet service extension requirements. (Router 1, Router 3, and Router 4 that support the MTR feature will be added.) The device (Router 2) that supports only one protocol stack must be replaced to maintain the stability of the network running IPv4 and IPv6 dual protocol stacks; otherwise, IPv6 routing black holes may occur.</p> <p>If you need to retain Router 2, you can configure the MTR feature on Router 1, Router 3, and Router 4. The MTR feature enables Router 2 to continue to run IPv4 services without interference on the IPv4 and IPv6 services on Router 1, Router 3, and Router 4. The MTR feature improves networking flexibility, indirectly prolongs the service life of old devices, and meets service extension requirements while maximizing the values of old devices.</p> <p>The configuration requirements are as follows:</p> <ul style="list-style-type: none"> ● Retain Router 2, which only supports IPv4 services. ● Add devices that support IPv4 and IPv6 dual topologies, and separate IPv4 route calculation and IPv6 route calculation based on different topologies.
<p>Figure 4-19 IS-IS MTR Topology</p>

```

Common Errors

- **metric-style** is not set to **Wide** or **Transition**.
- The protocol types used by two neighbors do not match; therefore, a neighbor relationship cannot be established.
- The IP addresses of the interfaces connected between neighbors are not in the same network segment.
- The **ip router isis** command is not executed on interfaces.
- No NET address is configured, or different NET addresses exist at Level 1.
- **max-area-addresses** is configured differently on both sides.
- **metric-style** is configured differently on both sides.
- The interface Levels on both sides are different. One side is Level-1, whereas the other side is Level-2.
- One side is configured with the P2P mode, whereas the other side is configured with the broadcast mode.
- One side is enabled with authentication, whereas the other side is not.

4.4.12 Configuring SNMP for IS-IS

Configuration Effect

- By default, the SNMP software can perform the MIB operation on the first IS-IS instance. To perform the MIB operation on other instances, you need to manually specify these instances.

Notes

- By default, the SNMP software can perform the MIB operation on the first displayed IS-IS instance.

Configuration Steps

↘ Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

- Perform this configuration based on requirements.
- Run the **enable mib-binding** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

↘ Enabling IS-IS Trap Globally

- Perform this configuration based on requirements.
- Run the **snmp-server enable traps isis** command in global configuration mode on the desired device, unless otherwise specified.

↘ Configuring an SNMP Host Globally

- Perform this configuration based on requirements.
- Run the **snmp-server host** command in global configuration mode on the desired device, unless otherwise specified.

↘ Allowing the Sending of all IS-IS Trap Messages to the SNMP Host

- Perform this configuration based on requirements.
- Run the **enable traps all** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- Use the MIB tool to read and write IS-IS settings.

Related Commands

↘ Binding the Instances on Which the IS-IS MIB Operation Will Be Performed

Command	enable mib-binding
Parameter	N/A
Description	
Command	IS-IS routing process configuration mode

Mode	
Usage Guide	The latest standards stipulate that the MIB operation can be performed on a single instance. By default, the MIB operation is performed on the first displayed IS-IS instance. Because multiple IS-IS instances can be configured, the administrator can use this command to specify the instances on which the MIB operation will be performed.

▾ Enabling IS-IS Trap Globally

Command	snmp-server enable traps [<i>isis</i>]
Parameter Description	<i>isis</i> : Enables IS-IS event trap.
Command Mode	Global configuration mode
Usage Guide	This command must be used with the snmp-server host command in global configuration mode so that trap messages can be sent.

▾ Configuring an SNMP Host Globally

Command	snmp-server host { <i>host-addr</i> ipv6 <i>ipv6-addr</i> } [vrf <i>vrfname</i>] [traps] [version { 1 2c 3 { auth noauth priv }] <i>community-string</i> [udp-port <i>port-num</i>] [<i>notification-type</i>]
Parameter Description	<p><i>host-addr</i>: Indicates the address of the SNMP host.</p> <p><i>ipv6-addr</i>: Indicates the IPv6 address of the SNMP host.</p> <p><i>vrfname</i>: Indicates the name of a VRF table.</p> <p>version: Indicates the SNMP version, which can be set to V1, V2C, or V3</p> <p>auth noauth priv: Indicates the security level of V3 users.</p> <p><i>community-string</i>: Indicates the community string or user name (V3 version).</p> <p><i>port-num</i>: Indicates the port number of the SNMP host.</p> <p><i>notification-type</i>: Indicates the type of trap messages that are actively sent, for example, snmp.</p>
Command Mode	Global configuration mode
Usage Guide	This command is used with the snmp-server enable traps command to actively send trap messages to a Network Management System (NMS). You can configure different SNMP hosts to receive trap messages. A host supports different trap types, ports, and VRF tables. For the same host (with the same port configuration and VRF configuration), the last configuration is combined with the previous configurations. That is, to send different trap messages to the same host, configure a type of trap messages each time. These configurations are finally combined.

▾ Allowing the Sending of Trap Messages

Command	enable traps { all <i>traps set</i> }
Parameter Description	<p>all: Indicates all trap messages.</p> <p><i>traps set</i>: Indicates a trap message type in any set.</p>

Command Mode	IS-IS routing process configuration mode
Usage Guide	IS-IS packets are classified into 18 types of trap messages, which are grouped into several sets, with each set containing several trap message types. To enable the sending of IS-IS trap messages, run the snmp-server enable traps isis command in global configuration mode and specify the recipient host and the type of trap messages that can be sent.

Configuration Example

Configuring IS-IS SNMP

Configuration Steps	<ul style="list-style-type: none"> ● Bind the instances on which the IS-IS MIB operation will be performed. ● Complete trap message-related settings.
	<pre>A(config)# router isis A(config-router)# enable mib-binding A# configure terminal A(config)#snmp-server enable traps isis A(config)#snmp-server host 10.1.1.1 traps version 2c public A(config)#router isis A(config-router)# enable traps all</pre>
Verification	Run the MIB tool to read and write IS-IS settings.
	<pre>A# show running-config</pre>

4.4.13 Configuring Other IS-IS Parameters

Configuration Effect

- **maximum-paths:** Configures the maximum number of IS-IS equal-cost paths to be installed to a routing table.
- **lsp-length receive:** Configures the maximum length allowed for received LSPs.
- **lsp-length originate:** Configures the maximum length allowed for sent LSPs.
- **passive-interface:** Prevents passive interfaces from receiving and sending IS-IS packets. That is, IS-IS neighbor relationships will not be established on passive interfaces. The IP addresses of passive interfaces are flooded through other interfaces.
- **isis metric:** Stores the metric, which is used in SPF calculation, in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation.

- **isis priority:** In a broadcast network, IS-IS needs to elect a DIS among all devices. The DIS will generate a pseudonode and related LSPs. The device with the highest priority is elected as the DIS. You can configure different priorities for different Levels.
- **default-information originate:** Generates a Level-2 default route, which will be advertised through LSPs.
- **spf-interval:** Configures the exponential backoff algorithm of SPF.
- **summary-address** and **summary-prefix:** Creates a summary route to represent a group of routes in a routing table. A summary route can include multiple routes of the specified Level. The interface metric of the summary route follows the smallest interface metric among all routes.
- **log-adjacency-changes:** Enables neighbor relationship event output to log IS-IS neighbor relationship changes.
- **redistribute:** Redistributes other routes to IS-IS; redistributes Level-1 routes to Level-2; redistributes Level-2 routes to Level-1.

Configuration Steps

▾ Configuring the Maximum Number of Equal-Cost Paths

- Perform this configuration based on requirements.
- Run the **maximum-paths** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Maximum Length Allowed for Received LSPs

- Perform this configuration based on requirements.
- Run the **isp-length receive** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Maximum Length Allowed for Sent LSPs

- Perform this configuration based on requirements.
- Run the **isp-length originate** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring a Passive Interface

- Perform this configuration based on requirements.
- Run the **passive-interface** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ Configuring the IS-IS Interface Metric

- Perform this configuration based on requirements.
- Run the **isis metric** command in interface configuration mode on the desired device, unless otherwise specified.

▾ Configuring the Priority of the DIS

- Perform this configuration based on requirements.
- Run the **isis priority** command in interface configuration mode on the desired device, unless otherwise specified.

▾ **Configuring the SPF Calculation Cycle**

- Perform this configuration based on requirements.
- Run the **spf-interval** command in interface configuration mode on the desired device, unless otherwise specified.

▾ **Generating a Default Route**

- Perform this configuration based on requirements.
- Run the **default-information originate** command in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

▾ **Configure a Summary Route**

- Perform this configuration based on requirements.
- Run the **summary-address** and **summary-prefix** commands in IS-IS routing process configuration mode or IS-IS address-family ipv6 configuration mode on the desired device, unless otherwise specified.

▾ **Enabling Neighbor Relationship Event Output**

- Perform this configuration based on requirements.
- Run the **log-adjacency-changes** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

▾ **Configuring Route Redistribution**

- Perform this configuration based on requirements.
- Run the **redistribute** command in IS-IS routing process configuration mode on the desired device, unless otherwise specified.

Verification

- **maximum-paths:** Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
- **lsp-length receive:** Capture packets to check the length of LSPs.
- **lsp-length originate:** Capture packets to check the length of LSPs.
- **passive-interface:** Capture packets to check whether the interface receives and sends IS-IS packets.
- **isis metric:** Check the database details of IS-IS.
- **isis priority:** Check whether the device with the changed priority setting is elected as the DIS.
- **default-information originate:** Check whether a default route is generated.
- **spf-interval:** Check whether the SPF calculation cycle works.

- **summary-address and summary-prefix:** Capture packets to check whether the summary route instead of detailed routes is advertised through LSPs.
- **log-adjacency-changes:** Change the neighbor state and verify that the change is recorded when debugging is disabled.
- **redistribute:** Check IS-IS routing entries.

Related Commands

▾ Configuring the Maximum Number of Equal-Cost Paths

Command	maximum-paths <i>maximum</i>
Parameter Description	<i>maximum</i> : Indicates the maximum number of IS-IS equal-cost routes to be installed to a routing table. The value range is 1 to 32.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	This command is used by IS-IS to control the number of IS-IS equal-cost paths to be installed to a routing table. The routing table also has a command used to control the number of equal-cost paths. The number of effective equal-cost paths is determined by either of the two command values, whichever is smaller.

▾ Configuring the Maximum Length Allowed for Received LSPs

Command	lsp-length receive <i>size</i>
Parameter Description	<i>size</i> : Indicates the maximum length allowed for received LSPs. According to RFC, the value range is 1,492 to 16,000, in the unit of bytes.
Command Mode	IS-IS routing process configuration mode
Usage Guide	Use this command to control the maximum length allowed for LSPs received by the local device. Intermediate nodes with sufficient memory are required to receive LSPs whose maximum length is equal to the interface MTU in order to avoid a route convergence failure. From this perspective, the command is meaningless. The maximum length allowed for received LSPs cannot be smaller than that allowed for sent LSPs; otherwise, the former will be automatically adjusted to be equal to the latter.

▾ Configuring the Maximum Length Allowed for Sent LSPs

Command	lsp-length originate <i>size</i> [level-1 level-2]
Parameter Description	<i>size</i> : Indicates the maximum length allowed for sent LSPs. The value range is 512 to 16,000, in the unit of bytes. level-1 : Applies the setting only to Level-1 LSPs. level-2 : Applies the setting only to Level-2 LSPs.
Command Mode	IS-IS routing process configuration mode
Usage Guide	In principle, the maximum length of LSPs and SNPs cannot be greater than the interface MTU; otherwise, the packets will be discarded when being sent.

↘ Configuring a Passive Interface

Command	passive-interface [default] { <i>interface-type interface-number</i> }
Parameter	default: Configures all IS-IS interfaces that are not enabled as passive interfaces.
Description	<i>interface-type:</i> Indicates the interface type. <i>interface-number:</i> Indicates the interface number.
Command Mode	IS-IS routing process configuration mode
Usage Guide	This command prevents the specified interface from receiving and sending IS-IS packets, but the IP address of the interface will be flooded by other interfaces. If the default option is selected and there are more than 255 IS-IS interfaces not enabled, only the first 255 interfaces will be configured as passive interfaces. The remaining interfaces are non-passive interfaces.

↘ Configuring the IS-IS Interface Metric

Command	isis metric <i>metric</i> [level-1 level-2]
Parameter	<i>metric:</i> Indicates the metric value. The value range is 1 to 63. The default value is 10.
Description	level-1: Applies the setting to Level-1 circuits. level-2: Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric belongs to the narrow type and is valid only when metric-style is set to Narrow .

↘ Configuring the Wide Metric of an Interface

Command	isis wide-metric <i>metric</i> [level-1 level-2]
Parameter	<i>metric:</i> Indicates the metric value. The value range is 1 to 16,777,214. The default value is 10.
Description	level-1: Applies the setting to Level-1 circuits. level-2: Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	The metric, which is used in SPF calculation, is stored in the IP reachability information TLV. The greater the metric, the greater the routing consumption of the interface and the longer the path obtained by SPF calculation. The metric is valid only when metric-style is set to Wide .

↘ Configuring the Priority of the DIS

Command	isis priority <i>value</i> [level-1 level-2]
Parameter	<i>value:</i> Indicates the priority. The value range is 0 to 127. The default value is 64.
Description	level-1: Applies the setting to Level-1 circuits.

	level-2: Applies the setting to Level-2 circuits.
Command Mode	Interface configuration mode
Usage Guide	<p>Use this command to change the priority carried in Hello packets in a LAN.</p> <p>The device with a lower priority is less likely to be elected as the DIS.</p> <p>The command is invalid on a P2P network interface.</p> <p>The no isis priority command, with or without parameters, restores the priority to its default value. To change the configured priority, run the isis priority command with the priority specified to overwrite the existing configuration, or you can first restore the priority to its default value and then configure a new priority.</p>

Generating a Default Route

Command	default-information originate [route-map <i>map-name</i>]
Parameter Description	route-map <i>map-name</i>: Associates with a route map.
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	Because Level-2 domains do not generate any default route, use this command to allow a default route to enter a Level-2 domain.

Configuring SPF Calculation Cycle

Command	spf-interval [level-1 level-2] <i>maximum-interval</i>
Parameter Description	<p>level-1: Applies the configuration only to Level-1.</p> <p>level-2: Applies the configuration only to Level-2.</p> <p><i>maximum-interval:</i> Indicates the maximum interval for performing two consecutive SPF calculations. The value range is 1 to 120 (in seconds). The default value is 10.</p>
Command Mode	IS-IS routing process configuration mode
Usage Guide	<p>Increasing the maximum interval for performing SPF calculations can avoid frequent SPF calculations and waste of CPU resources. However, a larger minimum interval also leads to slower responses to route changes.</p> <p>The waiting time for performing the SPF calculation for the first time is the initial interval. If the network becomes unstable, the SPF calculation interval is less than the maximum interval, and the interval for performing the SPF calculation for the second time becomes the hold interval. A corresponding penalty is added to this interval: The next interval for the SPF calculation doubles the previous interval for the same SPF calculation, until the SPF calculation interval reaches the maximum interval. Subsequent SPF calculations are performed at the maximum interval. When the network becomes stable, the interval for performing the SPF calculation becomes greater than the maximum interval, and the waiting time for performing the SPF calculation is restored to the initial interval.</p> <p>Link changes have high requirements for convergence. The initial interval can be set to a small value. The preceding parameters can also be adjusted to larger values to reduce CPU consumption.</p>

	<p>The value of initial-interval cannot be greater than that of maximum-interval. Otherwise, the value of initial-interval will be used as the value of maximum-interval.</p> <p>The value of hold-interval cannot be greater than that of maximum-interval. Otherwise, the value of hold-interval will be used as the value of maximum-interval.</p> <p>The value of initial-interval cannot be greater than that of hold-interval. Otherwise, the value of initial-interval will be used as the value of hold-interval.</p>
--	---

▾ **Configuring an IPv4 Summary Route**

Command	summary-address <i>ip-address net-mask</i> [level-1 level-2 level-1-2] [<i>metric number</i>]
Parameter Description	<p><i>ip-address</i>: Indicates the IP address of the summary route.</p> <p><i>net-mask</i>: Indicates the subnet mask of the summary route.</p> <p>level-1: Applies the setting only to Level-1.</p> <p>level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2.</p> <p>level-1-2: Applies the setting to Level-1 and Level-2.</p> <p><i>number</i>: Indicates the metric of the summary route.</p>
Command Mode	IS-IS routing process configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

▾ **Configuring an IPv6 Summary Route**

Command	summary-prefix <i>ipv6-prefix/prefix-length</i> [level-1 level-2 level-1-2]
Parameter Description	<p><i>ipv6-prefix/prefix-length</i>: Indicates the network address of the summary route and its IPv6 prefix length. The address format is X:X:X:X:/<0-128>.</p> <p>level-1: Applies the setting only to Level-1.</p> <p>level-2: Applies the setting only to Level-2. By default, the setting takes effect for Level-2.</p> <p>level-1-2: Applies the setting to Level-1 and Level-2.</p>
Command Mode	IS-IS address-family ipv6 configuration mode
Usage Guide	If the configured summary route contains routing information about a reachable address or network segment, the summary route, instead of detailed routes, is advertised externally.

▾ **Enabling Neighbor Relationship Event Output**

Command	log-adjacency-changes
Parameter Description	N/A
Command Mode	IS-IS routing process configuration mode
Usage Guide	You can also use the debug command to record IS neighbor state changes, but the command consumes many system resources.

↘ Redistributing Other Routes to IS-IS

Command	redistribute { bgp ospf <i>process-id</i> [match { internal [external [1 2]] [nssa-external [1 2]] external [1 2] [internal] [nssa-external [1 2]] nssa-external [1 2] [internal] [external [1 2]] }] rip connected static } [metric <i>metric-value</i>] [metric-type <i>type-value</i>] [route-map <i>map-tag</i>] [level-1 level-1-2 level-2]
Parameter Description	<p><i>process-id</i>: Indicates the OSPF process ID. The range is 1 to 65,535.</p> <p>match { internal external [1 2] nssa-external [1 2] }: When OSPF routes are redistributed, the routes are filtered by subtype. If the match option is not selected, routes of all OSPF types will be received. If match external is not followed by the number 1 or 2, OSPF routes specified by external 1 and external 2 will be redistributed. If match nssa-external is not followed by the number 1 or 2, OSPF routes specified by nssa-external 1 and nssa-external 2 will be redistributed.</p> <p>metric <i>metric-value</i>: Indicates the metric of redistributed routes. The value range is 0 to 4,261,412,864. The metric of external routes is used when the metric option is not specified.</p> <p>metric-type { internal external }: Indicates the metric type of redistributed routes. internal: Indicates that the metric belongs to the internal type. external: Indicates that the metric belongs to the external type. If metric-type is not specified, the metric belongs to the internal type.</p> <p>route-map <i>map-tag</i>: Indicates the route map used for external route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>map-tag</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>level-1 level-1-2 level-2: Indicates the Level of redistributed routes received by IS-IS. If no Level is specified, routes are redistributed to Level-2. level-1: Redistributes routes to Level-1. level-1-2: Redistributes routes to Level-1 and Level-2. level-2: Redistributes routes to Level-2.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	<p>The no redistribute { bgp ospf <i>process-id</i> rip connected static } command is used to cancel the redistribution of routes mapped to the specified protocol. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution. For example, no redistribute bgp cancels BGP route redistribution, whereas no redistribute bgp route-map aa cancels the route map named aa used for BGP route redistribution.</p> <p>When external routes are redistributed in IPv4 mode, the routing information is stored in LSPs' IP External Reachability Information TLV.</p> <p>When external routes are redistributed in IPv6 mode, the routing information is stored in LSPs' IPv6 Reachable TLV.</p> <p>In the old versions of some vendors, if metric-type is set to external, the metric of redistributed routes is added by 64 during route calculation and used to determine routing. This practice does not comply with the related protocol. In the actual application, external routes may be preferred over internal routes. If this happens during interworking with old versions of some vendors, you can modify the related setting (such as metric or metric-type) of each device to ensure that internal routes are preferred over external routes.</p>

↘ Redistributing the Level-1 Reachable Routing Information of the Specified IS-IS Instance to Level-2 of the Current Instance

Command	redistribute isis [<i>tag</i>] level-1 into level-2 [route-map <i>route-map-name</i> distribute-list <i>access-list-name</i>]
Parameter Description	<p><i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed.</p> <p>route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode
Usage Guide	<p>You can use the route-map or distribute-list parameter to filter the specified instance's Level-1 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-2 of the current instance. The route-map and distribute-list parameters cannot be used at the same time.</p> <p>The no redistribute isis [<i>tag</i>] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution.</p> <p>For example, no redistribute isis <i>tag1</i> level-1 into level-2 cancels the redistribution of the routes of the IS-IS instance name <i>tag1</i>. no redistribute isis <i>tag1</i> level-1 into level-2 route-map <i>aa</i> cancels the use of the route map named <i>aa</i> to filter redistributed routes.</p>

↘ **Redistributing the Level-2 Reachable Routing Information of the Specified IS-IS Instance to Level-1 of the Current Instance**

Command	redistribute isis [<i>tag</i>] level-2 into level-1 [route-map <i>route-map-name</i> distribute-list <i>access-list-name</i>] (prefix <i>ip-address net-mask</i> ipv6-prefix <i>ipv6-address/length</i>)]
Parameter Description	<p><i>tag</i>: Indicates the name of the IS-IS instance whose routing information will be redistributed.</p> <p>route-map <i>route-map-name</i>: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of <i>route-map-name</i> cannot exceed 32 characters. By default, route-map is not configured.</p> <p>Distribute-list <i>access-list-name</i>: Filters redistributed routes by using distribute-list. <i>access-list-name</i> indicates the associated prefix list, which can be a standard prefix list, an extended prefix list, or a name prefix list. It is in the format of {<1-99> <100-199> <1300-1999> <2000-2699> <i>acl-name</i> }. When the IS-IS address-family ipv6 configuration mode is applied, only the name prefix list can be used, in the format of <i>acl-name</i>.</p> <p>prefix <i>ip-address net-mask</i>: Determines the routes to be redistributed by address and prefix length.</p> <p>ipv6-prefix <i>ipv6-address/length</i>: Determines the IPv6 routes to be redistributed by address and prefix length.</p>
Command Mode	IS-IS routing process configuration mode and IS-IS address-family ipv6 configuration mode

Usage Guide	<p>You can use the route-map, distribute-list, or prefix parameter to filter the specified instance's Level-2 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-1 of the current instance.</p> <p>The no redistribue isis [tag] level-2 into level-1 command is used to cancel the redistribution of the specified instance's routes. If no redistribute is followed by other parameters, the command will restore the default parameter settings, rather than cancel route redistribution.</p> <p>For example:</p> <p>no redistribue isis tag1 level-2 into level-1 cancels the redistribution of the routes of the IS-IS instance name tag1. no redistribue isis tag1 level-2 into level-1 route-map aa cancels the use of the route map named aa to filter redistributed routes.</p>
--------------------	--

Configuration Example

Configuring the Maximum Number of Equal-Cost Paths

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure the maximum number of equal-cost paths.
	<pre>A(config)# router isis A(config-router)# maximum-paths 5</pre>
Verification	<ul style="list-style-type: none"> Check whether the maximum number of equal-cost paths displayed by routing entries is the same as the configuration.
	<pre>A# show ip route isis</pre>

Configuring the Maximum Length Allowed for Received LSPs

Configuration	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure the maximum length allowed for received LSPs.
	<pre>A(config)# router isis A(config-router)# lsp-length receive 512</pre>
Verification	Capture packets to check the length of received LSPs.

Configuring the Maximum Length Allowed for Sent LSPs

Configurations	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configure the maximum length allowed for sent LSPs.
-----------------------	---

	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# lsp-length originate 512 level-2</pre>
Verification	Capture packets to check the length of sent LSPs.

↘ Configuring a Passive Interface

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure a passive interface.
	<pre>A# configure terminal A(config)# router isis 1 A(config-router)# passive-interface GigabitEthernet 0/0</pre>
Verification	Capture packets to check whether the interface receives and sends IS-IS packets.

↘ Configuring the Metric of an IS-IS Interface

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure metric of the IS-IS interface.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)#isis metric 1</pre>
Verification	Check the database details of IS-IS.
	<pre>A# show isis database detail</pre>

↘ Configuring the Priority of the DIS

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure the priority of the DIS.
	<pre>A(config)# interface GigabitEthernet 0/1 A(config-if)# isis priority 127 level-1</pre>
Verification	Check whether the device with the changed priority setting is elected as the DIS.
	<pre>A# show isis database detail</pre>

➤ **Generating a Default Route**

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Generate a default route.
	<pre>A(config)# router isis A(config-router)# default-information originate</pre>
Verification	Capture packets to check whether the sent LSP contains a default route.

➤ **Configuring SPF Calculation Cycle**

Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS neighbors. (Omitted) Configuring SPF calculation cycle.
	<pre>A(config)# router isis A(config-router)# spf-interval 5 100 200</pre>
Verification	Check whether the SPF calculation cycle works.

➤ **Configuring an IS-IS Summary Route**

Configuration Requirements	Router A and Router B are connected through the Ethernet and run IS-IS. Configure Router A to advertise only the 172.16.0.0/22 route instead of the 172.16.1.0/24 and 172.16.2.0/24 routes.
Figure 4-20 IS-IS Route Summary Topology	
Configuration Steps	<ul style="list-style-type: none"> Configure IS-IS. Configure Ethernet interfaces. Configure the password for IS-IS authentication.
A	Configure IS-IS.
	<pre>A(config)# router isis</pre>

	<pre>A(config-router)# net 49.0001.0000.0000.0001.00 A(config-router)# summary-address 172.16.0.0/16 level-1-2</pre>
	<p>Configure Ethernet interfaces.</p> <pre>A(config)# interface GigabitEthernet 0/0 A(config-if)# ip address 192.168.20.1 255.255.255.0 A(config-if)# ip router isis A(config)# interface GigabitEthernet 1/0 A(config-if)# ip address 172.16.1.1 255.255.255.0 A(config-if)# ip router isis A(config)# interface GigabitEthernet 1/1 A(config-if)# ip address 172.16.2.1 255.255.255.0 A(config-if)# ip router isis</pre>
B	<p>Configure IS-IS.</p> <pre>B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00</pre>
	<p>Configure an Ethernet interface.</p> <pre>B(config)# interface GigabitEthernet 0/0 B(config-if)# ip address 192.168.20.2 255.255.255.0 B(config-if)# ip router isis</pre>
Verification	<p>Run the show ip route command on Router B to check whether only one summary route exists.</p>
B	<pre>B(config)# show ip route i L1 172.16.0.0/16 [115/20] via 192.168.20.1, FastEthernet0/0</pre>

📌 **Configuring an IS-ISv6 Summary Route**

	<p>Router A and Router B are connected through the Ethernet and run IS-ISv6. Configure Router A to advertise only the 2000::/96 route instead of the 2000::1111:0/112 and 2000::2222::0/112 routes.</p>
Figure 4-21 IS-ISv6 Route Summary Topology	

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IS-IS. ● Configure Ethernet interfaces. ● Configure the password for IS-IS authentication.
<p>A</p>	<p>Configure IS-IS.</p>
	<pre>A(config)# ipv6 unicast-routing A(config)# router isis A(config-router)# net 49.0001.0000.0000.0001.00 A(config-router)# address-family ipv6 unicast A (config-router-af)# summary-prefix 2000::/96 level-1-2 A (config-router-af)# exit-address-family</pre>
	<p>Configure Ethernet interfaces.</p> <pre>A(config)# interface GigabitEthernet 0/0 A(config-if)# ipv6 address 5000::1/64 A(config-if)# ipv6 router isis A(config)# interface GigabitEthernet 1/0 A(config-if)# ipv6 address 2000::1111:0001/112 A(config-if)# ipv6 router isis A(config)# interface GigabitEthernet 1/1 A(config-if)# ipv6 address 2000::2222:0001/112 A(config-if)# ipv6 router isis</pre>
<p>B</p>	<p>Configure IS-IS.</p>
	<pre>B(config)# ipv6 unicast-routing B(config)# router isis B(config-router)# net 49.0001.0000.0000.0002.00</pre>
	<p>Configure an Ethernet interface.</p>

	<pre>B(config)# interface GigabitEthernet 0/0 B(config-if)# ipv6 address 5000::2/64 B(config-if)# ipv6 router isis</pre>
Verification	Run the show ipv6 route command on Router B to check whether only one summary route exists.
B	<pre>B(config)# show ipv6 route I1 2000::/96 [115/20] via FE80::C800:1BFF:FEF8:1C, FastEthernet1/0</pre>

📌 **Enabling Neighbor Relationship Event Output**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Enable neighbor relationship event output.
	<pre>A(config-router)# log-adjacency-changes</pre>
Verification	Change the neighbor state and verify that the change is recorded when debugging is disabled.

📌 **Configuring Route Redistribution**

Configuration Steps	<ul style="list-style-type: none"> ● Configure IS-IS neighbors. (Omitted) ● Configure OSPF routes. (Omitted) ● Configure route redistribution
	<pre>A(config)# router isis A(config-router)# redistribute ospf 1 metric 10 level-1</pre>
Verification	Check whether routing entries with redistributed routes exist.
	<pre>A# show ip route isis</pre>

4.5 Monitoring

Clearing

⚠️ Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears all IS-IS neighbor relationship tables.	clear clns neighbors

Clears all IS-IS data structures.	clear isis *
Clears all IS-IS counters.	clear isis [tag] counter

Displaying

Description	Command
Displays all IS neighbors and inter-device neighbor relationships.	show clns [tag] is-neighbors [interface-type interface-number] [detail]
Displays all IS neighbors and provides device information and information about the neighbor relationship with ESs.	show clns [tag] neighbors [interface-type interface-number] [detail]
Displays all IS-IS counters.	show isis [tag] counter
Displays the LSDB information.	show isis [tag] database [FLAGS] [LEVEL] [LSPID]
Displays the state information related to IS-IS GR.	show isis [tag] graceful-restart
Displays the relationship between the device name and system ID.	show isis [tag] hostname
Displays the details of an IS-IS interface.	show isis [tag] interface [interface-type interface-number] [counter]
Displays the mesh group configuration of all interfaces.	show isis [tag] mesh-groups
Displays IS-IS neighbor information.	show isis [tag] neighbors [detail]
Displays the neighbor information of virtual systems in IS-IS.	show isis [tag] virtual-neighbors
Displays IS-IS information.	show isis [tag] protocol
Displays the topology of IS-IS device connection.	show isis [tag] topology [I1 I2 level-1 level-2]
Displays information of an IS-IS IPv6 unicast topology.	show isis [tag] ipv6 topology [I1 I2 level-1 level-2]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables IS-IS debugging.	debug isis { all auth events gr ifsm lsp mtr nfm nsm pdu spf warn }

5 Configuring BGP

5.1 Overview

The Border Gateway Protocol (BGP) is an Exterior Gateway Protocol (EGP) used for communication between routers in different autonomous systems (ASs). BGP is used to exchange network accessibility information between different ASs and eliminate routing loops by using its own mechanism.

BGP uses TCP as the transmission protocol. The reliable transmission mechanism of TCP is used to ensure the transmission reliability of BGP.

Routers running BGP are called BGP speakers. BGP speakers between which a BGP session is established are called BGP peers.

Two modes can be used to establish peers between BGP speakers: Internal BGP (IBGP) and External BGP (EBGP).

- IBGP refers to a BGP connection established within an AS and completes transition of routing information within the AS.
- EBGP refers to a BGP connection established between different ASs and completes exchange of routing information between different ASs.

Rules for BGP to select an optimum route:

5. Invalid routing table entries are not involved in optimum route selection.

 Invalid entries include entries of inaccessible next hops and flapping entries.

6. Otherwise, select a route with a large value of **LOCAL_PREF**.

7. Otherwise, select a route generated by a BGP speaker.

 Routes generated by a BGP speaker include routes generated by the **network**, **redistribute** and **aggregate** commands.

8. Otherwise, select a route with the shortest AS length.

9. Otherwise, select a route with a smaller value of **ORIGIN**.

10. Otherwise, select a route with the smallest value of **MED**.

11. Otherwise, EBGP routes have higher priorities than IBGP routes and routes in the AS alliance, and the IBGP routes have the same priorities as the routes in the AS alliance.

12. Otherwise, select a route with the smallest IGP metric value to the next hop.

13. Otherwise, select an EBGP route that is received first.

14. Otherwise, select a route advertised by a BGP speaker with a smaller router ID.

15. Otherwise, select a route with a large cluster length.

16. Otherwise, select a route with a large neighbor address.

i The preceding shows the route selection process under the default configurations. By using CLI commands, you can change the route selection process. For example, you can run the **bgp bestpath as-path ignore** command to make step 4 of the route selection process lose effect or run the **bgp bestpath compare-routerid** command to make step 9 lose effect.

Protocols and Standards

- RFC4271: A Border Gateway Protocol 4 (BGP-4)
- RFC4273: Definitions of Managed Objects for BGP-4
- RFC4360: Proposed Standard: BGP Extended Communities Attribute
- RFC4364: Proposed Standard: BGP/MPLS IP Virtual Private Networks (VPNs)
- RFC4486: Proposed Standard: Subcodes for BGP Cease Notification Message
- RFC4724: Proposed Standard: Graceful Restart Mechanism for BGP
- RFC4760: Draft Standard: Multiprotocol Extensions for BGP-4
- RFC5492: Draft Standard: Capabilities Advertisement with BGP-4
- RFC7432: Proposed Standard: BGP MPLS-based Ethernet VPN

5.2 Applications

Application	Description
Inter-AS Route Advertisement	Implement inter-AS route advertisement by using BGP.
Intra-AS Route Reflection	Set up a route reflection topology within an AS to reduce BGP connections.

5.2.1 Inter-AS Route Advertisement

Scenario

BGP implements route advertisement and maintenance across different ASs.

As shown in Figure 5-1, BGP transfers the route of AS 65536 to AS 65538 through AS 65537.

Figure 5-1

Remarks	R1 is a device at the network edge of AS 65536. R2 and R3 are devices at the network edge of AS 65537. R4 is a device at the network edge of AS 65538.
----------------	--

Deployment

- Establish the EBGP neighborship between R1 and R2 to implement inter-AS route advertisement.
- Establish the IBGP neighborship between R2 and R3 to implement intra-AS route advertisement.
- The Internet runs OSPF to ensure network accessibility between R2 and R3.
- Establish the EBGP neighborship between R3 and R4 to implement inter-AS route advertisement.

5.2.2 Intra-AS Route Reflection

Scenario

According to the BGP route advertisement principles, routes learned by an IBGP neighbor will not be advertised to the next IBGP neighbor by default. Therefore within an AS, a device running BGP must implement full-mesh. When there are many BGP devices within the AS, implementing full-mesh may cause large difficulties for network deployment. In this case, route reflection can be used to solve this problem.

As shown in Figure 5-2, route reflection is deployed to implement BGP full-mesh among R1 to R4 and RR.

Figure 5-2

Remarks	RR is a route reflector. R1 to R4 are route reflection clients.
----------------	--

Deployment

- Establish IBGP neighborships between R1 to R4 and RR respectively.
- Configure R1 to R4 as the route reflection clients of RR.

5.3 Features

Basic Concept

↘ BGP Speaker and AS Number

A router enabled with BGP is called a BGP speaker.

After a router is enabled with BGP, a local AS number must be specified for the router. An AS number is a globally unique number allocated by IANA, ranging from 1 to 4294967295.

↘ BGP Neighbor and Peer

Before a route is advertised between BGP speakers, a neighborhood must be established in advance. You need to manually configure BGP neighbors on both BGP speakers. That is, configure the peer as a neighbor on the two BGP speakers respectively. Therefore, BGP neighbors are also called BGP peers.

↘ Neighbor Type and Route Type

BGP neighborhoods are classified into the following types:

- IBGP neighborhood: The neighborhood between BGP speakers within an AS is called IBGP neighborhood. Routes learned from IBGP neighbors are called IBGP routes.
- EBGP neighborhood: The neighborhood between BGP speakers in different ASs is called EBGP neighborhood. Routes learned from EBGP neighbors are called EBGP routes.

↘ BGP route attribute

When a BGP speaker advertises routes to its neighbors, the BGP speaker also advertises the attributes carried by the routes. Common BGP attributes are as follows:

- ORIGIN: Specifies the origin of a BGP route and can be set to **IGP**, **EGP**, or **INCOMPLETE**.
- AS-PATH: Lists the ASs passed by a route in a reverse order. The last AS is placed at the beginning of the list.
- NEXT-HOP: Specifies the IP address of the next hop to be reached by a BGP route.
- MULTI-EXIT-DISC: Distinguishes multiple output/input interfaces for reaching the same neighbor AS. A smaller value means a higher priority.
- LOCAL-PREF: Distinguishes the priorities of IBGP routes in an AS. A larger value means a higher priority.

Overview

Feature	Description
Creating a BGP Neighbor	Create a BGP neighbor.
Configuring a BGP Route Reflector	Set up a BGP route reflection topology to simplify network deployment for BGP neighbor full-mesh.
Configuring a BGP Alliance	Configure a BGP alliance to simplify network deployment for BGP neighbor full-mesh.
Re-distributing Local AS Network Information to BGP	Re-distribute routing information to BGP and advertise local routes through BGP.
Controlling Route Exchange Between BGP Peers	Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.

Feature	Description
Obtaining Accessible Networks of Other ASs from BGP	Re-distribute routing information in BGP into a core routing table or IGP.
Configuring Synchronization Between BGP and IGP	Configure BGP to check whether BGP routes are synchronized with IGP routes.
Configuring BGP Soft Reset	After a routing policy changes, use soft reset to apply a new policy.
Configuring the Route Attributes of BGP	Configure the route selection algorithms and routing policy control of BGP.
Configuring BGP Route Aggregation	Reduce routes by means of route aggregation.
Configuring BGP Route Dampening	Reduce the impacts of route flapping on a network topology.
Configuring the Management Distance of BGP	Change the priorities of BGP routes.
Configuring Multi-path Load Balancing of BGP	Configure multi-path load balancing for BGP to enhance the network reliability and increase the network bandwidth.
Configuring BGP FRR	Configure fast rerouting for BGP to enhance the network reliability.
Configuring BGP Timers	Modify the internal timer time of BGP.
Configuring BGP Route Update Mechanisms	Disable/Enable regular scanning for BGP routes and configure the route scanning interval.
Configuring the Next-Hop Triggering Update Function of BGP	Configure the next hop triggering update function of BGP.
Configuring BGP LOCAL AS	Configure the LOCAL AS for a BGP neighbor.
Configuring BGP Capacity Protection	Avoid non-predictable running status caused by consumption of device capacity.
Configuring BGP GR	Configure the BGP GR function to enhance the network reliability.
Configuring 4-Byte AS Numbers of BGP	Configure the display mode of a 4-byte AS number.
Configuring a Regular Expression	Use a regular expression to filter routing information.
Configuring BGP Session Retention	Configure BGP to ensure that after an address family with incorrect routing attributes is detected for a neighbor, other address family routes advertised by the neighbor will not be affected.

Feature	Description
Configuring BGP Delayed Advertisement upon System Restart	Configure BGP to delay route advertisement to a neighbor within a period after the system is restarted.
Other Related Configurations	Configure extended BGP functions.

5.3.1 Creating a BGP Neighbor

A BGP neighbor is manually configured by a user. Two connection modes are supported: IBGP and EBGP. You can identify the connection mode between BGP speakers based on the AS where the BGP peer resides and the AS where the BGP speaker resides.

- i** Generally, BGP speakers between which an EBGP connection is established are directly connected whereas BGP speakers between which an IBGP connection is established can be at any location within an AS.

Working Principle

A BGP speaker can initiate a TCP connection request to a BGP peer specified by a user. After the TCP connection is successfully created, the peers will exchange BGP packets to negotiate about connection parameters. The BGP neighborhood is successfully established after the negotiation succeeds.

↳ Creating a TCP Connection

A BGP speaker initiates a TCP connection request to a neighbor. The destination IP address is the peer IP address specified by the user and the port number is fixed to 179.

The BGP speaker also listens on the port number 179 of the local TCP connection to receive connection requests from its peer.

↳ Negotiating about Protocol Parameters

After the TCP connection is successfully created, the BGP speakers exchange OPEN packets to negotiate about BGP connection parameters. The parameters for negotiation include:

- **Version:** Indicates the BGP version number. At present, only version 4 is supported.
- **Neighbor AS number:** Determines whether the AS number of the neighbor is consistent with the local AS number. If not, the connection request will be denied.
- **Hold Time:** Negotiates about the timeout duration for the BGP connection. The default value is 180 seconds.
- **Neighbor capability:** Negotiates about various extended capabilities supported by the neighbor, including the address family, dynamic route update, and GR functions.

↳ Maintaining Neighborhood

The Keepalive message is periodically sent between BGP speakers. If a new Keepalive packet is not received from the BGP neighbor after the Hold Time expires, the BGP speaker considers that the neighbor is not accessible, disconnects the TCP connection from the neighbor, and attempts to reconnect to it. The interval for a BGP speaker to send the Keepalive message is one third of the Hold Time determined through negotiation and is 60 seconds by default.

Related Configuration

↘ Creating a BGP Neighbor

By default, a BGP speaker does not specify any neighbor. You can manually configure a BGP neighbor.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify the AS number of the neighbor.

↘ Setting the Neighbor TTL

By default, The TTL field in a TCP packet sent by an IBGP neighbor is set to the maximum value (255). It is set to 1 by an EBGP neighbor.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **ebgp-multihop** [*ttl*] command to set the TTL field of a TCP packet sent by a BGP neighbor.

A larger value of TTL means a longer distance between BGP neighbors. When TTL is 1, the BGP neighbor devices must be directly connected.

↘ Setting the Source Address of TCP

By default, BGP automatically selects the source IP address of a TCP connection based on the IP address of the neighbor. Generally, the IP address of a local packet output interface is used.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *address* } command to adjust the source IP address of the neighbor's TCP connection.

↘ Setting MD5 Encryption

By default, a BGP connection is not encrypted through MD5.

You can run the **neighbor** { *peer-address* | *peer-group-name* } **password** [*0* | *7*] *string* command to set encryption for a BGP neighbor's TCP connection.

↘ Activating the Address Family Capability of a Neighbor

By default, a neighbor created in the BGP configuration mode activates only the IPv4 Unicast address family capability.

You can run the **address-family** command to enter a corresponding address family mode, and then run the **neighbor** { *peer-address* | *peer-group-name* } **activate** command to activate the address family capability for the BGP neighbor.

5.3.2 Configuring a BGP Route Reflector

According to the principle of BGP route advertisement, full mesh must be established for all BGP speakers within an AS (neighborships need to be established between each two BGP speakers). Too many BGP speakers within an AS will increase the resource overhead of the BGP speakers, increase the network administrator's workload and complexity of configuration and decrease the network expansion capability.

Using a route reflector is a method for reducing IBGP peer connections within an AS.

-
- i** The methods for reducing the IBGP peer connections within an AS include using a route reflector and using an AS alliance.
-

Working Principle

Configure a BGP speaker as a route reflector which classifies IBGP peers in an AS into two types: clients and non-clients.

The rules for implementing a route reflector within an AS are as follows:

- Configure a route reflector and specify clients for the route reflector. The route reflector and its clients form a cluster. The route reflector will connect to its clients.
- The clients of a route reflector in a cluster cannot connect to other BGP speakers out of the cluster.
- Within an AS, full mesh is established among IBGP peers of non-clients. The IBGP peers of non-clients include the following situations: Multiple route reflectors in a cluster; a route reflector in a cluster and BGP speakers (generally not supporting the route reflector function) not involved in the route reflector function out of the cluster; a route reflector in a cluster and route reflectors in other clusters.

The rules for processing a route received by a route reflector are as follows:

- A route update message received by an EBGP speaker will be sent to all clients and non-clients.
- A route update message received by a client will be sent to other clients and all non-clients.
- A route update message received by an IBGP speaker will be sent to all the other clients.

-
- i** Generally, only one route reflector is configured in a cluster. In this case, the Router ID of the route reflector can be used to identify this cluster. To increase the redundancy, you can set multiple route reflectors in a cluster. In this case, you must configure the cluster ID so that a route reflector can identify the route update messages from other route reflectors in the cluster.

- i** If multiple route reflectors are configured for a cluster, you must configure a cluster ID for the cluster.

- i** Generally, it is unnecessary to create connections between the clients of a route reflector in a cluster because the route reflector will reflect the routes between the clients. However, if full mesh has been established among all clients, you can cancel the client route reflection function of the route reflector.
-

Related Configuration

↘ Configuring a BGP Route Reflector and Reflected Clients

By default, BGP is not configured with route reflection.

You can run the **neighbor peer-address route-reflector-client** command to configure a device as a route reflector and its neighbor devices as reflected clients.

↘ Configuring BGP Client-Client Reflection

By default, BGP client-client route reflection is enabled, which means that routes received from a reflected client can be advertised to other clients.

You can run the **bgp client-to-client reflection** command to enable or disable (using the **no** form of this command) client-client reflection.

▾ [Configuring a BGP Reflection Cluster ID](#)

By default, a BGP reflection cluster ID is the Router-ID of BGP. If multiple reflection clusters are deployed within an AS, different reflection cluster IDs must be configured for these reflection clusters.

You can run the **bgp cluster-id** *cluster-id* command to manually configure the cluster ID of a route reflector.

5.3.3 Configuring a BGP Alliance

An alliance is another method for reducing the IBGP peer connections within an AS.

Working Principle

Divide an AS into multiple sub ASs and configure a unified alliance ID (namely, the alliance AS NUMBER) for these sub ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, full mesh of IBGP peers can be established for BGP speakers within a sub AS, and EBGP connections can be established for BGP speakers in different sub ASs. Though EBGP connections are established between BGP speakers within a sub AS, when information is exchanged, NEXT_HOP, MED, LOCAL_PREF and other path attributes keep unchanged.

Related Configuration

▾ [Configuring a BGP Alliance ID](#)

By default, no alliance ID is configured for a BGP speaker.

You can run the **bgp confederation identifier** *as-number* command to configure a BGP alliance ID. After the configuration is successful, the local AS (specified by the **router bgp** *as-number* command) of BGP becomes the private AS inside the alliance and is invisible to other ASs.

▾ [Configuring a BGP Alliance Neighbor](#)

By default, no alliance neighbor is configured for BGP.

You can run the **bgp confederation peers** *as-number* [...] *as-number* command to configure a BGP alliance neighbor. After the configuration succeeds, the AS specified by this command and the local AS belong to the same alliance.

5.3.4 Re-distributing Local AS Network Information to BGP

BGP cannot automatically discover or learn accessible networks. The accessible network information of a local AS must be re-distributed to BGP. Then, BGP can advertise the information to neighbors.

Working Principle

Two methods can be used to re-distribute local AS network information to BGP:

- Manual static configuration: re-distribute the accessible network information within a specified range to BGP.

- Configuring route re-distribution: re-distribute accessible IGP network information to BGP.

 In addition, you can also re-distribute local AS network information to BGP routes by configuring route aggregation.

Related Configuration

↳ Configuring a BGP Network

By default, no network is configured for BGP.

You can run the **network** *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**] command to configure a BGP network to re-distribute specified accessible network information to BGP. The prerequisite for successfully re-distributing routing information to BGP is that a route is available in the core routing table and this route can be an IGP, directly-connected or static route.

↳ Configuring BGP Route Re-distribution

By default, BGP is not configured with route re-distribution.

You can run the **redistribute** *protocol-type* command to re-distribute the routing information of other protocols to BGP, including OSPF, RIP, ISIS, static and directly-connected routes.

5.3.5 Controlling Route Exchange Between BGP Peers

BGP provides powerful route management functions. You can actively control the route exchange between BGP peers.

Working Principle

Configure the route exchange policy for a BGP peer and control routes to be received by and to be advertised to this peer.

Related Configuration

↳ Configuring the Default Route to Be Advertised to a Peer

By default, BGP does not advertise the default route.

You can run the **neighbor** { *address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*] command to advertise the default route to a peer (or a peer group).

↳ Configuring Next-Hop-Self for a Peer

By default, BGP does not change the next hop of a route when it advertises the route to an IBGP neighbor and sets the next hop to the local BGP speaker when it advertises the route to an EBGP neighbor.

You can run the **neighbor** { *address* | *peer-group-name* } **next-hop-self** command to configure the next hop of a route to the local BGP speaker when distributing the route to a specified BGP peer (group).

↳ Configuring Remove-Private-AS for a Peer

By default, BGP does not delete the private AS in the AS-PATH attribute when it advertises routing information to a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **remove-private-as** command to require that the private AS number recorded in the AS path attribute should be deleted when routing information is distributed to an EBGp peer (group). This command does not apply to an IBGP neighbor.

↘ Configuring Send-Community for a Peer

By default, BGP does not send the community attribute when it advertises routing information to a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **send-community** command to specify that the community attribute can be sent to a specified BGP peer (group).

↘ Configuring Maximum-Prefix for a Peer

By default, BGP does not restrict the records of routing information that can be received by a peer.

You can run the **neighbor** { *address* | *peer-group-name* } **maximum-prefix** *maximum* [**warning-only**] command to specify the records of routing information received from a specified peer (group).

↘ Configuring Route Filtering for a BGP Neighbor

By default, a BGP neighbor is not enabled with any filtering policy and receives all legal routing information advertised by a neighbor.

BGP supports multiple methods of configuring the route filtering policies for a neighbor, including:

- **neighbor** { *peer-address* | *peer-group-name* } **distribute-list** { *access-list-number* | *access-list-name* } { **in** | **out** }
Use an ACL to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **filter-list** *access-list-number* { **in** | **out** }
Use an AS-PATH list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }
Use a prefix-list to filter routes in the input and output directions of the neighbor.
- **neighbor** { *peer-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }
Use a route map to filter routes in the input and output directions of the neighbor.
- **neighbor** { *address* | *peer-group-name* } **unsuppress-map** *map-tag*
Allow for advertising certain routing information previously suppressed by the **aggregate-address** command when distributing routing information to a specified peer.

5.3.6 Obtaining Accessible Networks of Other ASs from BGP

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Send routing information of other ASs exchanged by BGP to the routing table of a device so that the device can forward packets to other ASs.

Working Principle

↘ BGP Sends Routing Information to a Core Routing Table

BGP controls routing information sent to the core routing table by using **table-map**. **table-map** can modify the attributes of routing information sent to the core routing table. If the route is matched, BGP modifies the attribute of the routing information and sends the route. If the route is not matched or route matching is denied, BGP does not modify the attribute of the routing information but sends the route.

Changes of **table-map** are not reflected in the core routing table immediately, but reflected a moment later. To update the application of **table-map** immediately, you can run the **clear ip bgp [vrf vrf-name] table-map** command to update the routing information in the core routing table immediately. This command does not clear the existing routes in the core routing table, but directly applies **table-map** to send the updated routing information, thereby not causing forwarding flapping.

↘ Re-distributing BGP Routes to IGP

Re-distribute BGP routes on a BGP speaker to IGP to ensure that routers within an AS can obtain routes to other ASs.

Related Configuration

↘ Configuring table-map

By default, BGP is not configured with a table-map and allows for sending all routes without modifying the attributes of the routes.

You can run the **table-map route-map-name** command to set a table-map and control the routing information to be sent to the core routing table. *route-map-name* specifies a route-map to be associated.

-
- Run the **table-map** command in the BGP configuration mode or in the IPv4 address family mode.

The Match and Set statements supported in the table-map are as follows:

Match statements: as-path, community, ip address, ip next-hop, metric, origin and route-type

Set statements: metric, tag and next-hop

- You can run the **no table-map** command to delete the table-map configurations.
-

↘ Configuring BGP Route Re-distribution by IGP

By default, IGP does not re-distribute BGP routes.

You can run the **redistribute bgp [route-map map-tag] [metric metric-value]** command to re-distribute BGP routes to IGP (RIP\OSPF\ISIS).

The **bgp redistribute-internal** command controls only whether to re-distribute routes learned from IBGP to IGP. By default, routes learned from IBGP can be re-distributed to IGP.

-
- You can run the **bgp redistribute-internal** command in the BGP configuration mode, IPv4/IPv6 address family mode or the IPv4 VRF address family mode.

- You can run the **no bgp redistribute-internal** command to delete the configuration.
-

5.3.7 Configuring Synchronization Between BGP and IGP

Generally, BGP speakers working as mutual IBGP neighbors are not directly connected. IGP devices between the BGP speakers may fail to learn routing information same as that learned by the BGP speakers. When a BGP speaker at the border of an AS forwards packets received from other domains to the next-hop IBGP neighbor, the packets pass an IGP device in the middle. In this case, the packets may be lost due to no routing information on the IGP device.

Working Principle

To keep synchronization between BGP and IGP, you must ensure that all routers within an AS can learn routing information to be sent to another AS before the routing information is advertised to this AS.

Synchronization between BGP and IGP is not required only in the following cases:

- Routing information passing through an AS is not available. For example, the AS is an end AS.
- All routers within an AS run BPG. Full mesh is established among all BGP speakers (neighborship is established between each two BGP speakers).

Related Configuration

📄 Configuring BGP Route Synchronization

By default, synchronization between BGP and IBGP routes is disabled.

You can run the **synchronization** command to enable synchronization between BGP and IGP.

You can run the **no synchronization** command to disable synchronization between BGP and IGP.

5.3.8 Configuring BGP Soft Reset

If routing policies (including **neighbor distribute-list**, **neighbor route-map**, **neighbor prefix-list** and **neighbor filter-list**) change, an effective method must be provided to implement new routing policies. A traditional method is to terminate a BGP connection and then create a new BGP connection. By configuring BGP Soft Reset, you can execute a new routing policy without terminating a BGP session connection.

Working Principle

- 📘 Routing policies that affect inbound routing information are called inbound routing policies (such as In-route-map and In-dist-list) and routing policies that affect outbound routing information are called outbound routing policies (such as Out-route-map and Out-dist-list).

When outbound routing policies change, BGP soft reset will re-advertise all routing information of a BGP speaker to its neighbors.

If inbound routing policies change, the operation is more complex than that when outbound routing policies change. This is because outbound routing policies are executed in the routing table of the local BGP speaker whereas inbound routing policies are executed for routing information received from the BGP peer. To reduce cost, the local BGP speaker does not store the original routing information received from the BGP peer.

If inbound routing policies change and a neighbor device supports route update, you can configure soft reset to send a route update request to the neighbor device. After receiving the request, the neighbor device re-advertises all routing information. You can also perform configuration to ensure that each BGP peer stores original routing information on the local BGP speaker and provides original routing information basis for modifying inbound routing policies subsequently.

-
- i** The "route update capability" allows for modifying and executing routing policies without storing original routing information. This product supports the route update capability. You can run the **show ip bgp neighbors** command to check whether a BGP peer supports route update. If yes, you do not need to run the **neighbor soft-reconfiguration inbound** command when inbound routing policies change.
-

Related Configuration

↳ Configuring BGP Soft Reset

Run the **clear ip bgp** { * | *peer-address* | **peer-group** *peer-group-name* | **external** } **soft out** command to soft reset a BGP connection. You can activate execution of a routing policy without restarting the BGP session.

↳ Saving Original Routing Information of Neighbors

By default, BGP does not save original routing information of neighbors.

Run the **neighbor** { *address* | *peer-group-name* } **soft-reconfiguration inbound** command to save unmodified routing information sent by a BGP peer (group).

5.3.9 Configuring the Route Attributes of BGP

BGP provides various control policies for route attributes. You can apply the policies based on actual conditions.

Working Principle

↳ AS_PATH Attribute

BGP can control distribution of routing information in three modes:

- IP address. You can run the **neighbor distribute-list** and **neighbor prefix-list** commands for implementation.
- AS_PATH attribute. See the description in this section.
- COMMUNITY attribute. See the related configuration of the COMMUNITY attribute.

You can use an AS path-based access control list (ACL) to control the distribution of routing information. Where, the AS path-based ACL uses a regular expression to parse the AS path.

Based on the standard (RFC1771), BGP does not consider the AS path length when selecting the optimum path. Generally, a shorter AS path length means a higher path priority; therefore, Nodexon considers the AS path length when selecting the optimum path. You can determine whether to consider the AS path length when selecting the optimum path based on the actual conditions.

-
- i** Within an AS, whether to consider the AS path should be consistent for all BGP speakers when the optimum path is selected; otherwise, the optimum paths selected by the BGP speakers may be different.
-

➤ MULTI_EXIT_DISC Attribute

BGP uses the MED value as the basis for comparing priorities of paths learned from EBGP peers. A smaller MED value means a higher path priority.

- By default, the MED value is compared only for paths of peers from the same AS when the optimum path is selected.
- By default, the MED value is not compared for paths of peers from other sub ASs within an AS alliance.
- By default, if a path not configured with the MED attribute is received, it is considered that the MED value of this path is 0. Since a smaller MED value means a higher path priority, this path has the highest priority.
- By default, the MED value is not compared with paths from different ASs; instead, the sequence of receiving the paths is compared.

➤ LOCAL_PREF Attribute

When sending routes received from EBGP peers to IBGP peers, a BGP speaker adds the LOCAL_PREF attribute. BGP uses the LOCAL_PREF attribute as the basis for comparing priorities of paths learned from IBGP peers. A larger value of LOCAL_PREF means a higher path priority.

You can also run the **set local-preference** command of a route map to modify the LOCAL_PREF attribute of the specified path.

➤ COMMUNITY Attribute

The COMMUNITY attribute is another mode for controlling distribution of routing information.

A community is a set of destination addresses. The COMMUNITY attribute is intended to facilitate execution of a routing policy based on a community and thereby simplify the configuration of routing information distribution control on BGP speakers. Each destination address may belong to multiple communities. An AS administrator can define the communities, to which a destination address belongs.

By default, all destination addresses belong to the Internet community and are carried in the community attribute of the path.

At present, four common community attribute values are pre-defined:

- Internet: Indicates the Internet community. All paths belong to this community.
- no-export: Indicates that the path is not advertised to EBGP peers.
- no-advertise: Indicates that the path is not advertised to any BGP peer.
- local-as: Indicates that a path is not advertised to other ASs. When an AS alliance is configured, the path is not advertised to other ASs or sub ASs.

By using the community attribute, you can control the receiving, prioritization and distribution of routing information. BGP speakers can set, add or modify the community attribute when learning, advertising or re-distributing routes. An aggregation path will contain the community attribute values of all aggregated paths.

-
- **i** BGP supports up to 32 COMMUNITY attributes for each route and allows for up to 32 COMMUNITY attributes when match and set COMMUNITY of a route map are configured.
-

➤ Others

During selection of the optimum path, if two paths with the same path attributes are received from different EBGPs, the optimum path is selected based on the receiving sequence by default. You can disable comparison of the receiving sequence but use the path with a smaller router ID as the optimum path.

Related Configuration

Configuring AS_PATH Attribute

- **ip as-path access-list** *path-list-name* { **permit** | **deny** } *as-regular-expression*

Defines an AS path list.

- **neighbor** { *address* | *peer-group-name* } **filter-list** *path-list-name* { **in** | **out** }

By default, no filtering policy is configured for BGP peers.

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on the AS path list to advertise or receive only routes that match the policies.

- **neighbor** { *address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

By default, no filtering policy is configured for BGP peers.

The configuration is the same as when receiving and sending routing information for a specified BGP peer (group). Routing policies are executed based on a route map or the set rules in the route map are used to modify routing attributes.

i In the route-map configuration mode, you can run the **match as-path** command to modify AS path attributes by using an AS path list or directly run the **set as-path** command to modify AS attribute values.

- **bgp bestpath as-path ignore**

Allows BGP not to consider the AS path length when selecting the optimum path. The AS path length is compared by default.

By default, a smaller AS path length means a higher path priority.

Configuring MULTI_EXIT_DISC Attribute

- **bgp always-compare-med**

Allows for comparing the MED values of paths from different ASs, which is disabled by default.

- **bgp bestpath med confed**

Allows for comparing the MED values of paths of peers from other sub ASs in the same AS alliance, which is disabled by default.

- **bgp bestpath med missing-as-worst**

Sets a path not configured with the MED attribute to the lowest priority, which is disabled by default.

- **bgp deterministic-med**

Allows for comparing the paths of peers within the same AS, which is disabled by default.

Configuring LOCAL_PREF Attribute

- **bgp default local-preference** *value*

Changes the default local preference value, ranging from 0 to 4,294,967,295. A larger value means a higher priority. The default value is 100.

↘ Configuring COMMUNITY Attribute

- **ip community-list standard** *community-list-name* { **permit** | **deny** } *community-number*

Creates a community list. **community-list-name** indicates the name of the community list.

i *community-number*: Indicates a value (0 to 4,294,967,295) specified by a user or a known community attribute (internet, local-AS, no-advertise or no-export).

- **neighbor** { *address* | *peer-group-name* } **send-community**

Allows for sending the community attribute to a specified BGP peer (group), which is not configured by default.

- **neighbor** { *address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

The configuration is the same as that for routing information receiving and sending for a specified BGP peer (group). Routing policies are executed based on a route map. No filtering policy is configured for peers by default.

i In the route-map configuration mode, you can run the **match community-list [exact]** and **set community-list delete** commands to modify the community attribute by using a community list or directly run the **set community** command to modify the community value.

↘ Others

- **bgp bestpath compare-routerid**

Allows BGP to compare the router ID when selecting the optimum path, which is disabled by default.

5.3.10 Configuring BGP Route Aggregation

BGP-4 supports CIDR and therefore allows for creating aggregation entries to reduce the size of a BGP routing table. BGP aggregation entries can be added to a BGP routing table only when valid paths are available within the aggregation range.

Working Principle

Aggregate one or more detailed BGP routes into a BGP route with a shorter network mask.

i By default, BGP advertises all path information before and after aggregation. If you hope that only aggregated path information is advertised, you can run the **aggregate-address summary-only** command.

i When the **aggregate-address** command is used to configure an aggregated route, the aggregated route takes effect immediately as long as there are routes in the configured address range.

Related Configuration

↘ Configuring BGP Route Aggregation

- **aggregate-address** *address mask*

Configures BGP route aggregation. By default, BGP does not create any aggregated routing entry.

- **aggregate-address** *address mask as-set*

Configures an aggregation address and stores the AS path information within the aggregation address range. By default, BGP does not store AS path information.

- **aggregate-address** *address mask summary-only*

Configures an aggregation address and advertises only an aggregated path. By default, BGP advertises all path information within the aggregation range.

- **aggregate-address** *address mask as-set summary-only*

Configures an aggregation address, stores the AS path information within the aggregation address range and advertises only aggregated paths.

5.3.11 Configuring BGP Route Dampening

If a route changes between being valid and invalid, route flapping occurs.

Route flapping often causes transmission of unstable routes in a network, and thereby causes network instability. BGP route dampening is a method for reducing route flapping. It reduces possible route flapping by monitoring routing information from EBGp peers.

Working Principle

Terms used in BGP route dampening are as follows:

- **Route Flap:** A route changes between being valid and invalid.
- **Penalty:** Once route flapping occurs, a BGP speaker enabled with route dampening adds a value to the penalty for this route. The penalty is accumulated until the Suppress Limit is reached.
- **Suppress Limit:** When the penalty of a route is greater than this value, the route will be suppressed.
- **Half-life-time:** The time used for the penalty to be halved.
- **Reuse Limit:** When the penalty value of a route is smaller than this value, route suppression will be canceled.
- **Max-suppress-time:** The longest time that a route can be suppressed.

A brief description of route dampening processing: BGP speaker punishes a route once (adds to the penalty) route flapping occurs. When the penalty reaches the Suppress Limit, the route will be suppressed. When the Half-life-time reaches, the penalty is halved. When the penalty is reduced to the Reuse Limit, the route is activated again. The Max-suppress-time indicates the longest time that the route can be suppressed.

Related Configuration

▾ [Configuring BGP Route Dampening](#)

- **bgp dampening**

Enables BGP dampening, which is disabled by default.

- **bgp dampening** *half-life-time reuse suppress max-suppress-time*

Configures the parameters of route dampening.

half-life-time (1~45minutes): The default value is 15 minutes. A larger value means a longer flapping suppression and dampening period.

reuse (1~10000): The default value is 750. A smaller value means longer time for continuous stabilization before a flapping route is enabled again.

suppress (1~20000): The default value is 2,000. A smaller value means more flapping times allowed before suppression.

max-suppress-time (1~255minutes): The default value is 4*half-life-time. A larger value means longer maximum suppression time.

▾ Displaying BGP Route Dampening

- **show ip bgp dampening flap-statistics**

Displays the flapping statistics about all routes.

- **show ip bgp dampening dampened-paths**

Displays the statistics about suppressed routes.

▾ Resetting BGP Route Dampening

- **clear ip bgp flap-statistics**

Clears the flapping statistics about all routes that are not suppressed.

- **clear ip bgp flap-statistics** *address mask*

Clears the flapping statistics about specified routes (excluding suppressed routes).

- **clear ip bgp dampening** [*address* [*mask*]]

Clears the flapping statistics about all routes, including routes whose suppression is cancelled.

5.3.12 Configuring the Management Distance of BGP

The management distance is used to evaluate the reliability of various route sources. A smaller management distance means a better route.

Working Principle

▾ Management Distance of BGP

The management distance indicates the reliability of a route source, ranging from 1 to 255. A larger value means lower reliability. BGP sets different management distances for routing information learned from different sources, including External-distance, Internal-distance and Local-distance.

- **External-distance:** Indicates the management distance of routes learned from EBGP peers.
- **Internal-distance:** Indicates the management distance of routes learned from IBGP peers.
- **Local-distance:** Indicates the management distance for routes learned from peers but it is considered that better routes can be learned from IGP. Generally, these routes can be indicated by the **Network Backdoor** command.

i You are not advised to change the management distance of BGP. If you really need to change the management distance of BGP, please remember:
The external-distance should be shorter than the management distances of other IGP routing protocols (OSPF and RIP).
The internal-distance and local-distance should be longer than the management distances of other IGP routing protocols.

↳ Backdoor Route

If you prefer an IGP route but do not use an EBGP route, you can set the EBGP route as the backdoor route. By default, the management distance for routes learned from a BGP speaker for which an EBGP connection is established is 20. You can run the **network backdoor** command to set the management distance of the network information to 200 so that the same network information learned from IGP has the highest priority. The networks learned from IGP are considered backdoor networks and are not advertised.

Related Configuration

↳ Configuring the Management Distance of BGP

You can run the **distance bgp** *external-distance internal-distance local-distance* command to configure the management distance of BGP. The value ranges from 1 to 255.

The default value of *external-distance* is 20; the default value of *internal-distance* is 200; the default value of *local-distance* is 200.

A longer management distance means a lower route priority.

↳ Configuring a Backdoor Route

Run the **network** *network-number mask network-mask* **backdoor** command to configure a backdoor route. By default, no backdoor route is configured.

5.3.13 Configuring Multi-path Load Balancing of BGP

Multi-path load balancing means that there are multiple paths to the same network and data packets are evenly forwarded by these paths. In a routing table, one route has multiple next hops.

According to the types of equivalent routes, multi-path load balancing of BGP is classified into the following types:

- **EBGP load balancing:** implement load balancing for routes learned from EBGP neighbors.
- **IBGP load balancing:** implement load balancing for routes learned from IBGP neighbors.

i Both the IPv4 and IPv6 protocol stacks support multi-path load balancing.

 Load balancing cannot be implemented between IBGP and EBGP routes (including EBGP routes in an alliance).

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. If there are optimum multiple routes with the same priorities, BGP still selects a unique route by using comparison rules, notifies the route to the forwarding plane and controls the forwarding of data streams. After multi-path load balancing is enabled, BGP calculates a unique optimum route and also lists paths with the same priorities as equivalent routes. Then, BGP notifies the optimum route and the equivalent routes to the forwarding plane to implement load balancing.

Equivalent routes have the same basic attributes and priorities. That is, according to the optimum path selection rules of BGP, the paths have the same priorities before router-IDs are compared.

AS_PATH Loose Comparison

By default, equivalent routes must have the same AS-PATH attributes. Under such strict conditions, load balancing cannot be implemented in certain environments. In this case, you are advertised to enable the AS-PATH loose comparison mode. In the AS-PATH loose comparison mode, when other conditions for equivalent routes are met, as long as the AS-PATH lengths of routes and the AS-PATH lengths of routes from an alliance are the same respectively, it is considered that the conditions for equivalent routes are met.

 When the next hops of multiple BGP equivalent paths recur to the same IGP output interface, load balancing cannot be implemented.

Related Configuration

Configuring Multi-path Load Balancing of BGP

- **maximum-paths ebgp** *number*

Enables the multi-path load balancing function of EBGP.

number indicates the number of equivalent next hops, ranging from 1 to 32. The default value is 1. A larger value means more equivalent next hops allowed.

- **maximum-paths ibgp** *number*

Enables the multi-path load balancing function of IBGP.

number indicates the number of equivalent next hops, ranging from 1 to 32. The default value is 1. A larger value means more equivalent next hops allowed.

Configuring AS_PATH Loose Comparison

- **bgp bestpath as-path multipath-relax**

Enables the BGP AS-PATH loose comparison mode.

5.3.14 Configuring BGP FRR

With high-speed development of IP technologies and application of various complex services, the requirements for network security and stability become increasingly higher. Especially, certain real-time services (audios and videos) are sensitive to network running status and may be largely affected by unstable networks. Therefore, more and more focus and importance are attached to network reliability. With these requirements, the IP FRR function comes into being. It is intended to use a backup link to maintain data forwarding during route platform convergence after a faulty link is detected, in order to achieve the ideal targets of "zero delay" and "zero loss" in packet forwarding.

BGP FRR is shorted for Fast Reroute.

Working Principle

If a BGP routing table has multiple paths to the same network, BGP calculates the route with the highest priority by default. After the BGP FRR function is used, BGP selects a backup route for each optimum route. After BFD FRR detects that the master link is faulty, it switches the data to the originally calculated backup link for forwarding. After route convergence is completed, data is switched to the optimum route re-calculated for forwarding. In this way, BGP FRR can avoid route disconnection due to a link fault before BGP route convergence is completed.

-  BGP FRR is supported only in the IPv4 Unicast and IPv4 VRF address families of BGP.
-  Only one backup route can be generated and the next hop of the backup route cannot be the same as that of the preferred route.
-  A backup next hop cannot be generated for an Equal-Cost Multi-Path Routing (ECMP) route.
-  In the BGP IPv4 VRF configuration mode, BGP FRR has a lower priority than VPN FRR. That is, if VPN FRR is enabled in the VRF mode, BGP FRR takes effect only when VPN FRR fails to calculate a backup route.

Related Configuration

Configuring BGP FRR

Run the **bgp fast-reroute** command to enable the BGP FRR function, which is disabled by default.

Configuring a BFD Session to a BGP Neighbor

Run the **neighbor peer-address fall-over bfd** command to configure a BFD session to a BGP neighbor, which is not configured by default.

5.3.15 Configuring BGP Timers

You can manually configure various timers within BGP to meet the neighbor keepalive and route management requirements in different network environments.

Working Principle

BGP Neighbor Keepalive Timer

BGP uses the Keepalive timer to maintain a valid connection with a peer and uses the Holdtime timer to identify whether a peer is valid. By default, the value of the Keepalive timer is 60 seconds and the value of the Holdtime timer is 180 seconds. When a BGP connection is established between two BGP speakers, the two BGP speakers negotiate about the Holdtime timer value and select a smaller value. 1/3 of the negotiated Holdtime timer value and the configured Keepalive timer value are compared and the smaller value is used as the Keepalive timer value.

↘ Neighbor Reconnection Timer

To reduce the impacts of frequent BGP reconnection to a neighbor on the network bandwidth, after a BGP speaker detects failure of a neighbor connection, the BGP speaker attempts to reconnect the neighbor after the connect-retry timer expires. By default, the value of the connect-retry timer is 15s.

↘ Route Advertisement Timer

To reduce the impacts of route update packets on the network bandwidth, after a BGP speaker detects a network topology change, the BGP speaker does not advertise the route update to its neighbors immediately. Instead, the BGP speaker uses a regular update mechanism to advertise all changed routing information to its neighbors.

Related Configuration

↘ Configuring the BGP Neighbor Keepalive Timer

- **timers bgp** *keepalive holdtime*

Adjusts the BGP *keepalive* and *holdtime* values for all peers.

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

- **neighbor** { *address* | *peer-group-name* } **timers** *keepalive holdtime*

Configures the *keepalive* and *holdtime* values used for connecting to a specified BGP peer (group).

The *keepalive* value ranges from 0 to 65,535. The default value is 60 seconds.

The *holdtime* value ranges from 0 to 65,535. The default value is 180 seconds.

↘ Configuring the Neighbor Re-connection Timer

- **neighbor** { *address* | *peer-group-name* } **timers connect** *connect-retry*

Configures the *connect-retry* value used for reconnecting to a specified BGP peer (group).

The value of *connect-retry* ranges from 1 to 65,535. The default value is 15 seconds.

↘ Configuring the Route Advertisement Timer

- **neighbor** { *address* | *peer-group-name* } **advertisemet-interval** *seconds*

Configures the minimum interval for sending route updates to a specified BGP peer (group). The value of *advertisemet-interval* ranges from 0 to 600 seconds. The default value for IBGP peers is 0 seconds and the default value for EBGp peers is 30 seconds.

- **neighbor** { *address* | *peer-group-name* } **as-origination-interval** *seconds*

Configures the minimum interval for sending local initial route updates to a specified BGP peer (group). The value of `As-origination-interval` ranges from 1 to 65,535. The default value is 1 second.

5.3.16 Configuring BGP Route Update Mechanisms

Working Principle

BGP provides two route update mechanisms: regular-scanning update and event-triggering update. Regular-scanning update indicates that BGP uses an internal timer to start scanning regularly and update the routing table. Event-triggering update indicates that BGP starts scanning and updates the routing table when the BGP configuration commands are changed due to user configuration or the next hop of a BGP route changes.

- ❗ This function is configured based on address families and can be configured in the IPv4, IPv6, VPNv4, VPNv6, IPv4 vrf and IPv6 VRF address family modes.
- ❗ If you set the BGP route update mechanism to event-triggering update (by running the **bgp scan-rib disable** command), you must disable synchronization (by running the **no synchronization** command) and enable the BGP next-hop triggering update function (by running the **bgp nexthop trigger enable** command). On the other hand, if you enable synchronization or disable the BGP next-hop triggering update function, the BGP routing table must be updated in the regular scanning mode.

Related Configuration

↳ Configuring Route Update Mechanisms

- **bgp scan-rib disable**

Sets the BGP route update mechanism to event-triggering update. Regular-scanning update is used by default.

- **bgp scan-time** *scan-time*

Configures the regular update interval of BGP. The value of *scan-time* ranges from 5 to 60 seconds. The default value is 60 seconds.

5.3.17 Configuring the Next-Hop Triggering Update Function of BGP

The next-hop triggering update function of BGP is a method for reducing the BGP convergence time. This function is used to optimize the method for monitoring the next hop of a route to ensure that BGP can increase the BGP route convergence speed when the network topology is stable.

Working Principle

When BGP connects to a neighbor, BGP automatically monitors the next hop of the BGP route learned from the neighbor. When the next hop changes in the core routing table, BGP receives an advertisement about the next hop change and updates the BGP routing table. This optimization measure improves the BGP route convergence performance by reducing the time for detecting next-hop changes.

If this function is disabled, BGP next hop update will be discovered through regular scanning specified by scan-timer.

-  This function is configured based on address families and can be configured in the IPv4, IPv6, VPNv4, and IPv4 vrf address family modes.
-  **bgp nexthop trigger delay** and **bgp scan-time** control the same timer. When bgp scan is enabled (it is enabled by default and can be disabled by the **bgp scan-rib disable** command), if the value of **bgp nexthop trigger delay** is larger than 60s, bgp scan does not take effect because the scan timer is always triggered before the delay.
-  If the network environment is unstable (with frequent next-hop changes), especially with many routes, this function performs unnecessary route calculations, which consumes more CPU resources. Therefore, you are advised to disable this function in this environment.

Related Configuration

Configuring the Next-Hop Triggering Update Function of BGP

- **bgp nexthop trigger enable**
Enables the BGP next-hop triggering function, which is enabled by default.
- **bgp nexthop trigger delay** *delay-time*
Configures the delay of BGP next-hop triggering update. The value of *delay-time* ranges from 0 to 100 seconds. The default value is 5 seconds.

5.3.18 Configuring BGP LOCAL AS

The Local AS function of BGP is used to configure a local AS different from a router BGP AS for a specific peer. This is similar to deploying a new virtual AS between the peer devices. When the local router BGP AS changes, you can establish a BGP connection without changing the BGP configurations on the peer device. This function is mainly used for AS migration and merging of large networks and ensures that the device configurations in other interconnected ASs are not affected.

Working Principle

In BGP, when a local device connects to a peer, the local device advertises the local AS number to the peer by using an Open message. The peer checks whether the BGP AS number advertised is the same as the local AS number. If the AS numbers are different, the peer will deny the BGP connection. By default, the local AS in the BGP connection is a route BGP AS. However, if a local AS is configured for the peer, the configured local AS will replace the route BGP AS when a BGP connection is established between the local device and the peer.

-  The **neighbor peer-address local-as as-num** command for configuring the BGP Local AS function can be followed by more options. For details, see the Command Reference.
-  The BGP Local AS function is applied only to EBGP peers, but is not applied to IBGP peers and alliance EBGP peers. In addition, the BGP Local AS function has the following restrictions:
 - 1) The configured local AS cannot be the same as the remote AS of a peer.
 - 2) The local AS cannot be configured independently for a member of a peer group.
 - 3) The configured local AS cannot be the same as the route BGP AS.
 - 4) If a device is a member of an AS alliance, the local AS cannot be the same as the AS alliance number.

Related Configuration

Configuring BGP LOCAL AS

- **neighbor** { *address* | *peer-group-name* } **local-as** *as-number*

Configures a local AS for a peer. By default, no local AS is configured for any peer. The local AS of a peer is the route BGP AS.

5.3.19 Configuring BGP Capacity Protection

There are often a large number of BGP routes, which may cause overload of a device, especially for a device with small memory. Protecting BGP capacity helps avoid non-predictable running status caused by consumption of device capacity.

Working Principle

Restricting the Number of BGP Routes

Restrict the number of BGP routes by setting the maximum number of routes in a BGP address family and the maximum number of routes that can be learned by a BGP neighbor.

Entering the OVERFLOW State in case of Insufficient Memory

If the memory is insufficient, BGP can enter the OVERFLOW state. In the OVERFLOW state, BGP generates a default route pointing to a NULL interface. If a newly learned route is not a refined route other than the default route in the current routing table, the route is discarded. In other words, general newly learned routes are discarded to ensure that the system memory is stable. The purpose of not discarding all routes is to avoid route loops in the entire network. Therefore, it is safe for BGP to enter the OVERFLOW state. BGP is allowed to enter the OVERFLOW state by default.

- ❗ By default, BGP enters the OVERFLOW state in case of insufficient memory. If you do not want BGP to enter the OVERFLOW state, you can run the **no overflow memory-lack** command to disable this function.
- ❗ In the OVERFLOW state, BGP supports only the **clear bgp** { *addressfamily* | **all** } * command at present. You can also exit from the OVERFLOW state by disabling and enabling BGP again. When the memory becomes sufficient again, BGP can also automatically exit from the OVERFLOW state.

Related Configuration

Restricting the Number of BGP Routes

- **neighbor** { *address* | *peer-group-name* } **maximum-prefix** *maximum* [**threshold**] [**warning-only**]

Restricts the maximum number of routes that can be learned from a BGP neighbor, which is not restricted by default.

- **maximum-prefix** *maximum*

Restricts the maximum number of routes in a BGP address family. The default maximum number of routes for the BGP IPv4 VRF, IPv6 VRF and IPv4 MDT address families are 10,000 and is not configured for other address families.

Configuring BGP OVERFLOW

- **overflow memory-lack**

Enable BGP to enter the OVERFLOW state in case of insufficient memory, which is enabled by default.

5.3.20 Configuring BGP GR

Graceful Restart (GR) is intended to implement uninterrupted data forwarding during restart of BGP. During active/standby switching of the management boards, the GR function keeps the network topology stable, maintains the forwarding table and ensures that key services are not interrupted.

Working Principle

-
- **i** Comply with RFC4724: Graceful Restart Mechanism for BGP. [BGP GR] is used in the following description to indicate the RFC.
-

BGP GR is not an independent process, but is jointly completed by the Restarter and Helper.

- The Restarter performs restart and maintains the working capability of the route forwarding plane when the route control plane is faulty.
- The Helper is the BGP neighbor of the Restarter and helps the Restarter to complete GR.

A capability indicating GR is added to the OPEN message of BGP, which is called "Graceful Restart Capability". This capability is used by BGP to tell its neighbor it supports the graceful restart capability. During initialization of a BGP connection, two neighbors negotiate about the GR capability.

The route update end flag (End-of-RIB, shorted as EOR) is added to the Update packet of BGP, which indicates that the routing information update to the neighbor is completed.

Figure 5-3 BGP GR Interaction Process

5. ① When BGP establishes neighborhood at the beginning, BGP uses the GR capability field in the OPEN message to negotiate about the GR capabilities of the two neighbors.
6. ② At a moment, the Restarter starts restart, and the BGP session is disconnected. The Helper detects the disconnection, keeps the route of the Restarter valid but adds the "Stale (aged but not updated)" flag to the route.
7. ③ and ④ The Restarter completes restart and connects to the Helper again.
8. ⑤ The Restarter waits for the route update message and EOR flag from the Helper.
9. ⑥ After receiving the EOR flag from all neighbors, the Restarter performs route calculation, update routing entries and then sends updated routes to the Helper.
10. ⑦ After receiving the updated routes, the Helper cancels the "Stale" flag of the routes. After receiving the EOR flag from the Restarter, the Helper deletes routes with the "Stale" flag (these routes are not updated), performs route calculation, and updates the routing entries. The entire GR process is completed.

BGP GR defines several extended and important timers:

- **Restart-Timer:** The GR Restarter advertises the time value to the GR Helper, which indicates the maximum waiting time that the GR Restarter hopes the Helper to wait before a new connection is established between them. You can run the **bgp graceful-restart restart-time** command to modify the time value.
- **Wait-For-EOR Timer:** Indicates the maximum time that the GR Restarter waits for the EOR flag from all GR Helpers. After receiving the EOR flag from all GR Helpers or after the Wait-For-EOR timer expires, the GR Restarter calculates the preferred route and updates the routing entries. You can run the **bgp update-delay** command to modify the time value.
- **StalePath Timer:** Indicates the maximum time that the GR-Helper waits for the EOR flag from the GR Restarter after a new connection is established between them. Within this period, the Helper keeps the original route of the Restarter valid. After receiving the EOR flag or after the StalePath timer expires, the Helper clears the routing entries still with the "Stale" tag. You can run the **bgp graceful-restart stalepath-time** command to modify the time value.

Related Configuration

↳ Configuring BGP GR

- **bgp graceful-restart**

Enables the Restarter capability, which is enabled by default.

- **bgp graceful-restart restart-time** *time*

Sets the Restart Timer. The default value is 120 seconds.

- **bgp update-delay** *delay*

Sets the Wait-For-EOR Timer. The default value is 120 seconds.

- **bgp graceful-restart stalepath-time** *time*

Sets the StalePath Timer. The default value is 360 seconds.

- **bgp graceful-restart disable**

Disables the address family GR capability. The address family GR capability is enabled by default. After the global BGP GR is enabled, the GR capability is automatically enabled for all address families.

i When BGP GR is implemented, all BGP peers must enable the BGP GR capability. If certain peers do not support or enable GR, BGP GR may fail to be implemented. GR failure may cause a short route black-hole or route loop, which may affect the network. Therefore, you are advised to verify that all neighbors are enabled with the BGP GR capability. You can run the **show ip bgp neighbors** command to display the capabilities successfully negotiated between BGP peers and verify that the GR capability negotiation is successful. In the BGP route configuration mode, run the **bgp graceful-restart** command to enable the BGP GR capability.

i The **bgp graceful-restart** command will not be applied to a successfully established BGP connection immediately. That is, when the BGP connection is in the Established state, the BGP peers will not re-negotiate about the GR capability immediately. To enable the BGP peers of the BGP connection to negotiate about the GR capability immediately, you need to forcibly restart the BGP peers to re-negotiate about the GR capability by running the **clear ip**

bgp 192.168.195.64 command (for example). To make GR enabling or disabling take effect immediately, you must restart the neighborhood for capability negotiation, which may cause network flapping and affect normal use of users. Therefore, you can explicitly control whether to restart the neighborhood.

- i** Supporting BGP GR does not mean that a device can be used as the Restarter to implement BGP GR. Whether to implement BGP GR also depends on the hardware capabilities of the device. Nodexon devices must support the dual-engine hot backup when being used as the GR Restarter.
- i** The restart period configured by the **bgp graceful-restart restart-time** command should not be longer than the Hold Time of the BGP peers; otherwise, the Hold Time will be used as the restart time to be advertised to the BGP peers during GR capability negotiation.
- i** The **bgp graceful-restart disable** command is used to disable the GR capability in an address family in the address family configuration mode, which is not configured by default.

5.3.21 Configuring 4-Byte AS Numbers of BGP

A traditional AS number consists of 2 bytes, ranging from 1 to 65,535. A newly defined AS number consists of 4 bytes, ranging from 1 to 4,294,967,295. Newly defined AS numbers are used to cope with exhaustion of AS number resources.

Working Principle

4-byte AS numbers support two expression modes: the decimal mode and dot mode. The decimal mode is the same as the original expression mode, that is, expressing the 4 bytes of an AS number as decimal digits. The dot mode is expressed as ([higher 2 bytes.]lower 2 bytes). If the higher 2 bytes are 0, they will not be displayed.

For example, an AS number is 65534 in the decimal mode and is 65,534 in the dot mode (the 0 at the beginning is not displayed).

For example, an AS number is 65,536 in the decimal mode, and is 1.0 in the dot mode.

For example, an AS number is 65,538 in the decimal mode, and is 1.2 in the dot mode.

-
- i** Related protocols are as follows: RFC 4893 and RFC 5396.

Configuring the Display Mode of a 4-Byte AS Number

A 4-byte AS number is displayed in the decimal mode by default. You can manually set the display mode to the dot mode. After the setting, a regular expression will use the dot mode for matching 4-byte AS numbers.

Compatibility with Devices Supporting Only 2-Byte AS Numbers

With introduction of 4-byte AS numbers, BGP connections may be established between old BGP speakers supporting only 2-byte AS numbers and new BGP speakers supporting 4-byte AS numbers. If the AS where a new BGP speaker resides has a 4-byte AS number, when an old BGP speaker creates neighborhood with the new BGP speaker, the old BGP speaker uses the reserved AS number 23,456 to replace the 4-byte AS number of the new BGP speaker. In the OPEN packets sent by the new BGP speaker to the old BGP speaker, the 4-byte AS number in the **My Autonomous System** field will be replaced by 23,456. In addition, in UPDATE packets sent to the old BGP speaker, the 4-byte AS number in the AS-PATH and AGGREGATOR attributes will also be replaced by 23,456. In addition, new optional transfer attributes AS4-PATH and AS4-

AGGREGATOR will be used to record the real 4-byte AS number so that the real AS-PATH and AGGREGATOR attributes can be restored when the route reaches a next new BGP speaker.

In other cases, the real AS number of the remote end is used to create neighborship.

Related Configuration

↘ Configuring the Display Mode of a 4-Byte AS Number

- **bgp asnotation dot**

Displays a 4-byte AS number in the dot mode. The decimal mode is used by default.

5.3.22 Configuring a Regular Expression

A regular expression is a formula that matches strings based on a template.

The formula is used to assess text data and return True or False to indicate whether the expression can correctly describe the data.

Working Principle

Regular expressions are used in BGP path attributes. The following table describes the usages of special characters in a regular expression.

Character	Symbol	Special Meaning
Period	.	Matches any single character.
Asterisk	*	Matches zero or any sequence in a string.
Plus sign	+	Matches one or any sequence in a string.
Question mark	?	Matches zero or one symbol in a string.
Caret	^	Matches the start of a string.
Dollar sign	\$	Matches the end of a string.
Underline	_	Matches the start, end and space of commas, brackets and strings.
Square brackets	[]	Matches a single character within a range.

Related Configuration

↘ Using a Regular Expression in a show Command

- **show ip bgp regexp *regexp***

Displays the BGP routing information in a specified regular expression matched by the AS-PATH attribute.

- **show ip bgp quote-regexp *regexp***

Displays the BGP routing information in a regular expression within the specified double quotation marks matched by the AS-PATH attribute.

5.3.23 Configuring BGP Session Retention

By default, when an UPDATE packet is received from a neighbor, a BGP session will be disconnected if an error is detected on the multi-protocol routing attribute. This will cause flapping of the routes in all address families of this neighbor. That is, the routing error in an address family will affect the route stability in other address families.

Working Principle

After the BGP session retention function is enabled, if an error occurs in the routing attribute of an address family, only the routing information in this address family related to the neighbor is deleted. In addition, the BGP session and other address families are not affected, which enhances the stability of BGP.

recovery-time is used to configure the time for waiting for automatic route recovery, which requires that a neighbor should support the route-refresh capability. After the recovery-time, BGP sends the route-refresh message of the address family to the neighbor and re-advertises all routing information in the address family to this neighbor.

 In the session retention state, you can manually reset the neighbor to exit from the session retention state.

Related Configuration

Configuring BGP Session Retention

- **bgp mp-error-handle session-retain [recovery-time time]**

Enables the BGP session retention function, which is disabled by default.

recovery-time time configures the time for waiting for automatic route recovery, ranging from 10 to 4,294,967,296 seconds. The default value is 120.

5.3.24 Configuring BGP Delayed Advertisement upon System Restart

By default, after the neighborhood is established after system restart, a BGP peer can advertise route information to its neighbors. This is normal in most cases. However, in certain cases, for example, there are many neighbors or routes during startup but writing entries into the hardware is slow. In this case, the neighbors have learned the routes and started forwarding traffic, but the hardware has not completed writing of entries at the local end, which causes failure of traffic forwarding.

Working Principle

The BGP delayed advertisement upon system restart ensures that routes are not advertised to neighbors immediately after the neighborhood is established upon system restart and that the routes are advertised after a period. This function has no effect on other behaviors such as route receiving performed by the neighbors. If part of the routes is not affected by the delay, configure prefix-list policy to match this part of routes so that route advertisement can be more flexible.

delay-time is used to configure the waiting time before routes are advertised to the neighbors. **startup-time** is used to configure the startup time. Within the startup-time, BGP sends routing information to the neighbors at the interval specified by **delay-time**.

 After the startup-time ends, the default route advertisement behavior recovers.

Related Configuration

↳ Configuring BGP Delayed Advertisement upon System Restart

- **bgp initial-advertise-delay** *delay-time* [*startup-time*] [**wait-for-controller**]

Enables BGP delayed advertisement upon system restart, which is disabled by default.

delay-time configures the delay time for advertising routes after the BGP neighborhood is established upon system restart, ranging from 1 to 600 seconds. The default value is 1s.

startup-time configures the time range for system restart, ranging from 5 to 58,400 seconds. The delayed route advertisement mechanism is used within this range. The default value is 600s.

Configure the **wait-for-controller** command to ensure that routes are advertised only after the controller delivers configuration messages and receives EOR messages from the neighbors. If no EOR message is received within the time specified by *startup-time*, routes will be advertised forcibly.

- **bgp initial-advertise-delay prefix-list** *prefix-list-name*

By default, the BGP delayed advertisement upon system restart is disabled. If enable it, the route will be immediately sent after the prefix-list policy is matched.

prefix-list-name: indicates the name of prefix-list policy.

5.3.25 Configuring BGP Delayed Advertisement for First Routes

By default, after the neighborhood is established, a BGP peer can advertise route information to its neighbors. However, neighbors with the neighborhood newly established will send out the route information after a delayed period of time.

Working Principle

After BGP starts, BGP peers negotiate to establish the neighborhood before sending route information (update packets). An optimum route is calculated on the local end and sent to the peer end. By default, routes are advertised directly. After a neighbor receives a better route, it updates the route information to the peer. As a result, extra route advertisement occurs. **update-delay** can be configured to shorten the route information update time.

In addition, after **update-delay** is configured on the local end, a specific neighbor sends route information to the local end, the local end selects an optimum route, and then sends out the route information immediately to other neighbors by default. In this case, extra advertisement also occurs. Therefore, the value of **update-delay** includes two parts: delay of route advertisement from the local end to a specific neighbor and delay of route advertisement from the local end to other neighbors after the specific neighbor advertises the route information to the local end.

- ❗ If BGP delayed advertisement upon system restart and BGP delayed advertisement for first routes are enabled at the same time, BGP delayed advertisement upon system restart takes precedence over BGP delayed advertisement for first routes.
- ❗ BGP GR is not affected by either BGP delayed advertisement upon system restart or BGP delayed advertisement for first routes, that is, the BGP GR route advertisement is not affected by the delay time.

Related Configuration

↘ Creating a BGP Neighbor

By default, no neighbor is specified on a BGP speaker. You need to manually configure a BGP neighbor.

Run the **neighbor** { *peer-address* | *peer-group-name* } **remote-as** *as-number* command to manually create a BGP neighbor and specify the AS number of the neighbor.

↘ Configuring BGP Delayed Advertisement for First Routes

By default, BGP delayed advertisement for first routes is disabled for neighbors.

Run the **neighbor** { *peer-address* | *peer-group-name* } **update-delay** *delay-time* command to enable BGP delayed advertisement for first routes.

5.3.26 Other Related Configurations

- i For configuration and application of BGP MCE, see section "VRF Configuration Guide".
- i For configuration and application of BGP/MPLS VPN, see section "BGP/MPLS VPN Configuration Guide".

5.4 Configuration

Configuration	Description and Command	
Configuring a BGP Peer (Group)	(Mandatory) It is used to create a BGP neighbor.	
	router bgp	Enables BGP.
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.
Configuring MD5 Authentication	(Optional) It is used to perform encrypted authentication for the BGP neighbor.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>	Configures the password for encryption.
Configuring a Route Reflector	(Optional) It is used to reduce the number of BGP neighbor connections.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client	Specifies a peer (group) as a reflector client.
Configuring an AS Alliance	(Optional) It is used to reduce the number of BGP neighbor connections.	
	bgp confederation identifier <i>as-number</i>	Configures the BGP alliance ID.
	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]	Configures a BGP alliance neighbor.
Configuring Multi-path Load Balancing of BGP	(Optional) It is used to implement multi-path load balancing.	
	maximum-paths ibgp <i>number</i>	Configures IBGP load balancing.
	maximum-paths ebgp <i>number</i>	Configures EBGP load balancing.
	bgp bestpath as-path multipath-relax	Enables the BGP AS-PATH loose comparison mode.
Configuring EBGP FRR	(Optional) It is used to increase the convergence speed when a network fault occurs.	
	bgp fast-reroute	Configures BGP FRR.

Configuration	Description and Command	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } fall-over bfd	Configures a BFD session to a BGP neighbor.
Configuring FRR in an IBGP Route Reflection Environment	(Optional) It is used to increase the convergence speed when a network fault occurs.	
	bgp fast-reroute	Configures BGP FRR.
Configuring Local ASs	(Optional) It is used for transitional deployment during network migration.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [dual-as]]]	Configures the local AS for a BGP neighbor.
Configuring BGP GR	(Recommended) It is used to improve the network reliability.	
	bgp graceful-restart	Enables the BGP GR capability.
	bgp graceful-restart restart-time <i>restart-time</i>	Configures the maximum time for BGP GR.
	bgp graceful-restart stalepath-time <i>time</i>	Configures the maximum retention time for BGP stable route.
Configuring a BGP IPv6 Address Family	(Optional) It is used to deploy an IPv6 network by using BGP.	
	address-family ipv6 unicast	Enters the BGP IPv6 unicast configuration mode.
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate	Activates the address family capability of a BGP neighbor in the current configuration mode.
Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers	Optional. It is used for interconnecting with an old device that supports only 2-byte AS numbers.	
	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>	Creates a BGP neighbor.

5.4.1 Configuring a BGP Peer (Group)

Configuration Effect

- Configure BGP and create IBGP and EBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **ebgp-multihop** parameter for the neighbor.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring a Source Interface for a BGP Neighbor

- (Optional) Perform this configuration in the BGP configuration mode. By default, BGP automatically selects a local interface that reaches the destination IP address of a peer as the source interface.

i For an IBGP neighbor, you are advised to use a Loopback interface as the source interface.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Creating a Source Interface for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } update-source { <i>interface-type interface-number</i> <i>address</i> }
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>interface-type interface-number</i> : Indicates an interface name. <i>address</i> : Directly specifies the network interface address used for creating a BGP connection.
Command Mode	BGP configuration mode
Usage Guide	The source interface of a neighbor must be a local valid interface or address.

Configuration Example

Configuring a BGP Peer (Group)

<p>Scenario Figure 5-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-4. ● Configure a loopback interface on A, B, and C and create an IBGP neighbor based on the loopback interface. ● Create an EBGP neighborhood by using the directly connected interfaces on C and D. ● Create an IBGP peer group on C.
<p>A</p>	<pre>A# configure terminal A(config)# interface loopback 0 A(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255 A(config-if-Loopback 0)# exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# router bgp 65536 A(config-router)# neighbor 10.1.1.3 remote-as 65536 A(config-router)# neighbor 10.1.1.3 update-source loopback 0</pre>

```

Common Errors

- IGP is not enabled and the interconnection between the local loopback address and the loopback address on the IBGP neighbor fails, which causes that the neighbor fails to be created.
- `ebgp-multihop` is not configured when an EBGP is not directly connected, which causes that a TCP connection fails to be created.

5.4.2 Configuring MD5 Authentication

Configuration Effect

- Configure MD5 for encrypted authentication between EBGP and IBGP neighbors.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.
- If an EBGP neighbor is not directly connected, you need to configure the **`ebgp-multihop`** parameter for the neighbor.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring an MD5 Password for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } password [0 7] <i>string</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. 0 : Displays a password not encrypted. 7 : Displays a password encrypted. <i>string</i> : Indicates a password for TCP MD5 authentication, consisting of a maximum of 80 characters.
Command Mode	BGP configuration mode
Usage Guide	The same passwords must be configured on the two ends of a BGP neighborhood.

Configuration Example

↘ Configuring BGP MD5 Authentication

<p>Scenario Figure 5-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-5. ● Configure a loopback interface on B and C and create an IBGP neighbor based on the loopback interface. ● Create an EBGP neighborship by using the directly connected interfaces on A and B. ● Configure the passwords on A, B and C for their neighbors.
<p>A</p>	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# exit A(config)# router bgp 65537 A(config-router)# neighbor 192.168.1.2 remote-as 65536 A(config-router)# neighbor 192.168.1.2 password 7 ebgpneighbor</pre>

Common Errors

- The passwords for MD5 encrypted authentication at the two ends of a BGP neighborhood are different.

5.4.3 Configuring a Route Reflector

Configuration Effect

- Configure a route reflector in the IBGP environment to reduce the number of BGP neighbor connections.

Notes

- If an IBGP neighbor is not directly connected, you need to configure IGP or a static routing protocol to implement interconnection.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Creating a BGP Reflector

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↳ Creating a BGP Reflector

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } route-reflector-client
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.

Command Mode	BGP configuration mode
Usage Guide	-

Configuration Example

Configuring a BGP Route Reflector

<p>Scenario Figure 5-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-6. ● Configure a loopback interface on all devices and create an IBGP neighborship by using the loopback interface according to the connection lines as shown in Figure 5-6. ● Configure route reflection on the device RR and specify A, B, C and D as reflector clients.

5.4.4 Configuring an AS Alliance

Configuration Effect

- Configure a BGP alliance to reduce the number of BGP neighbor connections.

Notes

- It is advised to use private AS numbers for sub ASs (also called member ASs) within an alliance. Private AS numbers range from 64,512 to 65,535.
- Within a sub AS of an alliance, full mesh must be established for all BGP speakers (route reflectors can be further configured within the sub AS).
- An EBGP neighborhood must be established between sub ASs of an alliance.
- All BGP speakers within an alliance must belong to a sub AS within the alliance.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Configuring a BGP Alliance ID

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring a BGP Alliance Member

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring Multiple Hops for an EBGP Neighbor

- Perform this configuration in the BGP configuration mode. It is mandatory when an EBGP neighbor is not directly connected.

↘ Configuring BGP Route Re-distribution to a Network

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when a local route needs to be advertised. You can also configure an alternative network by means of re-distribution.

Verification

- Run the **show** command to display the BGP neighbor status.
- Run the **show** command to display the BGP routing table information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Enabling a BGP Alliance ID

Command	bgp confederation identifier <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring a BGP Alliance Member

Command	bgp confederation peers <i>as-number</i> [... <i>as-number</i>]
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	BGP configuration mode
Usage Guide	All member ASs of a local EBGP alliance must be identified.

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.

	<i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ **Configuring Multiple Hops for an EBGP Neighbor**

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } ebgp-multihop [<i>ttl</i>]
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>ttl</i> : Indicates the maximum number of hops that are allowed, ranging from 1 to 255.
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ **Configuring BGP Route Re-distribution to a Network**

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network address. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP configuration mode
Usage Guide	The core routing table must contain same IGP (or static and directly connected) routes.

Configuration Example

➤ **Configuring a BGP Alliance**

Scenario Figure 5-7	
Configuration	<ul style="list-style-type: none"> Configure BGP on A and B, set the AS number to 65,536 and configure an IBGP neighborship.

Steps	<ul style="list-style-type: none"> ● Configure BGP on C and D, set the AS number to 65,537 and configure an IBGP neighborship. ● Configure BGP on ASBR1 and E, set the AS number to 65,538 and configure an IBGP neighborship. ● Configure an alliance ID 100 on A, B, C, D, E and ASBR1. ● Configure the alliance member 65,537 on A, configure C as an EBGP neighbor, and set the peer AS number to 65,537. ● Configure the alliance members 65,536 and 65,538 on C, configure A as an EBGP neighbor and set the peer AS number to 65,536, configure ASBR1 as an EBGP neighbor and set the peer AS number to 65,538. ● Configure the alliance members 65,537 on ASBR1, configure C as an EBGP neighbor and set the peer AS number to 65,537, configure ASBR2 as an EBGP neighbor and set the peer AS number to 200. ● Configure BGP on ASBR2 and set the AS number to 200; configure ASBR1 as an EBGP neighbor and set the peer AS number to 100.

Common Errors

- No BGP alliance neighbor is configured.
- Full mesh is not established within sub ASs of an alliance.

5.4.5 Configuring Multi-path Load Balancing of BGP

Configuration Effect

- Implement multi-path load balancing for IBGP routes.
- Support AS-PATH loose comparison.

Notes

- Routes learned from an IBGP neighbor must have the same priority (the router-ID does not need to be compared).

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring BGP Load Balancing

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring AS-PATH Loose Comparison

- (Optional) Perform this configuration in the BGP configuration mode. Perform this configuration when load balancing needs to be implemented for routes learned from different ASs.

Verification

- Run the **show** command to display BGP routing information.
- Run the **show** command to display the core routing table information.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address.

Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ [Configuring BGP Load Balancing](#)

Command	maximum-paths ibgp <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of equivalent paths, ranging from 1 to 32. If the value is 1, multi-path load balancing of IBGP will be disabled.
Command Mode	BGP configuration mode
Usage Guide	-

↘ [Configuring AS-PATH Loose Comparison](#)

Command	bgp bestpath as-path multipath-relax
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

[Configuration Example](#)

↘ [Configuring Multi-path Load Balancing of IBGP](#)

Scenario
Figure 5-8

Configuration Steps

- Enable BGP on all devices and set the AS numbers as shown in Figure 5-8.
- Establish IBGP neighborships between A and B and between A and C by using directly connected interfaces.
- Establish EBGP neighborships between B and D and between C and E by using directly connected interfaces.
- Re-distribute the same routes to D and E.
- Configure IBGP load balancing on A and enable the AS-PATH loose comparison mode.

```

Common Errors

- The priorities of multi-hop BGP routes are different, which causes load balancing failure.

5.4.6 Configuring EBGPFRR

Configuration Effect

- Implement EBGPFRR.

Notes

- (Optional) Configure a neighbor BFD session to implement fast link fault detection.

Configuration Steps

▾ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

▾ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

▾ Configuring BGP FRR

- (Mandatory) Perform this configuration in the BGP configuration mode.

▾ Configuring a Neighbor BFD Session

- (Optional) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display routing information.

Common Errors

- No BFD session is configured for BGP neighbors.

5.4.7 Configuring Local ASs

Configuration Effect

- Smoothly migrate the network configurations of router A from AS 23 to AS 3600.

Notes

N/A

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the Local AS for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the information.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring the Local AS for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } local-as <i>as-number</i> [no-prepend [replace-as [dual-as]]]
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates a local AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode. no-prepend : Does not add the local AS to the AS-PATH in the routing information received by a peer. This option is not available by default. replace-as : For the AS-PATH in the routing information sent by a peer, the local AS is used to replace the BGP AS. This option is not available by default. dual-as : Enables a peer to use the BGP AS or Local AS to establish a BGP connection with a device. This option is not available by default.
Command	BGP configuration mode

Mode

Sent 0 messages, 0 notifications, 0 in queue
```

5.4.8 Configuring BGP GR

Configuration Effect

- Configure BGP GR to implement network deployment with high reliability.

Notes

- To successfully deploy the BGP GR function, you need to use a neighbor device as the GR Helper.
- In an BGP environment, you also need to configure IGP GR.
- After BGP GR is enabled, you need to reset a BGP neighbor connection to make it take effect.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Configuring BGP GR

- Perform this configuration in the BGP configuration mode, which is configured by default.

↘ Configuring a BGP GR Timer

- (Optional) Perform this configuration in the BGP configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↘ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring BGP GR

Command	bgp graceful-restart
Parameter Description	-
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring the BGP GR Restart Timer

Command	bgp graceful-restart restart-time <i>restart-time</i>
Parameter Description	<i>restart-time</i> : Indicates the maximum waiting time that the GR Restarter hopes the GR Helper to wait before a new connection is created, ranging from 1 to 3600 seconds.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring the BGP GR Route Stale Timer

Command	bgp graceful-restart stalepath-time <i>time</i>
Parameter Description	<i>time</i> : Indicates the maximum time that a stale route keeps valid after the connection with a neighbor GR device is recovered, ranging from 1 to 3600 seconds.
Command Mode	BGP configuration mode
Usage Guide	-

↘ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer

end.

Configuration Example

Configuring BGP GR

<p>Scenario Figure 5-11</p>	<p>The diagram illustrates two Autonomous Systems (AS). AS 200 consists of a single router R1. AS 100 consists of three routers: R2, R3, and R4. R1 is connected to R2 via a solid line, representing an EBGP neighborship. R2, R3, and R4 are interconnected with each other via dashed lines, representing an IBGP neighborship. A legend indicates that solid lines represent EBGP and dashed lines represent IBGP.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-11. ● Configure a loopback interface on R2, R3, and R4 and create an IBGP neighborship based on the loopback interface. ● Create an EBGP neighborship by using the directly connected interfaces on R1 and R2. ● Enable BGP GR on R1, R2, R3, and R4.
<p>R1</p>	<pre>R1# configure terminal R1(config-router)# exit R1(config)# router bgp 100 R1(config-router)# bgp graceful-restart</pre>
<p>R2</p>	<pre>R2# configure terminal R2(config)# router ospf 1 R2(config-router)# graceful-restart R2(config-router)# exit R2(config)# router bgp 100 R2(config-router)# bgp graceful-restart</pre>
<p>R3</p>	<pre>R3# configure terminal</pre>

	<pre>R3(config)# router ospf 1 R3(config-router)# graceful-restart R3(config-router)# exit R3(config)# router bgp 100 R3(config-router)# bgp graceful-restart</pre>
<p>R4</p>	<pre>R4# configure terminal R4(config)# router ospf 1 R4(config-router)# graceful-restart R4(config-router)# exit R4(config)# router bgp 100 R4(config-router)# bgp graceful-restart</pre>
<p>Verification</p>	<p>Run the show command to display the BGP neighbor status.</p>
<p>R2</p>	<pre>R2# show ip ospf Routing Process "ospf 1" with ID 10.0.0.2 Process uptime is 4 minutes Process bound to VRF default Conforms to RFC2328, and RFC1583Compatibility flag is enabled Supports only single TOS(TOS0) routes Supports opaque LSA This router is an ASBR (injecting external routing information) SPF schedule delay 5 secs, Hold time between two SPFs 10 secs LsaGroupPacing: 240 secs Number of incoming current DD exchange neighbors 0/5 Number of outgoing current DD exchange neighbors 0/5 Number of external LSA 4. ```

Common Errors

- GR is not enabled for IGP.
- GR is not enabled for a BGP neighbor device.

5.4.9 Configuring a BGP IPv6 Address Family

Configuration Effect

- Configure BGP IPv6 routes to implement IPv6 network access in different ASs.

Notes

- Generally, BGP uses IPv6 addresses to create neighborships and implement exchange of IPv6 routes.

- In special scenarios (such as the 6PE function, see the MPLS-L3VPN-SCG.doc), BGP supports exchange of IPv6 routes on the neighbors with IPv4 addresses.
- Configurations related to BGP IPv6 services must be configured in the BGP IPv6 address family mode.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring the BGP IPv4 Address Family Mode

- (Optional) Perform this configuration in the BGP configuration mode.

↳ Disabling the IPv4 Address Family Capability for a BGP Neighbor

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

↳ Configuring the BGP IPv6 Address Family Mode

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring the IPv6 Address Family Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.

↳ Configuring IPv6 Route Advertisement in BGP

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).
Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

↘ Configuring the BGP IPv4 Address Family Mode

Command	address-family ipv4 unicast
Parameter	-
Description	
Command Mode	BGP configuration mode
Usage Guide	-

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

Command	no neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command Mode	BGP IPv4 address family mode
Usage Guide	Neighbors with IPv6 addresses are used to exchange IPv6 routes. However, when a neighbor is configured in the BGP mode, BGP automatically activates the IPv4 unicast address family capability for the neighbor. Therefore, you are advised to manually disable the IPv4 unicast address family capability.

↘ Configuring the BGP IPv6 Address Family Mode

Command	address-family ipv6 unicast
Parameter	-
Description	
Command Mode	BGP configuration mode
Usage Guide	-

↘ Configuring the IPv6 Address Family Capability for a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } activate
Parameter	<i>peer-address</i> : Indicates the address of a peer, which is usually an IPv6 address.
Description	<i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters.
Command	BGP IPv6 address family mode

Mode	
Usage Guide	-

↘ **Configuring IPv6 Route Advertisement in BGP**

Command	network <i>network-number</i> [mask <i>mask</i>] [route-map <i>map-tag</i>] [backdoor]
Parameter Description	<i>network-number</i> : Indicates the network number. <i>mask</i> : Indicates the subnet mask. <i>map-tag</i> : Indicates the name of a route map, consisting of no more than 32 characters. backdoor : Indicates that the route is a backdoor route.
Command Mode	BGP IPv6 address family mode
Usage Guide	-

Configuration Example

↘ **Configuring BGP to Implement IPv6 Route Exchange in Different ASs**

Scenario Figure 5-12	<p>The diagram shows two routers, Router A and Router B, connected by a line. Router A is on the left and is associated with AS 65530. Router B is on the right and is associated with AS 65531. Each router is connected to a cloud representing a network.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-12. ● Configure a BGP neighbor, disable the IPv4 address family capability for the neighbor and activate the IPv6 address family capability. ● Configure IPv6 route advertisement in BGP.
A	<pre>A# configure terminal A(config)# int loopback 0 A(config-if-Loopback)# ipv6 address 30::1/128 A(config-if-Loopback)# exit A(config)# router bgp 65530 A(config-router)# neighbor 100::1 remote-as 65531 A(config-router)# address-family ipv4 A(config-router-af)# no neighbor 100::1 activate A(config-router-af)# exit-address-family A(config-router)# address-family ipv6 A(config-router-af)# neighbor 100::1 activate</pre>

	<pre>A(config-router-af)# network 30::1/128</pre>																				
<p>B</p>	<pre>B# configure terminal B(config)# router bgp 65531 B(config-router)# neighbor 100::2 remote-as 65530 B(config-router)# address-family ipv4 B(config-router-af)# no neighbor 100::2 activate B(config-router-af)# exit-address-family B(config-router)# address-family ipv6 B(config-router-af)# neighbor 100::2 activate</pre>																				
<p>Verification</p>	<p>Run the show command to display the BGP neighbor status.</p>

	Total number of prefixes 1
--	----------------------------

Common Errors

- The IPv6 address family capability is not activated for BGP neighbors.
- In non-6PE scenarios, IPv4 addresses are used to establish IPv6 routes for exchange between neighbors.

5.4.10 Configuring Interconnection with Devices Supporting Only 2-Byte AS Numbers

Configuration Effect

- Successfully interconnect devices supporting 4-byte AS numbers with devices supporting only 2-byte AS numbers.

Configuration Steps

↳ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↳ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↳ Configuring the Display Mode of a 4-Byte AS Number

- (Optional) Perform this configuration in the BGP configuration mode. By default, a 4-byte AS number is displayed as decimal digits.

Verification

- Run the **show** command to display the neighbor status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode
Usage Guide	-

↳ Creating a BGP Neighbor

Command	neighbor { <i>peer-address</i> <i>peer-group-name</i> } remote-as <i>as-number</i>
Parameter Description	<i>peer-address</i> : Specifies the address of a peer. This address may be an IPv4 address or an IPv6 address. <i>peer-group-name</i> : Specifies the name of a peer group, consisting of no more than 32 characters. <i>as-number</i> : Indicates the AS number of a BGP peer (group).

Command Mode	BGP configuration mode
Usage Guide	The AS specified for a peer (group) must be the same as the BGP AS number of a BGP speaker at the peer end.

➤ **Configuring the Display Mode of a BGP 4-Byte AS Number**

Command	bgp asnotation dot
Parameter Description	-

Common Errors

N/A

5.4.11 Using Local IPv6 Link Addresses to Establish BGP Neighborships

Configuration Effect

- Use local IPv6 link addresses to establish BGP neighborships.

Notes

- Generally, global IPv4 addresses need to be used for establishing BGP neighborships.
- Local IPv6 link addresses can be used for establishing only single-hop BGP neighborships.
- When local IPv6 link addresses are used for establishing neighborships, using local IPv6 link addresses as information sources must be specified on the peer end.
- When local IPv6 link addresses are used for establishing neighborships, local IPv6 link addresses must be configured on both ends.

Configuration Steps

↘ Enabling BGP

- (Mandatory) Perform this configuration in the global configuration mode.

↘ Creating a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Specifying the Message Source for a BGP Neighbor

- Perform this configuration in the BGP configuration mode. If local IPv6 link addresses are configured for a neighbor, this configuration is mandatory; otherwise, this configuration is optional.

↘ Configuring the BGP IPv4 Address Family Mode

- (Optional) Perform this configuration in the BGP configuration mode.

↘ Disabling the IPv4 Address Family Capability for a BGP Neighbor

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring the BGP IPv6 Address Family Mode

- (Mandatory) Perform this configuration in the BGP configuration mode.

↘ Configuring the IPv6 Address Family Capability for a BGP Neighbor

- (Mandatory) Perform this configuration in the BGP IPv6 configuration mode.

↘ Configuring IPv6 Route Advertisement in BGP

- (Optional) Perform this configuration in the BGP IPv6 configuration mode.

Verification

- Run the **show** command to display the neighbor status.
- Run the **show** command to display the routing status.

Related Commands

↳ Enabling BGP

Command	router bgp <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates an AS number, ranging from 1 to 4,294,967,295, which is 1 to 65535.65535 in the dot mode.
Command Mode	Global configuration mode

Configuration Example

Using a Local IPv6 Link Address for Configuring a BGP Neighborhood to Implement IPv6 Route Exchange in Different ASs

<p>Scenario</p> <p>Figure 5-14</p>	 <p>The diagram illustrates two routers, Router A and Router B, connected by a line representing a network link. Router A is on the left and is associated with AS 65530. Router B is on the right and is associated with AS 65531. Each router is depicted with a cloud-like shape behind it, representing its respective autonomous system.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable BGP on all devices and set the AS numbers as shown in Figure 5-14. ● Configure a BGP neighbor, specify the update-source, disable the IPv4 address family capability for the neighbor and activate the IPv6 address family capability. ● Configure IPv6 route advertisement in BGP.
<p>A</p>	<pre>A# configure terminal A(config)# int loopback 0 A(config-if-Loopback)# ipv6 address 30::1/128 A(config-if-Loopback)# exit A(config)# int GigabitEthernet 0/1 A(config-if-Loopback)# ipv6 address fe80:100::2/64 A(config-if-Loopback)# exit A(config)# router bgp 65530</pre>

	<pre>A(config-router)# neighbor fe80:100::1 remote-as 65531 A(config-router)# neighbor fe80:100::1 update-source GigabitEthernet 0/1 A(config-router)# address-family ipv4 A(config-router-af)# no neighbor fe80:100::1 activate A(config-router-af)# exit-address-family A(config-router)# address-family ipv6 A(config-router-af)# neighbor fe80:100::1 activate A(config-router-af)# network 30::1/128</pre>																				
B	<pre>B# configure terminal A(config)# int GigabitEthernet 0/1 A(config-if-Loopback)# ipv6 address fe80:100::1/64 A(config-if-Loopback)# exit B(config)# router bgp 65531 B(config-router)# neighbor fe80:100::2 remote-as 65530 A(config-router)# neighbor fe80:100::2 update-source GigabitEthernet 0/1 B(config-router)# address-family ipv4 B(config-router-af)# no neighbor fe80:100::2 activate B(config-router-af)# exit-address-family B(config-router)# address-family ipv6 B(config-router-af)# neighbor fe80:100::2 activate</pre>

Network	Next Hop	Metric	LocPrf	Weight Path							
*> 30::1/128	FE80:100::2	0		0 65530 i							

Common Errors

- When a neighborhood is configured, a local IPv6 link address is used to specify the neighborhood; however, no update source is specified as the interface for this local IPv6 link address during local configuration.
- Only one end uses a local IPv6 link address for establishing a neighborhood.

5.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears BGP IPv4 unicast routes.	clear ip bgp [vrf vrf-name] { * as-number peer-address } [soft] [in out] clear bgp ipv4 unicast [vrf vrf-name] { * as-number peer-address } [soft] [in out]
Clears BGP IPv6 unicast routes.	clear bgp ipv6 unicast [vrf vrf-name] { * as-number peer-address } [soft] [in out]

Displaying

Description	Command
Displays BGP IPv4 unicast routes.	show ip bgp show bgp ipv4 unicast
Displays BGP IPv6 unicast routes.	show bgp ipv6 unicast

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables all BGP debugging.	debug ip bgp all
Debugs BGP route flapping.	debug ip bgp dampening
Debugs BGP event processing.	debug ip bgp event
Debugs BGP route filtering.	debug ip bgp filter
Debugs BGP status machine.	debug ip bgp fsm
Debugs BGP neighbor keepalive.	debug ip bgp keepalives
Debugs BGP MPLS processing.	debug ip bgp mpls
Debugs BGP core route processing.	debug ip bgp nsm
Debugs BGP UPDATE packets.	debug ip bgp update

6 Configuring PBR

6.1 Overview

Policy-based routing (PBR) is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured and cannot automatically update with network changes. In addition, PBR is effective only for packets sent from local interfaces and devices. As compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on source and destination addresses, packet length and input interface.

6.2 Applications

Application	Description
Selecting an ISP by Using PBR	Specify preferential output interfaces for packets from different subnets.
Implementing Traffic Classification by Using PBR	Specify QoS values for packets from different subnets.

6.2.1 Selecting an ISP by Using PBR

An existing user network often uses resources of multiple internet server providers (ISPs). PBR needs to be used since different bandwidths may be requested from different ISPs or the network resources for key users need to be protected. By controlling forwarding of certain data packets, you can make full use ISP resources as well as meet the requirements of flexible and diversified applications.

Scenario

Figure 6-1

A LAN has two output interfaces for connecting the Internet. PBR is configured on the layer-3 device DEV1 to enable the two output interfaces to implement load sharing and mutual backup.

The specific requirements are as follows:

- Data streams from subnet 1 are sent from GE 0/1.
- Data streams from subnet 2 are sent from GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Deployment

- Configure two different ACLs on the layer-3 device DEV1:
ACL1: source addresses belong to subnet 1.
ACL2: source addresses belong to subnet 2.
- Configure two policies in the route map on the layer-3 device DEV1:
Policy 1: sets the next hops for packets matching ACL1 to GE0/1 and GE0/2 (Based on the configuration sequence, GE0/1 takes effect first and GE0/2 works in the backup mode).
Policy 2: sets the next hops for packets matching ACL2 to GE0/2 and GE0/1 (Based on the configuration sequence, GE0/2 takes effect first and GE0/1 works in the backup mode).
- Configure PBR on GE0/3 (by using a route map). Then, packets received on this interface are forwarded based on the policies.

6.2.2 Implementing Traffic Classification by Using PBR

Scenario

Networks of medium- and small-sized enterprises have simple structures. Different branch nodes are interconnected to the central nodes through carrier dedicated lines or the Internet VPN mode. Enterprise networks often need to implement

three-in-one integration (of audio, video and data) to maximize the utilization of existing IP networks and save costs. Since all traffic is output from a single output interface, it is necessary to adjust the QoS policies for the output interface, in order to provide preferential communication quality for bandwidth- and delay-sensitive applications.

Figure 6-2

A LAN has an output interface for connecting the Internet. PBR is configured on the layer-3 device DEV1 to change the QoS values for packets from different networks.

The specific requirements are as follows:

- For data streams from subnet 1, representing audio streams, set the DSCP value to 56.
- For data streams from subnet 2, representing video streams, set the DSCP value to 40.
- For data streams from subnet 3, representing data streams, set the DSCP value to 24.

Deployment

- Configure three different ACLs on the layer-3 device DEV1:
 - ACL1: source addresses belong to subnet 1.
 - ACL2: source addresses belong to subnet 2.
 - ACL3: source addresses belong to subnet 3.
- Configure three policies in the route map on the layer-3 device DEV1:
 - Policy 1: sets the DSCP value for packets matching ACL1 to 56.
 - Policy 2: sets the DSCP value for packets matching ACL2 to 40.
 - Policy 3: sets the DSCP value for packets matching ACL3 to 24.
- Configure PBR on GE0/3 (by using a route map). Then, the DSCP values for packets received on this interface are changed based on the policies.

6.3 Features

Feature	Description
Configuring a Policy	Before configuring PBR, configure policies in a route map.
Configuring PBR	Apply a route map including policies to interfaces and devices to implement PBR.

6.3.1 Configuring a Policy

A policy is a "match ..., set..." statement, which indicates that "if certain conditions are matched, perform certain processing actions".

 For detailed introduction to the policies, see the section "Route Map".

Executing Policies

In the global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a policy in a route map.

A route map may contain multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be executed and the route map exits. If no matching condition of any policy is met, no processing action will be performed.

Policies have two working modes:

- permit: When the matching condition of a policy is met, perform the processing action for this policy and exit the route map.
- deny: When the matching condition of a policy is met, do not perform the processing action for this policy and exit the route map.

Matching conditions of policies

The matching conditions of a policy may contain 0, 1 or more matching rules.

- If 0 matching rule is contained, no packet will be matched.
- If one or more match rules are contained, all match rules must be matched at the same time to meet the matching conditions of the policy.

In the route map mode, run the **match** command to configure match rules. One **match** command is mapped to one match rule.

PBR supports the following **match** commands:

Command	Description
---------	-------------

	match ip address	The source IPv4 address (and the destination IPv4 address) is used as the matching condition.  Multiple match ip address commands can be configured in a policy.
IPv6 PBR	match ipv6 address	The source IPv6 address (and the destination IPv6 address) is used as the matching condition.  Only one match ipv6 policy command can be configured in a policy.

-  IPv4 PBR defines the source IP address (and destination IP address) ranges of packets by using the IP standard or extended ACLs. IPv6 PBR defines the source IPv6 address (and destination IPv6 address) ranges of packets by using the IPv6 extended ACLs.
-  On a switch, packet forwarding based on policies of IPv4 PBR interfaces supports expert-level and MAC name ACLs. Packet forwarding based on local policies does not support expert-level and MAC name ACLs.
-  When PBR uses an ACL that is unavailable, the route sub-map will not be matched and the next route sub-map will be matched instead. If no route sub-map is matched, a common route will be selected for forwarding. If only ACLs are configured but no ACE is configured, the PBR forwarding behavior is the same as that in a scenario where an ACL is unavailable.
-  On a non-switch device, packet forwarding based on policies of IPv4 PBR interfaces and local policies do not support expert-level and MAC name ACLs.
-  On a switch, if a route sub-map uses multiple ACLs in PBR, only the first ACL is matched.

Processing action for a policy

The processing action of a policy may contain 0, 1 or more set rules.

- If 0 set rule is contained, no processing action will be performed and the route map will directly exit.
- If one or more set rules are contained, all processing actions will be performed and the route map will exit.

 If set rules have different priorities, the set rule with the highest priority will take effect.

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

PBR supports the following **set** commands:

	Command	Description
IPv4 PBR	set ip tos	Modifies the tos field of an IPv4 packet.  This command cannot work with the set ip dscp command.
	set ip precedence	Modifies the precedence field of an IPv4 packet.  This command cannot work with the set ip dscp command.

	Command	Description
	set ip dscp	<p>Modifies the dscp field of an IPv4 packet.</p> <p> This command cannot work with the set ip tos and set ip precedence commands.</p>
	set ip next-hop	<p>Configures the next hop of IPv4 packet forwarding. The next hop must be directly connected; otherwise, this command is invalid.</p> <p>A packet matching the match rules will be forwarded to the next hop specified by set ip next-hop first, no matter whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR.</p> <p> On a switch, the output interfaces for next hops supported by PBR include the SVI, routing and layer-3 AP interfaces.</p>
	set ip next-hop recursive	<p>Configures the recursive next hop of IPv4 packet forwarding. The next hop can be directly connected or not directly connected. A non-directly-connected next hop will recur to a static or dynamic route in the routing table.</p> <p>This command supports recursion to multiple ECMP next hops of a static or dynamic route. A maximum of 32 next hops are supported. If a recursive route is a static route, only one next hop is supported for the static recursive route.</p> <p>The redundant backup or load balancing mode of multiple recursive next hops is also determined by the ip policy { redundance load-balance } command.</p> <p>A packet matching the match rules will be forwarded to the recursive next hop specified by set ip next-hop recursive first, no matter whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR.</p> <p> Only when a static or dynamic route has an output interface and a next-hop IP address, the policy-based recursive next hop can take effect.</p>
	set ip default next-hop	<p>Configures the default next hop of IPv4 packet forwarding.</p> <p>A packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table.</p>
IPv6 PBR	set ipv6 precedence	<p>Modifies the precedence field of an IPv6 packet.</p> <p> IPv6 PBR does not support set ipv6 tos or set ipv6 dscp.</p>

	Command	Description
	set ipv6 next-hop	Configures the next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the next hop specified by set ipv6 next-hop first, no matter whether the route selected for the IPv6 packet in the routing table is consistent with the next hop specified by PBR. The next hop must be directly connected; otherwise, this command is invalid.
	set ipv6 default next-hop	Configures the default next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table. The next hop must be directly connected; otherwise, this command is invalid.

- i The priority sequence is as follows: **set ip next-hop > set ip next-hop recursive > common route > set ip default next-hop > default route**. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
- i The priority sequence is as follows: **set ipv6 next-hop > common route > set ipv6 default next-hop > default route**. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.
- ✓ For switches, the **set ipv6 default next-hop** command does not take effect for IPv6 addresses whose mask length exceeds 64.

6.3.2 Configuring PBR

PBR

Apply a route map including policies to interfaces or devices to implement PBR.

- Apply a route map to an interface so that packets received by the interface are routed based on the policy. The PBR is often used to control user packets received by a device. This command is effective only for forwarded packets, but not for locally initiated packets.
- Apply a route map to a device so that packets locally initiated are routed based on the policy. The PBR is often used to control protocol packets exchanged between devices (such as ping packets sent locally). This command is effective only for locally initiated packets, but not for forwarded packets.

- i By default, PBR is not unavailable on a device and packets are forwarded based on a routing table.
- ✓ On a switch, the interfaces which support PBR are L3 Ethernet interface, SVI interface and L3 AP interface.

Redundant backup or load balancing

You can set multiple next hops in a policy. Either redundant backup or load balancing can be implemented among multiple next hops. Redundant backup is implemented by default.

i Redundant backup or load balancing is only effective for next hops configured in the **set ip next-hop**, **set ip next-hop recursive**, **set ip default next-hop**, **set ipv6 next-hop** and **set ipv6 default next-hop** commands, and only effective among multiple next hops in the same set rule.

- Redundant backup

Based on the configuration sequence, the first accessible next hop takes effect. When the currently effective next hop (R1) is faulty, the traffic automatically switches to the next accessible next hop (R2). When R1 becomes accessible again, the traffic automatically switches back to R1.

A newly added next hop is arranged at the last of the sequence. Assume that the original sequence of multiple next hops is R1 > R2 > R3. After R1 is deleted and added again, the sequence changes to R2 > R3 > R1.

If no next hop is accessible, packets will be discarded.

- Load balancing

When multiple accessible next hops take effect at the same time, the Weighted Cost Multiple Path (WCMP) and Equal Cost Multiple Path (ECMP) are supported. After an accessible next hop loses effect, traffic will be balanced among the other accessible next hops.

Correlation with BFD

Correlation between PBR and BFD is effective only for next hops configured by the **set ip next-hop** or **set ipv6 next-hop** command.

The **set ip next-hop** and **set ipv6 next-hop** commands carry the **verify-availability** and **bfd [vrf vrf-name] interface-type interface-number gateway** parameters, which can establish correlation between PBR and a BFD session and monitor the accessibility of next hops.

Correlation between PBR and BFD helps enhance the PBR's perception about network environment changes. When BFD detects that the current next hop is not accessible, the BFD will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i For the configuration and related commands for correlation between PBR and BFD, see the "BFD" section.

Correlation with Track

Correlation between PBR and Track is effective only for next hops configured by the **set ip next-hop** command.

The **set ip next-hop** command carries the **verify-availability** and **track track-obj-number** parameters, which can establish correlation between PBR and a Track session and monitor the accessibility of next hops.

Correlation between PBR and Track helps enhance the PBR's perception about network environment changes. When Track detects that the current next hop is not accessible, the Track will immediately notify the PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

i Only IPv4 PBR supports correlation with Track.

i For the configuration and related commands for correlation between PBR and Track, see the "RNS" section.

Source-addressed-based PBR

Run the global configuration commands **ip policy-source in-interface** and **ipv6 policy-source in-interface** to directly generate source-address-based PBR. You do not need to configure a route map.

- If only source IPv4 or Ipv6 addresses need to be matched for packets forwarded by an interface, you can apply the command for source-address-based PBR. The procedure for configuring this command is simpler than that for interface-based PBR.
- If source-address-based PBR is applied to a specified interface, packets received on this interface will be routed based on policies according to the source addresses.
The PBR is often used to control user packets received by a device. This command is effective only for forwarded packets, but not for locally initiated packets.

i Source-address-based PBR has a higher priority than interface-based PBR. If source-address-based PBR and interface-based PBR are applied to the same interface, only interface-based PBR takes effect.

i By default, source-address-based routing is not available on devices and packets are forwarded based on the routing table.

6.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of PBR	 (Mandatory) It is used to apply PBR to forward packets.	
	ip policy route-map	Applies PBR for IPv4 packets received by an interface.
	ipv6 policy route-map	Applies PBR for IPv6 packets received by an interface.
	ip local policy route-map	Applies PBR for IPv4 packets locally initiated.
	ipv6 local policy route-map	Applies PBR for IPv6 packets locally initiated.
Setting Redundant Backup or Load Balancing	 (Optional) It is used to set whether PBR implements redundant backup or load balancing among multiple next hops.	
	ip policy { redundancy load-balance }	Sets whether IPv4 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
	ipv6 policy { redundancy load-balance }	Sets whether IPv6 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
Configuring	 (Optional) It is used to apply source-address-based PBR to forward packets.	

Configuration	Description and Command	
Source-Address-Based PBR	ip policy-source in-interface	Applies source-address-based PBR for IPv4 packets received by an interface.
	ipv6 policy-source in-interface	Applies source-address-based PBR for IPv6 packets received by an interface.

6.4.1 Configuring Basic Functions of PBR

Configuration Effect

Perform personalized routing management for user data streams by preparing flexible policies.

Perform personalized management for protocol interaction and network topologies by preparing flexible policies.

Notes

- A route map must be used when PBR is configured; therefore, you must configure a route map on a device.
- If an ACL is used when the route map is configured, you must configure the ACL on the device.

Configuration Steps

▾ Applying PBR for IPv4 packets received by an interface

- To perform personalized routing management for IPv4 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.
- Run the **ip policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv4 packets received on this interface.

Command	ip policy route-map <i>route-map-name</i>
Parameter	<i>route-map-name</i> : Indicates the name of a route map.
Description	
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one ip policy route-map command can be configured for an interface. If multiple ip policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect.

▾ Applying PBR for IPv6 packets received by an interface

- To perform personalized routing management for IPv6 user data streams passing a device, you should perform this configuration.
- Perform this configuration on the input interface for user data streams.

- Run the **ipv6 policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv6 packets received on this interface.

Command	ipv6 policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one ipv6 policy route-map command can be configured for an interface. If multiple ipv6 policy route-map commands are configured for an interface, only the last configuration takes effect. If the route map used in PBR is unavailable, the PBR does not take effect.

↘ Applying PBR for IPv4 packets locally initiated

- To perform personalized management for IPv4 protocol interaction and IPv4 network topologies, you should perform this configuration.
- Run the **ip local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv4 packets locally initiated.

Command	ip local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ip local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

↘ Applying PBR for IPv6 packets locally initiated

- To perform personalized management for IPv6 protocol interaction and IPv6 network topologies, you should perform this configuration.
- Run the **ipv6 local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv6 packets locally initiated.

Command	ipv6 local policy route-map <i>route-map-name</i>
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Defaults	By default, PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one ipv6 local policy route-map command can be configured for a device. If the route map used in PBR is unavailable, the PBR does not take effect.

Verification

- Check the configurations of PBR.
- Check the configurations of the route map used by PBR.
- If an ACL is used when the route map is configured, you should check the configurations of the ACL.

▾ Checking the configurations of IPv4 PBR

Command	show ip policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Check the interfaces configured with IPv4 PBR according to the output information and the name of the used route map.</p> <pre>Nodexon# show ip policy Banlance mode: redundance Interface Route map local RM_for_PBR_1 GigabitEthernet 0/1 RM_for_PBR_2</pre> <p>Local indicates applying policy-based routing for IPv4 packets locally initiated.</p>

▾ Checking the configurations of IPv6 PBR

Command	show ipv6 policy [<i>route-map-name</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Check the interfaces configured with IPv6 PBR according to the output information and the name of the used route map.</p> <pre>Nodexon#show ipv6 policy Banlance mode: redundance Interface Route map local RM_for_PBR_1 VLAN 1 RM_for_PBR_2</pre> <p>Local indicates applying policy-based routing for IPv6 packets locally initiated.</p>

▾ Checking the configurations of a route map

Command	show route-map [<i>route-map-name</i>]
Parameter	<i>route-map-name</i> : Indicates the name of a route map.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Multiple route maps may be available on a device. Focus on the route map used in PBR and check its policy settings.</p> <pre>Nodexon# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address acl1 Set clauses: ip next-hop 200.24.18.1 route-map RM_FOR_PBR, permit, sequence 20 Match clauses: ip address acl2 Set clauses: ip next-hop 200.24.19.1</pre>

↘ Checking the configurations of an ACL

Command	show access-lists [<i>acl-id</i> <i>acl-name</i>]
Parameter	<i>acl-id</i> : Indicates the ACL ID.
Description	<i>acl-name</i> : Indicates the ACL name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Multiple ACLs may be available on a device. Focus on the ACL used by a route map and check its configurations.</p> <pre>Nodexon# show access-lists 1 ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255</pre>

↘ Checking the routing information of IPv4 PBR

Command	show ip pbr route [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.

Description	local: Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify a local interface or device and check the routing information of IPv4 PBR.</p> <pre>Nodexon# show ip pbr route PBR IPv4 Route Summay : 1 Interface : GigabitEthernet 0/1 Sequence : 10 Min Length : None Max Length : None VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Tos_Dscp : None Precedence : None Tos_Dscp : 0 Precedence : 0 Mode : redundance Nexthop Count : 1 Nexthop[0] : 192.168.8.100 Weight[0] : 1 Ifindex[0] : 2</pre>

📌 **Checking the routing information of IPv6 PBR**

Command	show ipv6 pbr route [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local: Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify a local interface or device and check the routing information of IPv6 PBR.</p> <pre>Nodexon# show ipv6 pbr route PBR IPv6 Route Summary : 1</pre>

Interface	: GigabitEthernet 0/1
Sequence	: 10
ACL[0]	: 2900
ACL_CLS[0]	: 5
Min Length	: None
Max Length	: None
VRF ID	: 0
Route Flags	:
Route Type	: PBR
Direct	: Permit
Priority	: High
Tos_Dscp	: None
Precedence	: None
Tos_Dscp	: 0
Precedence	: 0
Mode	: redundancy
NextHop Count	: 1
NextHop[0]	: 10::2
Weight[0]	: 1
Ifindex[0]	: 2

📌 **Checking a route map used by IPv4 PBR**

Command	show ip pbr route-map <i>rmap-name</i>
Parameter Description	<i>rmap-name</i> : Indicates the route map name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a route map and check the route map used by IPv4 PBR. <pre>Nodexon# show ip pbr route-map rm PBR VRF: GLOBAL, ID: 0 Forward Mode: redundancy Forwarding: On</pre>

```
Route-map rm

Route-map index: Sequence 10, permit

Match rule:

  ACL ID :   2900, CLS: 1, Name: acl1

Set rule:

  IPv4 nexthop: 192.168.8.100, (VRF name: , ID: 0), Weight: 0

  PBR state info ifx: 2, Connected: True, Track state: Up
```

📌 **Checking a route map used by IPv6 PBR**

Command	show ipv6 pbr route-map <i>rmap-name</i>
Parameter	<i>rmap-name</i> : Indicates the route map name.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Specify a route map and check the route map used by IPv6 PBR. <pre>Nodexon# show ipv6 pbr route-map rm6 PBR VRF: GLOBAL, ID: 0 Forward Mode: redundance Forwarding: On Route-map rm6 Route-map index: Sequence 10, permit Match rule: ACL ID : 2901, CLS: 5, Name: acl6 Set rule: IPv6 nexthop: 10::2, (VRF name: , ID: 0), Weight: 0 PBR state info ifx: 2, Connected: True, Track state: Up</pre>

📌 **Checking the statistics about packets forwarded by IPv4 PBR**

Command	show ip pbr statistics [interface <i>if-name</i> local]
Parameter	<i>if-name</i> : Indicates an interface name.
Description	local : Indicates local.
Command Mode	Privilege, global and interface configuration modes

Usage Guide	<pre>Nodexon# show ip pbr statistics IPv4 Policy-based route statistic gigabitEthernet 0/1 statistics : 10</pre>
--------------------	---

↘ **Checking the statistics about packets forwarded by IPv6 PBR**

Command	show ipv6 pbr statistics [interface <i>if-name</i> local]
Parameter Description	<i>if-name</i> : Indicates an interface name. local : Indicates local.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<pre>Nodexon# show ipv6 pbr statistics IPv6 Policy-based route statistic gigabitEthernet 0/1 statistics : 20</pre>

Configuration Example

↘ **Configuring IPv4 PBR and selecting an output link based on source addresses of packets**

<p>Scenario</p> <p>Figure 6-3</p>	<pre> graph TD Internet((Internet)) --- G01[G 0/1] --- DEV1[Layer-3 device DEV1] Internet --- G02[G 0/2] --- DEV1 DEV1 --- G03[G 0/3] --- Subnet1((Subnet 1)) DEV1 --- G03 --- Subnet2((Subnet 2)) style Internet fill:#004a7c,color:#fff style Subnet1 fill:#004a7c,color:#fff style Subnet2 fill:#004a7c,color:#fff </pre>
	<p>The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24.</p> <p>DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.</p>

	<p>This LAN has two output interfaces for connecting the Internet. The requirements are as follows:</p> <ul style="list-style-type: none"> ● Data streams from subnet 1 for accessing the Internet should pass GE 0/1. ● Data streams from subnet 2 for accessing the Internet should pass GE 0/2. ● If the GE 0/1 link is disconnected, the data streams on the GE 0/1 interface are switched to the GE 0/2 interface. Vice versa.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure two ACLs to match packets from subnets 1 and 2 respectively. ● Set a policy to set the next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.) ● Set a policy to set the next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.) ● Apply the policy to GE 0/3. ● Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.) <p> During redundant backup, based on the configuration sequence, the first next hop takes effect first.</p>
	<pre> DEV1(config)# access-list 1 permit 200.24.16.0 0.0.0.255 DEV1(config)# access-list 2 permit 200.24.17.0 0.0.0.255 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 2 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundancy </pre>

➤ Configuring IPv6 PBR and selecting an output link based on source addresses of packets

Scenario
Figure 6-4

DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64 whereas the network segment where subnet 2 resides is 2004::/64. DEV1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 2001::1/64 and 2002::1/64.

This LAN has two output interfaces for connecting the Internet. The requirements are as follows:

- Data streams from subnet 1 for accessing the Internet should pass GE 0/1.
- Data streams from subnet 2 for accessing the Internet should pass GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on the GE 0/1 interface are switched to the GE 0/2 interface. Vice versa.

Configuration Steps

- Configure two ACLs to match packets from subnets 1 and 2 respectively.
- Set a policy to set the next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.)
- Set a policy to set the next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.)
- Apply the policy to GE 0/3.
- Set PBR to implement redundant backup among multiple next hops.

i During redundant backup, based on the configuration sequence, the first next hop takes effect first.

```
DEV1(config)# ipv6 access-list net1
DEV1(config-ipv6-acl)# permit ipv6 2003::/64 any
DEV1(config-ipv6-acl)# exit
DEV1(config)# ipv6 access-list net2
DEV1(config-ipv6-acl)# permit ipv6 2004::/64 any
```

	<pre> DEV1(config-ipv6-acl)# exit DEV1(config)# route-map RM_FOR_PBR 30 DEV1(config-route-map)# match ipv6 address net1 DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 40 DEV1(config-route-map)# match ipv6 address net2 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ipv6 policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ipv6 policy redundance </pre>
Verification	<ul style="list-style-type: none"> ● Check the configurations of IPv6 PBR. ● Check the configurations of the route map. ● Check the configurations of an ACL.
	<pre> DEV1# show ipv6 policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR </pre>
	<pre> DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 11 Match clauses: ipv6 address net1 Set clauses: ipv6 next-hop 2001::1 2002::1 route-map RM_FOR_PBR, permit, sequence 21 Match clauses: ipv6 address net2 Set clauses: </pre>

<pre>ipv6 next-hop 2002::1 2001::1</pre>
<pre>DEV1# show access-lists ipv6 access-list net1 10 permit ipv6 2003::/64 any (0 packets matched) ipv6 access-list net2 10 permit ipv6 2004::/64 any (0 packets matched)</pre>

↘ **Configuring correlation between IPv4 PBR and Track**

<p>Scenario Figure 6-5</p>	<p>The diagram illustrates a network topology. At the top, a cloud labeled 'Internet' is connected to a 'Layer-3 device DEV1' through two interfaces: G0/1 (with IP 200.24.18.1) and G0/2 (with IP 200.24.19.1). Below DEV1, interface G0/3 is connected to two subnets: 'Subnet 1' (200.24.16.0/24) and 'Subnet 2' (200.24.17.0/24).</p>
	<p>The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24.</p> <p>DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.</p>
	<ul style="list-style-type: none"> ● DEV1 can fast detect a faulty output link and switch to a backup link.
<p>Configuration Steps</p>	<p>When configuring IPv4 PBR and selecting an output link based on source addresses of the packets, add or modify the following configurations (red fields):</p> <ul style="list-style-type: none"> ● Set two Track objects and track the accessibility of the next hops of the two output interfaces. ● When configuring a policy, set the correlation between the next hops and the Track objects.
<p>DEV1</p>	<pre>DEV1(config)# ip access-list extended 101 DEV1(config-ip-acl)# permit ip 200.24.16.0 0.0.0.255 any</pre>

```

DEV1(config-ip-acl)# exit
DEV1(config)# ip access-list extended 102
DEV1(config-ip-acl)# permit ip 200.24.17.0 0.0.0.255 any
DEV1(config-ip-acl)# exit
DEV1(config)#ip rns 1
DEV1(config-ip-rns)#icmp-echo 200.24.18.1
DEV1(config)#ip rns schedule 1 start-time now life forever

1 change, current state last: 130 secs
Delay up 30 secs, down 50 secs
    
```

➤ **Configuring IPv4 recursive PBR, selecting an output link based on source addresses of the packets, and recurring to the output link of a dynamic route**

<p>Scenario Figure 6-6</p>	
	<p>The layer-3 device DEV 1 is connected to subnet 1 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24.</p> <p>DEV 1 is connected to subnet 2 through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.</p>
	<p>Subnet 1 is connected to subnet 2 through two output interfaces of DEV1. The requirements are as follows:</p> <ul style="list-style-type: none"> ● Configure static or dynamic routes in advance to ensure that static or dynamic routes in the network segment 200.24.20.0 are available in the routing table of DEV1. ● Data streams from subnet 1 for accessing the Internet can recur to a dynamic route whose IP address is 200.24.20.1. ● If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an ACL to match packets from subnet 1. ● Set a policy to set the recursive next hop for packets from subnet 1 to 200.24.20.1. ● Apply the policy to GE 0/3. ● Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.) <p>i During redundant backup, the sequence for the next hops to take effect is related to the sequence for the static or dynamic routes to take effect.</p>
	<pre>DEV1(config)# access-list 1 permit 200.24.16.0 0.0.0.255</pre>

	<pre> DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 1 DEV1(config-route-map)# set ip next-hop recursive 200.24.20.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundance </pre>				
Verification	<ul style="list-style-type: none"> ● Check the configurations of IPv4 PBR. ● Check the configurations of the route map. ● Check the configurations of the ACLs. 				
	<pre> DEV1# show ip policy </pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Route map</th> </tr> </thead> <tbody> <tr> <td>GigabitEthernet 0/3</td> <td>RM_FOR_PBR</td> </tr> </tbody> </table>	Interface	Route map	GigabitEthernet 0/3	RM_FOR_PBR
Interface	Route map				
GigabitEthernet 0/3	RM_FOR_PBR				
	<pre> DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop recursive 200.24.20.1 </pre>				
	<pre> DEV1# show access-lists ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255 </pre>				

Common Errors

- A route map is used when PBR is configured but the route map does not exist.
- An ACL is used when a route map is configured but the ACL does not exist.

6.4.2 Setting Redundant Backup or Load Balancing

Configuration Effect

- Using multiple next hops in the mutual backup mode can enhance the network reliability.

- Implementing load balancing among multiple next hops can expand the network bandwidth.

Notes

- The basic functions of PBR must be configured.
- Redundant backup and load balancing are effective only for the next hops set by the following **set** commands.

Command	Description
set ip next-hop	Configures the next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ip default next-hop	Configures the default next hop of IPv4 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 next-hop	Configures the next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ipv6 default next-hop	Configures the default next hop of IPv6 packets. This command carries the <i>weight</i> parameter, which is used to set the weight of the WCMP. The default value is 1.
set ip next-hop recursive	Configures the recursive next hop of IPv4 packets. Only one command can be configured for a route map and packets can recur to multiple next hops (up to 32 next hops) of a static or dynamic ECMP route. The redundant backup or load balancing mode for recurring to multiple next hops is also determined by the ip policy { redundancy load-balance } command.

i Up to eight next hops can be set for WCMP whereas up to 32 next hops can be set for ECMP.

Configuration Steps

⤵ Setting whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ip policy { redundancy load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

⤵ Setting whether Ipv6 PBR implements redundant backup or load balancing among multiple next hops

- If load balancing needs to be implemented among multiple next hops, this configuration needs to be performed.
- If load balancing is configured at present, you also need to perform this configuration to reset redundant backup.
- This configuration is effective for all PBRs configured on a device.

Command	ipv6 policy { redundance load-balance }
Parameter	redundance: Indicates redundant backup.
Description	load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect at the same time and share traffic by weight.

Verification

- Check whether redundant backup or load balancing is implemented among multiple next hops.

▾ Checking whether IPv4 PBR implements redundant backup or load balancing among multiple next hops

Command	show ip policy [route-map-name]
Parameter Description	route-map-name: Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre>Nodexon# show ip policy Banlance mode: redundance Interface Route map local test GigabitEthernet 0/3 test</pre>

▾ Checking whether IPv6 PBR implements redundant backup or load balancing among multiple next hops

Command	show ipv6 policy [route-map-name]
Parameter Description	route-map-name: Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	See the following example and focus on the red field. <pre>Nodexon#show ipv6 policy Banlance mode: redundance Interface Route map VLAN 1 RM_for_Vlan_1 VLAN 2 RM_for_Vlan_2</pre>

6.4.3 Configuring Source-Address-Based PBR

Configuration Effect

Perform personalized routing management for IPv4 or IPv6 addresses of user data streams by preparing flexible policies.

Notes

- Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.

Configuration Steps

▾ Applying source-address-based PBR for IPv4 packets received by an interface

- To perform personalized routing management based on source IPv4 addresses for IPv4 user data streams passing a device, you should perform this configuration.
- The global configuration takes effect on the input interface of specified user data streams.
- Run the **ip policy-source in-interface** command to perform source-address-based PBR for IPv4 packets received by a specified interface.

Command	ip policy-source in-interface <i>interface-type</i> <i>sequence</i> { <i>source-address mask</i> <i>source-address/mask</i> } [[default] next-hop <i>ip-address</i> [<i>weight</i>]
Parameter Description	<i>interface-type</i> : Specifies the type of an interface to which source-address PBR is applied. <i>sequence</i> : Indicates the sequence number of a policy. A smaller sequence number means a higher priority. <i>source-address</i> : Indicates the source IPv4 address. <i>mask</i> : Indicates the mask of the source IPv4 address. <i>ip-address</i> : Indicates the next-hop IPv4 address. <i>weight</i> : Indicates the weight of a next hop.
Defaults	By default, source-address-based PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Configure multiple ip policy-source in-interface commands for the same interface. The sequence numbers of different source addresses are different. A smaller sequence number means a higher priority of the source-address-based PBR. When the sequence number is the same, the priorities of next hops are as follows: next-hop ip-address > default next-hop ip-address ; Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.

▾ Applying source-address-based PBR for IPv6 packets received by an interface

- To perform personalized routing management based on source IPv6 addresses for IPv6 user data streams passing a device, you should perform this configuration.
- The global configuration takes effect on the input interface of specified user data streams.
- Run the **ipv6 policy-source in-interface** command to perform source-address-based PBR for IPv6 packets received by a specified interface.

Command	ipv6 policy-source in-interface <i>interface-type</i> <i>sequence</i> { <i>source-address/prefix-length</i> } [[default] next-hop <i>ipv6-address</i> [<i>weight</i>]
Parameter Description	<i>interface-type</i> : Specifies the type of an interface to which source-address PBR is applied. <i>sequence</i> : Indicates the sequence number of a policy. A smaller sequence number means a higher priority.

	<p><i>source-address</i>: Indicates the source IPv6 address.</p> <p><i>prefix-length</i>: Indicates the prefix length of a source IPv6 address.</p> <p><i>ipv6-address</i>: Indicates the next-hop IPv6 address.</p> <p><i>weight</i>: Indicates the weight of a next hop.</p>
Defaults	By default, source-address-based PBR is unavailable on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	<p>Configure multiple ipv6 policy-source in-interface commands for the same interface. The sequence numbers of different source addresses are different. A smaller sequence number means a higher priority of the source-address-based PBR.</p> <p>When the sequence number is the same, the priorities of next hops are as follows: next-hop ipv6-address > default next-hop ipv6-address e.</p> <p>Source-address-based PBR has a higher priority than interface-based PBR. When they are applied to an interface at the same time, interface-based PBR takes effect whereas source-address-based PBR does not take effect.</p>

Verification

📄 Checking the routing information of source-address-based IPv4 PBR

Command	show ip pbr source-route [interface <i>if-name</i>]
Parameter Description	<i>if-name</i> : Indicates an interface name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify an interface and check the routing information of IPv4 source-address-based PBR.</p> <pre>Nodexon# show ip pbr source-route PBR IPv4 Source Route Interface : GigabitEthernet 0/1 Sequence : 10 Source address : 10.1.1.1/24 VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Match_ipaddr : Exist Mode : redundance</pre>

	<pre> Nexthop Count : 1 Nexthop[0] : 192.168.8.100 Weight[0] : 1 Ifindex[0] : 2 </pre>
--	--

↘ **Checking the routing information of IPv6 PBR**

Command	show ipv6 pbr source-route [interface <i>if-name</i>]
Parameter Description	<i>if-name</i> : Indicates an interface name.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>Specify an interface and check the routing information of IPv6 PBR.</p> <pre> Nodexon# show ipv6 pbr source-route PBR IPv6 Source Route Interface : GigabitEthernet 0/1 Sequence : 10 Source address : 1000::1/64 VRF ID : 0 Route Flags : Route Type : PBR Direct : Permit Priority : High Match_ipaddr : Exist Mode : redundance Nexthop Count : 1 Nexthop[0] : 1001::2 Weight[0] : 1 Ifindex[0] : 3 </pre>

Configuration Example

↘ **Configuring IPv4 source-address-based PBR and selecting an output link based on source addresses of packets**

Scenario
Figure 6-9

The layer-3 device DEV 1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24 whereas the network segment where subnet 2 resides is 200.24.17.0/24. DEV 1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.

This LAN has two output interfaces for connecting the Internet. The requirements are as follows:

- Data streams from subnet 1 for accessing the Internet should pass GE 0/1.
- Data streams from subnet 2 for accessing the Internet should pass GE 0/2.
- If the GE 0/1 link is disconnected, the data streams on GE 0/1 are switched to GE 0/2. Vice versa.

Configuration Steps

- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.)
- Set source-address-based PBR and set the next hops for packets from the GE0/3 subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.)
- Set PBR to implement redundant backup among multiple next hops. (The default setting is redundant backup.)

i During redundant backup, based on the configuration sequence, the first next hop takes effect first.

```
DEV1(config)# ip policy-source in-interface gigabitEthernet 0/3 1 200.24.16.0/24 next-hop
200.24.18.1 200.24.19.1

DEV1(config)# ip policy-source in-interface gigabitEthernet 0/3 2 200.24.17.0/24 next-hop
200.24.19.1 200.24.18.1

DEV1(config)# ip policy redundancy
```

Verification

- Check the routing information of source-address-based IPv4 PBR.

```
DEV1# show ip pbr source-route
PBR IPv4 Source Route

```

6.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics about packets forwarded by IPv4 PBR.	clear ip pbr statistics [interface <i>if-name</i> local]
Clears the statistics about packets forwarded by IPv6 PBR.	clear ipv6 pbr statistics [interface <i>if-name</i> local]

Displaying

Description	Command
Displays the configurations of IPv4 PBR.	show ip policy
Displays the configurations of IPv6 PBR.	show ipv6 policy
Displays the configurations of a route map.	show route-map [name]
Displays the configurations of an ACL.	show access-list
Displays the correlation between IPv4 PBR and BFD.	show ip pbr bfd
Displays the correlation between IPv6 PBR and BFD.	show ipv6 pbr bfd
Displays the routing information of IPv4 PBR.	show ip pbr route [interface <i>if-name</i> local]

Description	Command
Displays the routing information of IPv6 PBR.	show ipv6 pbr route [interface <i>if-name</i> local]
Displays a route map used by IPv4 PBR.	show ip pbr route-map <i>rmap-name</i>
Displays a route map used by IPv6 PBR.	show ipv6 pbr route-map <i>rmap-name</i>
Displays the routing information of IPv4 source-address-based PBR.	show ip pbr source-route [interface <i>if-name</i>]
Displays the routing information of IPv6 source-address-based PBR.	show ipv6 pbr source-route [interface <i>if-name</i>]
Displays the statistics about IPv4 PBR.	show ip pbr statistics [interface <i>if-name</i> local]
Displays the statistics about IPv6 PBR.	show ipv6 pbr statistics [interface <i>if-name</i> local]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs PBR errors.	debug pbr error
Debugs PBR events.	debug pbr events
Debugs multiple service cards supported by PBR.	debug pbr ms
Debugs PBR message communication.	debug pbr msg
Debugs interaction between PBR and NSM.	debug pbr nsm
Debugs packet forwarding of PBR.	debug pbr packet
Debugs PBR GR.	debug pbr restart

7 Configuring VRF

7.1 Overview

A Virtual Private Network (VPN) Routing and Forwarding (VRF) table is used for the forwarding of VPN packets. Each VPN corresponds to a VRF table.

A device that provides the VPN service has multiple routing tables, including a public network routing table and one or multiple VRF tables. The public-network routing table is used for the forwarding of public network packets, and the VRF tables are used for the forwarding of VPN packets. These routing tables are created to separate routes in the public network from those in VPNs and separate routes in different VPNs.

i A VPN is a private dedicated network built in the public network. "Virtual" means that the VPN is logically exclusive, instead of physically exclusive.

Protocols and Standards

- RFC4364: BGP/MPLS IP Virtual Private Networks (VPNs)

7.2 Applications

Application	Description
Local Inter-VPN Access	Provide the VPN service on a routing device and enable VPNs to access each other.
VRF only on Provider Edges (PEs)	Provide the VPN service in an IP/Multiprotocol Label Switching (MPLS) network and connect one Customer Edge (CE) to one VPN.
VRF on CEs and PEs	Provide the VPN service in an IP/ MPLS network and connect one CE to multiple VPNs.

i CE: An edge device in a customer network

i PE: An edge device in a Service Provider (SP) network

7.2.1 Local Inter-VPN Access

Scenario

Provide the VPN service on a routing device and enable VPNs to access each other.

In Figure 7-1, Sub a runs the Routing Information Protocol (RIP), Sub b runs the Open Shortest Path First (OSPF) protocol, and Servers is a network segment directly connected to C. Provide the VPN service on C to Sub a, Sub b, and Servers, and enable Sub a and Sub b to access Servers.

Figure 7-1

Related Configuration

- On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP.
- On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF.
- On C, create a VRF table for Servers and bind the interface directly connected to Servers.
- On C, configure the route targets (RTs) of the VRF tables for Suba, Subb, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b.
- Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b, and introduce the direct routes to the VRF table for Servers.

7.2.2 VRF only on PEs

Scenario

An Internet Service Provider (ISP) provides the VPN service in an IP/MPLS backbone network.

In Figure 7-2, VPN1 runs RIP, and VPN2 runs OSPF.

- One CE is connected to one VPN, and all routes on the CE are exclusively used by the connected VPN. Therefore, no VRF table needs to be created to separate the routes.
- On each PE, VRF tables must be created to separate the routes in VPN1, those in VPN2, and those in the public network from each other.

Figure 7-2

Deployment

- On PE1, create a VRF table for VPN1 and bind the interface directly connected to CE1. On PE2, create a VRF table for VPN1 and bind the interface directly connected to CE3.
- On PE1, create a VRF table for VPN2 and bind the interface directly connected to CE2. On PE2, create a VRF table for VPN2 and bind the interface directly connected to CE4.
- On PE1, associate the VRF table for VPN1 with CE1 by using RIP. On PE2, associate the VRF table for VPN1 with CE3 by using RIP.
- On PE1, associate the VRF table for VPN2 with CE2 by using OSPF. On PE2, associate the VRF table for VPN2 with CE4 by using OSPF.
- Create a BGP neighbor (VPNv4 address family) between PE1 and PE2.
- In the VRF instance for VPN1 on PE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on PE2 is similar.
- In the VRF instance for VPN2 on PE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on PE2 is similar.

i For details about the application scenario, see "Configuration Guide > MPLS > L3 VPN".

7.2.3 VRF on CEs and PEs (MCE Application)

Scenario

An ISP provides the VPN service in an IP/MPLS backbone network.

In Figure 7-3, VPN a runs RIP, VPN b runs OSPF, and PE1 and PE2 are connected to BGP/MPLS VPNs.

- One Multi-VPN-Instance CE (MCE) is connected to multiple VPNs. VRF tables must be created to separate the routes in VPN a from those in VPN b.
- On each PE, VRF tables must be created to separate the routes in VPN a, those in VPN b, and those in the public network from each other.

Figure 7-3

Deployment

- On MCE1, create VRF tables for VPN a and VPN b respectively, bind the interfaces directly connected to VPN a and VPN b, and bind the VLAN interface connected to PE1. The configuration on MCE2 is similar.

- On PE1, create VRF tables for VPN a and VPN b respectively, and bind the VLAN interface connected to MCE1. The configuration on PE2 is similar.
- On MCE1, associate the VRF table for VPN a with VPN a by using RIP. The configuration on MCE2 is similar.
- On MCE1, associate the VRF table for VPN b with VPN b by using OSPF. The configuration on MCE2 is similar.
- Create a BGP neighbor (VPNv4 address family) between PE1 and PE2.
- In the VRF instance for VPN a on MCE1, redistribute RIP routes to BGP, and redistribute BGP routes to RIP. The configuration on MCE2 is similar.
- In the VRF instance for VPN b on MCE1, redistribute OSPF routes to BGP, and redistribute BGP routes to OSPF. The configuration on MCE2 is similar.

 For details about the application scenario, see "Configuration Guide > MPLS > L3 VPN".

7.3 Features

Overview

Feature	Description
VPN Instance	A VPN instance is used to provide the VPN service. It is typically represented by a VRF table.
VPN Route	A VPN route is used to forward VPN packets.
VPN Route Attribute	Route distinguisher (RD): Identifies the VPN to which a route belongs. RT: Indicates the route trade-off mode of VRF.

7.3.1 VPN Instance

A VPN instance is used to provide the VPN service. On a device that provides the VPN service, a VPN instance consists of the VRF table, interfaces, routing protocol processes, and configuration that belong to the same VPN. A VPN instance is typically represented by a VRF table.

Working Principle

A PE exchanges routes with a CE by using the related routing protocol in the corresponding VPN instance. A VRF table is bound to a specific interface to generate its interface set. Packets received on these interfaces will be associated with the VRF table and forwarded along corresponding routes.

Related Configuration

 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. Single-protocol VRF tables only support IPv4, whereas multiprotocol VRF tables support IPv4 and IPv6.

[Configuring a Single-Protocol VRF Table](#)

By default, a device has no VRF table.

Run the **ip vrf** command to create a single-protocol VRF table.

Run the **ip vrf forwarding** command to bind an interface.

Currently, single-protocol VRF tables only support IPv4.

📌 **Configuring a Multiprotocol VRF Table**

By default, a device has no VRF table.

Run the **vrf definition** command to create a multiprotocol VRF table.

Run the **address-family ipv4** command to enable the IPv4 address family.

Run the **address-family ipv6** command to enable the IPv6 address family.

Run the **vrf forwarding** command to bind an interface.

Multiprotocol VRF tables support IPv4 and IPv6.

7.3.2 VPN Route

A VPN route is only used to forward VPN packets. It comes from:

- Direct route and host route on the bound interface
- Direct route and host route on the configured import interface (not bound)
- Static and dynamic routes (RIP, RIPng, OSPFv2, ISIS, and BGP) in the configured VPN instance

i For details about the static routes in a VPN instance, see "Configuration Guide > IP Route".

i For details about RIP in a VPN instance, see "Configuration Guide > IP Route > RIP".

i For details about RIPng in a VPN instance, see "Configuration Guide > IP Route > RIPng".

i For details about OSPFv2 in a VPN instance, see "Configuration Guide > IP Route > OSPFv2".

i For details about OSPFv3 in a VPN instance, see "Configuration Guide > IP Route > OSPFv3".

i For details about ISIS in a VPN instance, see "Configuration Guide > IP Route > ISIS".

i For details about BGP in a VPN instance, see "Configuration Guide > IP Route > BGP".

7.3.3 VPN Route Attribute

The BGP extended attributes include two attributes specific to VPN routes: RD and RT.

Working Principle

📌 **RD**

Two routes with the same address but different RDs in two VRF tables can be advertised separately between PEs, because the routes are sent together with their RDs through multiprotocol BGP (MP-BGP).

📌 **RT**

RT in essence indicates each VRF table's route trade-off and preferences. It is mainly used to control the advertising and installation policies for VPN routes. RT is divided into the import attribute and export attribute. The import attribute indicates

the route of interest, and the export attribute indicates the advertised route. A PE advertises a route to other PEs based on the RT export rule in the corresponding VRF table. The peer PE checks all received routes against the RT import rule in each VRF table. If a route matches an RT export rule (the export rule contains the import rule), it will be added to the corresponding VRF table.

Related Configuration

RD

By default, no RD is configured in VRF mode.

Run the **rd** command to configure an RD.

RT

By default, no RT is configured in VRF mode or address family mode.

Run the **route-target { import | export | both }** command to configure an RT.

7.4 Configuration

Configuration	Description and Command	
Configuring a Single-Protocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table; otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 network. IPv6 is not supported.	
	ip vrf <i>vrf-name</i>	Creates a VRF table.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.
	ip vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
ip vrf receive <i>vrf_name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.	
Configuring a Multiprotocol VRF Table	 Single-protocol VRF tables and multiprotocol VRF tables cannot be created at the same time. If IPv6 is supported, configure a multiprotocol VRF table. otherwise, you can configure a single-protocol VRF table or a multiprotocol VRF table. This configuration item creates a VRF table in an IPv4 or IPv6 network.	
	vrf definition <i>vrf-name</i>	Creates a VRF table.
	description <i>string</i>	Configures a VRF descriptor.
	rd <i>rd_value</i>	Configures an RD.
	route-target { import export both } <i>rt_value</i>	Configures an RT.

Configuration	Description and Command	
	address-family ipv4	Enables the IPv4 address family.
	address-family ipv6	Enables the IPv6 address family.
	vrf forwarding <i>vrf-name</i>	Binds an interface and adds the direct route and host route on the interface to a VRF table.
	vrf receive <i>vrf-name</i>	Adds the direct route and host route on an interface to a VRF table without binding the interface.

7.4.1 Configuring a Single-Protocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP/MPLS backbone network.
- Only IPv4 is supported.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.
- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

↘ Creating a VRF Table

- Mandatory.
- Create a VRF table for each VPN.

↘ Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.
- Run the **rd** command in single-protocol VRF mode.

↘ Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in single-protocol VRF mode.

↘ Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).
- If you bind an interface to the corresponding single-protocol VRF table and enable IPv6 on the interface, the device cannot forward the IPv6 packets received on the interface.

↘ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If policy-based routing (PBR) is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether VRF tables are created correctly on the router.

Related Commands

↘ Creating a VRF Table

Command	ip vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

↘ Configuring an RD

Command	rd <i>rd_value</i>
----------------	---------------------------

Parameter Description	<p><i>rd_value</i> has the following three different parameter forms:</p> <p>(1) <i>rd_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public autonomous system (AS). nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rd_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rd_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode
Usage Guide	<p>You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD.</p> <p>A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.</p>

📌 Configuring an RT

Command	route-target { import export both } <i>rt_value</i>
Parameter Description	<p><i>rt_value</i> has the following three different parameter forms:</p> <p>(1) <i>rt_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rt_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rt_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>
Command Mode	VRF configuration mode
Usage Guide	A VRF table can be configured with multiple import and export RT attributes.

📌 Binding an Interface

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	<p>By default, an interface does not belong to any VRF table.</p> <p>After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table.</p> <p>You must bind an interface to the corresponding single-protocol VRF table before you configure the IPv4 address of the interface. If you bind the interface after its IPv4 address is configured, the IPv4 address will be invalid (the IPv6 address of the interface is retained).</p>

Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	ip vrf receive <i>vrf-name</i>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Interface configuration mode
Usage Guide	This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the ip vrf forwarding command, the ip vrf receive command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table. The ip vrf forwarding and ip vrf receive commands are mutually exclusive on the same interface.

Displaying the VRF Information on a Device

Command	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Parameter	brief : Displays brief information.
Description	detail : Displays detailed information. interfaces : Displays the interface binding information. <i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.

Displaying the Routes in a VRF Table

Command	show ip route vrf <i>vrf-name</i>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

Local Inter-VPN Access

Scenario Figure 7-4	<p>The diagram illustrates a network topology for local inter-VPN access. It features three VPNs: 'Sub a' (top left), 'Sub b' (bottom left), and 'Servers' (right). Each VPN is represented by a cloud icon. A central router, labeled 'C', is connected to both 'Sub a' and 'Sub b'. Router 'C' is also connected to the 'Servers' cloud. The routers are labeled 'A', 'B', and 'C' respectively.</p>
	Sub a, Sub b, and Servers are three VPNs that have separate address spaces.

	Sub a runs RIP, Sub b runs OSPF, and Servers is a network segment directly connected to C.																								
Configuration Requirements	Routes in Sub a are separated from those in Sub b, but both Sub a and Sub b can access Servers.																								
Configuration Steps	<ul style="list-style-type: none"> On C, create a VRF table for Sub a, bind the interface directly connected to A, and associate the VRF table with A by using RIP. On C, create a VRF table for Sub b, bind the interface directly connected to B, and associate the VRF table with B by using OSPF. On C, create a VRF table for Servers and bind the interface directly connected to Servers. On C, configure the RTs of the VRF tables for Sub a, Sub b, and Servers. Import the routes in the VRF tables for Sub a and Sub b to the VRF table for Servers, and import the routes in the VRF table for Servers to the VRF tables for Sub a and Sub b. Configure the Border Gateway Protocol (BGP) on C. Introduce the RIP routes to the VRF table for Sub a, introduce the OSPF routes to the VRF table for Sub b (enabled with an address family), and introduce the direct routes to the VRF table for Servers (enabled with an address family). <p> Planning of interfaces and addresses:</p> <table border="1"> <thead> <tr> <th>Interface Description</th> <th>Interface Name</th> <th>IP Address/Mask</th> <th>VRF Table</th> </tr> </thead> <tbody> <tr> <td>Interface on C connected to A</td> <td>GE0/1</td> <td>10.10.1.1/24</td> <td>VRF table for Sub a</td> </tr> <tr> <td>Interface on C connected to B</td> <td>GE0/2</td> <td>10.10.2.1/24</td> <td>VRF table for Sub b</td> </tr> <tr> <td>Interface on C connected to Servers</td> <td>GE0/3</td> <td>10.10.3.1/24</td> <td>VRF table for Servers</td> </tr> <tr> <td>Interface on A connected to C</td> <td>GE0/1</td> <td>10.10.1.2/24</td> <td>-</td> </tr> <tr> <td>Interface on B connected to C</td> <td>GE0/2</td> <td>10.10.2.2/24</td> <td>-</td> </tr> </tbody> </table>	Interface Description	Interface Name	IP Address/Mask	VRF Table	Interface on C connected to A	GE0/1	10.10.1.1/24	VRF table for Sub a	Interface on C connected to B	GE0/2	10.10.2.1/24	VRF table for Sub b	Interface on C connected to Servers	GE0/3	10.10.3.1/24	VRF table for Servers	Interface on A connected to C	GE0/1	10.10.1.2/24	-	Interface on B connected to C	GE0/2	10.10.2.2/24	-
Interface Description	Interface Name	IP Address/Mask	VRF Table																						
Interface on C connected to A	GE0/1	10.10.1.1/24	VRF table for Sub a																						
Interface on C connected to B	GE0/2	10.10.2.1/24	VRF table for Sub b																						
Interface on C connected to Servers	GE0/3	10.10.3.1/24	VRF table for Servers

```

Common Errors

- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

7.4.2 Configuring a Multiprotocol VRF Table

Configuration Effect

- Provide the VPN service on a device.
- With BGP assistance, flexibly control the separation and access between VPNs.
- With BGP assistance, provide the VPN service in an IP/MPLS backbone network.
- Support IPv4 and IPv6 through address family configuration.

Notes

- No VRF table needs to be created if the device only forwards packets from one VPN or from the public network.
- If the device needs to forward public network packets and VPN packets or forward packets from multiple VPNs, VRF tables must be created to separate routes.
- In many cases, static or dynamic routes (RIP, OSPF, ISIS, and BGP) need to be added to VRF tables.

Configuration Steps

↳ Creating a VRF Table

- Mandatory.

- Create a VRF table for each VPN.

▾ Configuring an Address Family

- Mandatory.
- Enable the corresponding address family for each created VRF table.

▾ Configuring an RD

- Optional.
- When routing information needs to be advertised through BGP in the backbone network, BGP may select the best route for advertising if overlapping network addresses exist in different VPNs, which will make some VPNs fail to obtain corresponding routing information. To solve this problem, you can configure RDs for routes to enable BGP to make routing decisions based on these RDs, thus ensuring that each VPN can obtain corresponding routing information.

▾ Configuring an RT

- Optional.
- You can run the **route-target export** command to specify the attributes of the route to be advertised, and run the **route-target import** command to specify the attributes of the route to be received. You can also run the **route-target both** command to specify the export and import attributes.
- Run the **route-target** command in multiprotocol VRF mode or multiprotocol VRF address family mode.

▾ Binding an Interface and Adding the Direct Route and Host Route on the Interface to a VRF Table

- Mandatory.
- If the physical link for transmitting VPN packets is exclusively occupied by a VPN, bind the physical interface to the corresponding VRF table.
- If the physical link for transmitting VPN packets is shared by multiple VPNs, you need to create an independent logical link for each VPN, and bind the logical interface to the corresponding VRF table. A logical interface can be a subinterface or a VLAN interface.
- Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface.
- You must bind an interface to the corresponding multiprotocol VRF table before you configure the IPv4 or IPv6 address of the interface. If you bind the interface after its IPv4 or IPv6 address is configured, the address will be invalid.

▾ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

- Optional.
- If PBR is required for VRF table selection, run the **ip vrf receive** command on the interface to which PBR is applied, and import the direct route and host route on the interface to each VRF table available for choice.

Verification

- Check whether multiprotocol VRF tables are created correctly on the router and corresponding address families are enabled.

Related Commands

Creating a VRF Table

Command	vrf definition <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of the VRF table to be created. It cannot exceed 31 characters.
Command Mode	Global configuration mode
Usage Guide	After you run the command, the system will enter VRF mode.

Enabling the IPv4 Address Family

Command	address-family ipv4
Parameter Description	N/A
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv4 address family submode.

Enabling the IPv6 Address Family

Command	address-family ipv6
Parameter Description	N/A
Command Mode	VRF mode
Usage Guide	After you run the command, the system will enter VRF IPv6 address family submode.

Configuring an RD

Command	rd <i>rd_value</i>
Parameter Description	<p><i>rd_value</i> has the following three different parameter forms:</p> <p>(1) <i>rd_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295.</p> <p>(2) <i>rd_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535.</p> <p>(3) <i>rd_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.</p>

Command Mode	VRF configuration mode
Usage Guide	You cannot directly change the RD of an existing VRF table. You need to delete the VRF table first and then configure a new RD. A VRF table has only one RD. You cannot configure multiple RDs for one VRF table.

↘ Configuring an RT

Command	route-target { import export both } <i>rt_value</i>
Parameter Description	<i>rt_value</i> has the following three different parameter forms: (1) <i>rt_value</i> = as_num: nn as_num indicates the 2-byte number that identifies a public AS. nn is configurable in the range 0..4294967295. (2) <i>rt_value</i> = ip_addr: nn ip_addr must be a global IP address. nn is configurable in the range 0..65535. (3) <i>rt_value</i> = as4_num: nn as4_num indicates the 4-byte number that identifies a public AS. nn is configurable in the range 1..65535.
Command Mode	VRF configuration mode or VRF address family submode
Usage Guide	One VRF table can be configured with multiple import and export RT attributes.

↘ Binding an Interface

Command	vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Interface configuration mode
Usage Guide	By default, an interface does not belong to any VRF table. After an interface is bound to the corresponding VRF table, the direct route and host route on the interface will be automatically added to the VRF table. Before you bind an interface to a multiprotocol VRF table, enable an address family for the table. If you do not enable the IPv4 address family in advance, you cannot configure the IPv4 address and VRRP IPv4 address of the bound interface. If you do not enable the IPv6 address family in advance, you cannot configure the IPv6 address and VRRP IPv6 address of the bound interface. You must bind an interface to a multiprotocol VRF table before you configure the IPv4, IPv6, VRRP IPv4, and VRRP IPv6 addresses of the interface; otherwise, these addresses will be invalid and the IPv6 protocol on the interface will be disabled. If the IPv4 address family is deleted from the multiprotocol VRF table, the IPv4 and VRRP IPv4 addresses of all interfaces bound to the VRF table will be deleted, and the IPv4 static routes in the VRF table or next-hop routes are also deleted. If the IPv6 address family is deleted from the multiprotocol VRF table, the IPv6 and VRRP IPv6 addresses of all interfaces bound to the VRF table will be deleted, the IPv6 protocol on the interfaces will be disabled, and the IPv6 static routes in the VRF table or next-hop routes are also deleted.

➤ Adding the Direct Route and Host Route on an Interface to a VRF Table Without Binding the Interface

Command	<code>vrf receive vrf-name</code>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Interface configuration mode
Usage Guide	This command is used to add the host route and direct route on an interface to a VRF table. If you need to add the host route and direct route on an interface to multiple VRF tables, run the command multiple times. Different from the vrf forwarding command, the vrf receive command does not bind an interface to the corresponding VRF table. The interface is still a global interface and does not belong to any VRF table. The vrf forwarding and vrf receive commands are mutually exclusive on the same interface.

➤ Displaying the VRF Information on a Device

Command	<code>show vrf [brief detail ipv4 ipv6] [vrf-name]</code>
Parameter	brief : Displays brief information.
Description	detail : Displays detailed information. ipv4 : Displays the brief information of an IPv4 VRF table. ipv6 : Displays the brief information of an IPv6 VRF table. <i>vrf-name</i> : Indicates the name of a VRF table.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to display the information of a specified VRF table to check whether the VRF table is bound with the correct interface.

➤ Displaying the Routes in a VRF Table

Command	<code>show ip route vrf vrf-name</code>
Parameter	<i>vrf-name</i> : Indicates the name of a VRF table.
Description	
Command Mode	Privilege, global and interface configuration modes
Usage Guide	This command is used to check whether a specified VRF table contains corresponding routes.

Configuration Example

i The following example only describes VRF-related configuration on A1, B1, MCE1, and PE1. The configuration on A2, B2, MCE2, and PE2 is similar.

➤ VRF on CEs and PEs (MCE Application)

Scenario
Figure 7-5

VPN a and VPN b have independent address spaces.
VPN a runs RIP and VPN b runs OSPF.

Configuration Requirements

The routes in VPN a are separated from those in VPN b. A1 and A2 can access each other, and B1 and B2 can access each other.

Configuration Steps

- Connect MCE1 and A1 through RIP. Extend RIP routes on A1. On MCE1, create a VRF table for VPN a, bind the directly connected interface, and configure RIP routes.
- Connect MCE1 and B1 through OSPF. Extend OSPF routes on B1. On MCE1, create a VRF table for VPN b, bind the directly connected interface, and configure OSPF routes.
- Connect MCE1 and PE1 through BGP. On MCE1 and PE1, create a VRF table for each VPN, bind the VLAN interface, and configure BGP routes.
- Configure the physical link between MCE1 and PE1 in Trunk mode.
- In the VRF instance for VPN a on MCE1, redistribute the RIP routes to BGP, and redistribute the BGP routes to RIP.
- In the VRF instance for VPN b on MCE1, redistribute the OSPF routes to BGP, and redistribute the BGP routes to OSPF.

i Planning of interfaces and addresses:

Interface Description	Interface Name	IP Address/Mask	VRF Table
Physical interface on A1 connected to MCE1	GE0/1	10.10.1.2/24	-
Physical interface on B1 connected to MCE1	GE0/2	10.10.2.2/24	-

Verification	<ul style="list-style-type: none"> ● On A1, run the show ip route command to display the routes in VPN a. ● On B2, run the show ip route command to display the routes in VPN b. ● On MCE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b. ● On PE1, run the show ip route vrf vpna command to display the routes in VPN a, and run the show ip route vrf vpnb command to display the routes in VPN b.

Common Errors

- A multiprotocol VRF table is configured, but no address family is enabled.
- An interface is bound to a VRF table after the IP interface of the interface is configured.
- When a physical link is used to forward packets from multiple VPNs, the corresponding physical interface is bound to a VRF table.
- VPN routes are not introduced to BGP.

7.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the routes in a specified VRF table.	clear ip route vrf <i>vrf-name</i>

Displaying

Description	Command
Displays the information of a single-protocol VRF table.	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Displays the information of a multiprotocol VRF table.	show vrf [ipv4 ipv6 brief detail] [<i>vrf-name</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Displays the debugging information during the processes where a VRF table is created, an address family is enabled, and an interface is bound to the VRF table.	debug vrf
Prints the information of interface-related VRF operation debugging.	debug vrf interface

8 Configuring RIPng

8.1 Overview

RIP next generation (RIPng) is a unicast routing protocol that applies to IPv6 networks. RIPng-enabled routers exchange routing information to obtain routes to remote networks.

As an Interior Gateway Protocol (IGP), RIPng can run only within the autonomous system (AS) and is applicable to small-sized networks with routes no more than 16 hops.

Protocols and Standards

- RFC2080: Defines the RIPng.

8.2 Application

RIPng is generally used on some small-sized networks, such as office networks of small companies.

As shown in the following figure, the company builds an IPv6 network, on which all routers support IPv6. The network is small in size, but the workload is still heavy if the network is maintained manually. In this case, RIPng can be configured to adapt to topological changes of the small-sized network, which reduces the workload.

Figure 8-1

8.3 Features

Basic Concepts

↘ IGP and EGP

IGP runs within an AS. For example, RIPng is a type of IGP.

Exterior Gateway Protocol (EGP) runs between ASs. For example, BGP is a type of EGP.

Feature

Feature	Description
RIPng and RIP	RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.
Exchanging Routing Information	By exchanging routing information, RIPng-enabled devices can automatically obtain routes to a remote network and update routes in real time.
Routing Algorithm	RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.
Avoiding Route Loops	RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

8.3.1 RIPng and RIP

RIP applies to IPv4 networks. Two RIP versions are available, including RIPv1 and RIPv2.

RIPng is an extension of RIPv2 on the basis of IPv6. Both are similar in functions and configurations.

Working Principle

↳ RIPv2

RIPv2 packets are multicast. The multicast address is 224.0.0.9, and the UDP port ID is 520. RIPv2 can identify the subnet mask.

↳ RIPng

RIPng packets are multicast. The multicast address is FF02::9, the source address is FE80::/10, and the UDP port ID is 521. RIPng can identify the subnet mask.

 This chapter describes functions and configurations of RIPng. For details about RIPv2, see "Configuring RIP".

Related Configuration

↳ Enabling the RIPng Process

By default, the RIPng process is disabled.

Run the **ipv6 router rip** command to enable the RIPng process.

You must enable the RIPng process on a device; otherwise, all functions related to RIPng cannot take effect.

↳ Running RIPng on an Interface

By default, RIPng does not run on an interface.

Run the **ipv6 rip enable** command to run RIPng on an interface.

After RIPng runs on an interface, RIPng packets can be exchanged on the interface and RIPng can learn routes to the network segments directly connected to the device.

↘ Prohibiting an Interface from Sending or Receiving Packets

By default, a RIPng-enabled interface is allowed to send and receive RIPng packets.

Run the **passive-interface** command to prohibit an interface from sending RIPng packets.

8.3.2 Exchanging Routing Information

Compared with static routing, the dynamic routing protocol has a significant advantage, that is, by exchanging routing information, devices can automatically obtain routes to a remote network and update the routes in real time.

Working Principle

↘ Initialization

After RIPng is enabled on a router, the router sends a request packet to its neighbor router, requesting for all routing information, that is, the routing table. After receiving the request message, the neighbor router returns a response packet containing the local routing table. After receiving the response packet, the router updates the local routing table, and sends an update packet to the neighbor router, informing the neighbor router of the route update information. After receiving the update packet, the neighbor router updates the local routing table, and sends the update packet to other adjacent routers. After a series of updates, all routers can obtain and retain the latest routing information.

↘ Periodical Update

By default, periodical update is enabled for RIPng. Adjacent routers exchange complete routing information with each other every 30s (update timer), that is, the entire routing table is sent to neighbor routers.

- i** For every non-local route, if the route is not updated within 180s (invalid timer), the metric of the route is changed to 16 (unreachable). If the route is still not updated in the next 120s (flush timer), the route is deleted from the routing table.

↘ Default Route

In the routing table, a route to the destination network `::/0` is called default route.

The default route can be learned from a neighbor router, or sent to a neighbor router.

↘ Route Redistribution

For RIPng, other types of routes (such as direct routes, static routes, and routes of other routing protocols) are called external routes.

External routes (excluding the default route) can be redistributed to RIPng and advertised to neighbors.

↘ Route Filtering

Filtering conditions can be configured to limit the routing information exchanged between adjacent routers. Only the routing information that meets filtering conditions can be sent or received.

Related Configuration

↘ RIPng Timers

By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Run the **timers basic** command to modify durations of RIPng timers.

Increasing the duration of the flush timer can reduce the route flapping. Decreasing the duration of the flush timer helps accelerate route convergence.

The durations of RIPng timers must be consistent on adjacent routers. Unless otherwise required, you are advised not to modify the RIPng timers.

↘ Default Route

Run the **ipv6 rip default-information** command to advertise the default route to neighbors on an interface.

↘ Route Redistribution

Run the **redistribute** command to redistribute external routes (excluding the default route) to RIPng and advertise them to neighbors.

↘ Route Filtering

Run the **distribute-list out** command to set filtering rules to limit the routing information sent by the device.

Run the **distribute-list in** command to set filtering rules to limit the routing information received by the device.

8.3.3 Routing Algorithm

RIPng is a protocol based on the distance-vector algorithm. It uses the vector addition method to compute the routing information.

Working Principle

↘ Distance-Vector Algorithm

RIPng is a protocol based on the distance-vector algorithm. The distance-vector algorithm treats a route as a vector that consists of the destination network and distance (metric). The router obtains a route from its neighbor and adds the distance vector from itself to the neighbor to the route to form its own route.

RIPng uses the hop count to evaluate the distance (metric) to the destination network. By default, the hop count from a router to its directly connected network is 0, the hop count from a router to a network that can be reached through a router is 1, and so on. That is, the metric is equal to the number of routers from the local network to the destination network. To restrict the convergence time, RIPng stipulates that the metric must be an integer between 0 and 15. If the metric is equal to or greater than 16, the destination network or host is unreachable. For this reason, RIPng cannot be applied to a large-scale network. As shown in the following figure, Router A is connected to the network 2::/64. Router B obtains the route (2::/64, 0) from Router A and adds the metric 1 to the route to obtain its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-2

↘ **Selecting the Optimum Route**

RIPng selects an optimum route based on the following principle: If multiple routes to the same destination network is available, a router preferentially selects the route with the smallest metric.

As shown in the following figure, Router A is connected to the network 2::/64. Router C obtains the route (2::/64, 0) from Router A and the route (2::/64, 1) from Router B. Router C will select the route that is obtained from Router A and add metric 1 to this route to form its own route (2::/64, 1), and the next hop points to Router A.

Figure 8-3

i When routes coming from different sources exist on a router, the route with the smaller distance is preferentially selected.

Route Source	Default Distance
Directly-connected network	0
Static route	1
OSPF route	110
IS-IS route	115
RIPng route	120
Unreachable route	255

Related Configuration

↘ **Modifying the Distance**

By default, the distance of a RIPng route is 120.

Run the **distance** command to modify the distance of a RIPng route.

✚ Modifying the Metric

For a RIPng route that is proactively discovered by a device, the default metric is equal to the number of hops from the local network to the destination network. The metric offset of the interface is 1.

For a RIPng router that is manually configured (default route or redistributed route), the default metric is 1.

Run the **ipv6 rip metric-offset** command to modify the metric offset of the interface.

Run the **default-metric** command to modify the default metric of an external route (redistributed route).

Run the **redistribute** command to modify the metric of an external route (redistributed route) when advertising this route.

Run the **ipv6 rip default-information** command to modify the metric of a default route when advertising the default route.

8.3.4 Avoiding Route Loops

RIPng uses functions, such as split horizon and poison reverse, to avoid route loops.

Working Principle

✚ Route Loop

A RIPng route loop occurs due to inherent defects of the distance-vector algorithm.

As shown in the following figure, Router A is connected to the network 2::/64, and sends an update packet every 30s. Router B receives the route to 2::/64 from Router A every 30s. If Router A is disconnected from 2::/64, the route to 2::/64 will be deleted from the routing table on Router A. Next time, the update packet sent by Router A no longer contains this route. As Router B does not receive an update packet related to 2::/64, Router B determines that the route to 2::/64 is valid within 180s and uses the update packet to send this route to Router A. As the route to 2::/64 does not exist on Router A, the route learned from Router B is added to the routing table. Router B determines that data can reach 2::/64 through Router A, and Router A determines that data can reach 2::/64 through Router B. In this way, a route loop is formed.

Figure 8-4

✚ Split Horizon

Split horizon can prevent route loops. After split horizon is enabled, a route received on this interface will not be sent out from this interface.

As shown in the following figure, after split horizon is enabled on Router B, Router B will not send the route to 2::/64 back to Router A. Router B will learn 180s later that 2::/64 is not reachable.

Figure 8-5

↳ Poison Reverse

Poison reverse can also prevent route loops. Compared with split horizon, poison reverse is more reliable, but brings more protocol packets, which makes network congestion more severe.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric of this router will be changed to 16 (unreachable).

As shown in the following figure, after poison reverse is enabled on Router A, if Router A detects a disconnection from 2::/64, Router A will not delete the route to 2::/64. Instead, Router A changes the number of hops to 16, and advertises the route through the update packet. On receiving the update packet, Router B learns that 2::/64 is not reachable.

Figure 8-6

Related Configuration

↳ Split Horizon

By default, split horizon is enabled.

Run the **no split-horizon** command to disable split horizon.

↳ Poison Reverse

By default, poison reverse is disabled.

Run the **split-horizon poisoned-reverse** command to enable poison reverse. (After poison reverse is enabled, split horizon is automatically disabled.)

8.4 Configuration

Configuration	Related Commands	
Configuring RIPng Basic Functions	 (Mandatory) It is used to build a RIPng routing domain.	
	ipv6 router rip	Enables a RIPng routing process and enters routing process configuration mode.
	ipv6 rip enable	Runs RIPng on an interface.
	split-horizon	Enables split horizon or poison reverse.
	passive-interface	Configures a passive interface.
Advertising the Default Route or External Routes	 Optional.	
	ipv6 rip default-information	Advertise the default route to neighbors on an interface.
	redistribute	Redistributes routes and advertising external routes to neighbors.
Setting Route Filtering Rules	 Optional.	
	distribute-list in	Filters the received RIPng routing information.
	distribute-list out	Filters the sent RIPng routing information.
Modifying Route Selection Parameters	 Optional.	
	distance	Modifies the administrative distance of a RIPng route.
	ipv6 rip metric-offset	Modifies the metric offset on an interface.
	default-metric	Configure the default metric for route redistribution.
Modifying Timers	 Optional.	
	timers	Modifies the update timer, invalid timer, and flush timer of RIPng.

8.4.1 Configuring RIPng Basic Functions

Configuration Effect

- Build a RIPng routing domain on the network.
- Routers in the domain obtain routes to a remote network through RIPng.

Notes

- IPv6 addresses must be configured.
- IPv6 unicast routes must be enabled.

Configuration Steps

▾ Enabling a RIPng Routing Process

- Mandatory.
- Unless otherwise required, perform this configuration on every router in the RIPng routing domain.

↳ Running RIPng on an Interface

- Mandatory.
- Unless otherwise required, perform this configuration on every interconnected interface of routers in the RIPng routing domain.

↳ Enabling Split Horizon or Poison Reverse

- By default, split horizon is enabled and poison reverse is disabled.
- Unless otherwise required, enable split horizon on every interface connected to the broadcast network, such as the Ethernet. (Retain the default setting.)
- Unless otherwise required, enable split horizon on every interface connected to the point-to-point (P2P) network, such as the PPP and HDLC. (Retain the default setting.)
- It is recommended that split horizon and poison reverse be disabled on an interface connected to a non-broadcast multi-access network, such as FR and X.25; otherwise, some devices cannot learn the complete routing information.
- If the secondary IP address is configured for an interface connected to a non-broadcast, it is recommended that split horizon and poison reverse be disabled.

↳ Configuring a Passive Interface

- This configuration is recommended.
- Use the passive interface to set the boundary of the RIPng routing domain. The network segment of the passive interface belongs to the RIPng routing domain, but RIPng packets cannot be sent over the passive interface.
- If RIPng routes need to be exchanged on an interface (such as the router interconnect interface) in the RIPng routing domain, this interface cannot be configured as a passive interface.

Verification

- Check the routing table on a router to verify that the route to a remote network can be obtained through RIPng.

Related Commands

↳ Enabling a RIPng Routing Process

Command	ipv6 router rip
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to create a RIPng routing process and enter routing process configuration mode.

↳ Running RIPng on an Interface

Command	ipv6 rip enable
----------------	------------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The configuration for running the RIPng on an interface is different from that of RIPv2. In RIPv2, the network command is configured in routing process configuration mode to define an IP address range. If the IP address of an interface belongs to this IP address range, RIP automatically runs on this interface.

↳ Enabling Split Horizon

Command	split-horizon [poisoned-reverse]
Parameter Description	poisoned-reverse: Indicates that the split horizon function contains the poison reverse function.
Command Mode	Routing process configuration mode
Usage Guide	Run the show ipv6 rip command to check whether split horizon is enabled. The configuration is different from that of RIPv2. In RIPv2, the split horizon function is configured in interface configuration mode.

↳ Configuring a Passive Interface

Command	passive-interface { default interface-type interface-num }
Parameter Description	default: Indicates all interfaces. interface-type interface-num: Specifies an interface.
Command Mode	Routing process configuration mode
Usage Guide	First, run the passive-interface default command to configure all interfaces as passive interfaces. Then, run the no passive-interface interface-type interface-num command so that the interfaces used for interconnection between routers in the domain are not passive interface.

↳ Displaying the IP Routing Table

Command	show ipv6 route
Parameter Description	N/A
Command Mode	Privileged EXEC mode or global configuration mode
Usage Guide	Check whether the routing table contains any route to a remote network that is learned through RIPng.

Configuration Example

↳ Building a RIPng Routing Domain

<p>Scenario Figure 8-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IPv6 addresses on all routers. ● Enable RIPng on all routers.
<p>A</p>	<pre>A# configure terminal Enter configuration commands, one per line. End with CNTL/Z. A(config)# ipv6 router rip A(config-router)# exit A(config)# interface GigabitEthernet 0/0 A(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::1/32 A(config-if-GigabitEthernet 0/0)# ipv6 rip enable</pre>
<p>B</p>	<pre>B# configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)# ipv6 router rip B(config-router)# exit B(config)# interface GigabitEthernet 0/0 B(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::2/32 B(config-if-GigabitEthernet 0/0)# ipv6 rip enable</pre>
<p>C</p>	<pre>C# configure terminal Enter configuration commands, one per line. End with CNTL/Z. C(config)# ipv6 router rip C(config-router)# exit C(config)# interface GigabitEthernet 0/0 C(config-if-GigabitEthernet 0/0)#</pre>

	<pre>C(config-if-GigabitEthernet 0/0)# ipv6 address 2001:db8::3/32 C(config-if-GigabitEthernet 0/0)# ipv6 rip enable C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ipv6 address 2::1/64 C(config-if-GigabitEthernet 0/1)# ipv6 rip enable</pre>
Verification	<p>Check the routing tables on Router A, Router B, and Router C. The routing tables should contain routes to a remote network that are learned through RIPng.</p>
A	<pre>A# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::1/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:E7CE/128 via GigabitEthernet 0/0, local host</pre>
B	<pre>B# show ipv6 route IPv6 routing table name - Default - 6 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2</pre>

	<pre> IA - Inter area R 2::/64 [120/2] via FE80::2D0:F8FF:FEFB:D521, GigabitEthernet 0/0 C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::2/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C9BA/128 via GigabitEthernet 0/0, local host </pre>
C	<pre> Nodexon# show ipv6 route IPv6 routing table name - Default - 9 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS, V - Overflow route N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 2::/64 via GigabitEthernet 0/1, directly connected L 2::2/128 via GigabitEthernet 0/1, local host C 2001:DB8::/32 via GigabitEthernet 0/0, directly connected L 2001:DB8::3/128 via GigabitEthernet 0/0, local host C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:D521/128 via GigabitEthernet 0/1, local host </pre>

Common Errors

- The IPv6 address is not configured on an interface.
- The interface used for interconnection between devices is configured as a passive interface.

8.4.2 Advertising the Default Route or External Routes

Configuration Effect

- In the RIPng domain, introduce a unicast route of another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.
- In the RIPng domain, inject a default route to another AS so that the unicast routing service to this AS can be provided for users in the RIPng domain.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

▾ Configuring External Route Redistribution

- Optional.
- Perform this configuration if external routes of the RIPng domain should be introduced to the AS border router (ASBR).

▾ Generating a Default Route

- Optional.
- Perform this configuration if the default route should be introduced to an ASBR so that other routers in the RIPng domain access other AS domains through this ASBR by default.

Verification

- Run the **show ipv6 route rip** command on a non-ASBR to check whether the external routes of the domain and default route have been loaded.

Related Commands

▾ Advertising the Default Route to Neighbors on an Interface

Command	<code>ipv6 rip default-information { only originate } [metric <i>metric-value</i>]</code>
Parameter Description	<p>only: Advertises only IPv6 default route.</p> <p>originate: Advertises the IPv6 default route and other routes.</p> <p>metric <i>metric-value</i>: Indicates the metric of the default route. The value ranges from 1 to 15. The default value is 1.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>After this command is configured on the interface, an IPv6 default route is advertised to the external devices through this interface, but the route itself is not added to the route forwarding table or the device and the RIPng route database.</p> <p>To prevent occurrence of a route loop, once this command is configured on an interface, RIPng refuses to receive the default route updates advertised by neighbors.</p>

↘ Redistributing Routes and Advertising External Routes to Neighbors

Command	<code>redistribute { bgp connected isis [area-tag] ospf process-id static } [metric metric-value route-map route-map-name]</code>
Parameter Description	<p>bgp: Indicates redistribution from BGP.</p> <p>Connected: Indicates redistribution from direct routes.</p> <p>isis [area-tag]: Indicates redistribution from IS-IS. <i>area-tag</i> indicates the IS-IS process ID.</p> <p>ospf process-id: Indicates redistribution from OSPF. <i>process-id</i> indicates the OSPF process ID. The value ranges from 1 to 65535.</p> <p>static: Indicates redistribution from static routes.</p> <p>metric metric-value: Sets the metric of the route redistributed to the RIPng domain.</p> <p>route-map route-map-name: Sets the redistribution filtering rules.</p>
Command Mode	Routing process configuration mode
Usage Guide	During route redistribution, it is not necessary to convert the metric of one routing protocol to the metric of another routing protocol because different routing protocols use completely different metric measurement methods. RIP measures the metric based on the hop count, and OSPF measures the metric based on the bandwidth. Therefore, the computed metrics cannot be compared with each other.

Configuration Example

Scenario	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On Router B, configure redistribution of static routes. ● On the GE0/1 interface of Router A, configure advertisement of the default route.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ipv6 rip default-information originate</pre>
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# redistribute static</pre>
Verification	<ul style="list-style-type: none"> ● Check the routing tables on Router A and Router B, and confirm that Router A can learn the route 3001:10:10::/64, and Router B can learn the default route ::/0.

<p>A</p>	<pre>A# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 3001:10:10::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>
<p>B</p>	<pre>B# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R ::/0 [120/2] via FE80::21A:A9FF:FE41:5B06, GigabitEthernet 0/1</pre>

8.4.3 Setting Route Filtering Rules

Configuration Effect

- Routes that do not meet filtering criteria cannot be loaded to the routing table, or advertised to neighbors. In this way, users within the network can be prevented from accessing specified destination networks.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

📌 Filtering the Received RIP Routing Information

- To refuse receiving some specified routes, you can configure the route distribution control list to process all the received route update packets. If no interface is specified, route update packets received on all interfaces will be processed.

Filtering the Sent RIP Routing Information

- If this command does not contain any optional parameter, route update advertisement control takes effect on all interfaces. If the command contains the interface parameter, route update advertisement control takes effect only on the specified interface. If the command contains other routing process parameters, route update advertisement control takes effect only on the specified routing process.

Verification

- Run the **show ipv6 route rip** command to check that the routes that have been filtered out are not loaded to the routing table.

Related Commands

Command	distribute-list prefix-list <i>prefix-list-name</i> { in out } [<i>interface-type interface-name</i>]
Parameter	prefix-list <i>prefix-list-name</i> : Indicates the name of the prefix list, which is used to filter routes.
Description	in out : Specifies update routes (received or sent routes) that are filtered. <i>interface-type interface-name</i> : Indicates that the distribution list is applied to the specified interface.
Command Mode	Routing process configuration mode
Usage Guide	N/A

Configuration Example

Scenario	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On router A, configure route filtering.
A	<pre>A# configure terminal A(config)# ipv6 prefix-list hello permit 4001::/64 A(config)# ipv6 router rip A(config-router)# distribute-list prefix-list hello in</pre>
Verification	<ul style="list-style-type: none"> ● Check that Router A can learn only the route to 4001::/64.

A	<pre>A# show ipv6 route rip IPv6 routing table name - Default - 17 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area R 4001::/64 [120/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>
----------	---

8.4.4 Modifying Route Selection Parameters

Configuration Effect

- Change the RIPng routes to enable the traffic pass through specified nodes or avoid passing through specified nodes.
- Change the sequence that a router selects various types of routes so as to change the priorities of RIPng routes.

Notes

- The RIPng basic functions must be configured.

Configuration Steps

▾ Modifying the Administrative Distance of a RIPng Route

- Optional.
- Perform this configuration if you wish to change the priorities of RIPng routes on a router that runs multiple unicast routing protocols.

▾ Modifying the Metric Offset on an Interface

- Optional.
- Unless otherwise required, perform this configuration on a router where the metrics of routes need to be adjusted.

▾ Configuring the Default Metric of an External Route Redistributed to RIPng

- Optional.
- Unless otherwise required, perform this configuration on an ASBR to which external routes are introduced.

Verification

- Run the **show ipv6 rip** command to display the administrative distance of RIPng routes.
- Run the **show ipv6 rip data** command to display the metrics of external routes redistributed to RIPng.

Related Commands

Modifying the Administrative Distance of a RIPng Route

Command	<code>distance distance</code>
Parameter Description	<i>distance</i> : Sets the administrative distance of a RIPng route. The value is an integer ranging from 1 to 254.
Command Mode	Routing process configuration mode
Usage Guide	Run this command to set the administrative distance of a RIPng route.

Modifying the Metric Offset on an Interface

Command	<code>ipv6 rip metric-offset value</code>
Parameter Description	<i>value</i> : Indicates the interface metric offset. The value ranges from 1 to 16.
Command Mode	Routing process configuration mode
Usage Guide	Before a route is added to the routing table, the metric of the route must be added with the metric offset set on the interface. You can control the use of a route by setting the interface metric offset.

Configuring the Default Metric of an External Route Redistributed to RIPng

Command	<code>default-metric metric</code>
Parameter Description	<i>metric</i> : Indicates the default metric. The valid value ranges from 1 to 16. If the value is equal to or greater than 16, the NXOS determines that this route is unreachable.
Command Mode	Global configuration mode
Usage Guide	If the metric is not specified during redistribution of a routing protocol process, RIPng uses the metric defined by the default-metric command. If the metric is specified, the metric defined by the default-metric command is overwritten by the specified metric. If this command is not configured, the value of default-metric is 1.

Configuration Example

Modifying the Administrative Distance of a RIPng Route

Scenario	<p>The diagram illustrates a network topology with two routers, A and B, connected via their GE 0/1 interfaces. Router A has a loopback interface with address 2001::1/64. Router B has a loopback interface with address 3001::1/64. The link between A and B is labeled with 2001::1/64 and 2001::2/64.</p>
-----------------	---

Configuration Steps	<ul style="list-style-type: none"> ● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On Router A, set the administrative distance of a RIPng route to 160.
	<pre>A# configure terminal A(config)# ipv6 router rip A(config-router)# distance 160</pre>
Verification	<ul style="list-style-type: none"> ● On Router A, check whether the administrative distance of a RIPng route is 160.
	<pre>A# show ipv6 route rip in 3001::/64 R 3001::/64 [160/2] via FE80::2D0:F8FF:FE22:334A, GigabitEthernet 0/1</pre>

8.4.5 Modifying Timers

Configuration Effect

- Change the duration of RIPng timers to accelerate or slow down the change of the protocol state or occurrence of an event.

Notes

- The RIPng basic functions must be configured.
- Modifying the protocol control parameters may result in protocol running failures. Therefore, you are advised not to modify the timers.

Configuration Steps

✚ Modifying the Update Timer, Invalid Timer, and Flush Timer

- Mandatory.
- Unless otherwise required, perform this configuration on a router where RIPng timers need to be modified.

Verification

- Run the **show ipv6 rip** command to display settings of timers.

Related Commands

Command	timers update invalid flush
Parameter Description	<p><i>Update</i>: Indicates the route update time in second. It defines the interval at which the device sends the route update packet. Each time an update packet is received, the invalid timer and flush timer are reset. By default, a route update packet is sent every 30s.</p> <p><i>Invalid</i>: Indicates the route invalid time in second, counted from the last time when a valid update packet is received. It defines the time after which the route in the routing list becomes invalid because the route is not</p>

	<p>updated. The duration of the invalid timer must be at least three times the duration of the update timer. If no update packet is received before the invalid timer expires, the corresponding route enters the invalid state. If the update packet is received before the invalid timer expires, the timer is reset. The default duration of the invalid timer is 180s.</p> <p><i>Flush</i>: Indicates the route flushing time in second, counted from the time when the RIPng route enters the invalid state. When the flush timer expires, the route in the invalid state will be deleted from the routing table. The default duration of the flush timer is 120s.</p>
Command Mode	Routing process configuration mode
Usage Guide	By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Configuration Example

Scenario	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the interface IPv6 addresses on all routers. (Omitted) ● Configure the RIPng basic functions on all routers. (Omitted) ● On Router A, configure the update timer, invalid timer, and flush timer.
B	<pre>B# configure terminal B(config)# ipv6 router rip B(config-router)# timers 10 30 90</pre>
Verification	<ul style="list-style-type: none"> ● On Router B, check the settings of RIPng timers.

```

B
B# show ipv6 rip

Routing Protocol is "RIPng"

  Sending updates every 10 seconds with +/-50%, next due in 12 seconds

  Timeout after 30 seconds, garbage collect after 90 seconds

  Outgoing update filter list for all interface is: not set

  Incoming update filter list for all interface is: not set

  Default redistribution metric is 1

  Default distance is 120

  Redistribution:

    Redistributing protocol connected

  Default version control:  send version 1, receive version 1

  Interface                Send    Recv

    GigabitEthernet 0/1    1      1

  Routing Information Sources:

    Gateway: fe80::2d0:f8ff:fe22:334a  Distance: 120

  Last Update: 00:00:02  Bad Packets: 0  Bad Routes: 0
    
```

Common Errors

- Settings of RIPng timers on devices connected to the same network are inconsistent. Consequently, routes cannot be learned properly.

8.5 Monitoring

Displaying

Description	Command
Displays information about the RIPng process.	show ipv6 rip
Displays the RIPng routing table.	show ipv6 rip database

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs RIPng.	debug ipv6 rip [interface <i>interface-type interface-num</i> nsm restart

9 Managing Routes

9.1 Overview

The network service module (NSM) manages the routing table, consolidates routes sent by various routing protocols, and selects and sends preferred routes to the routing table. Routes discovered by various routing protocols are stored in the routing table. These routes are generally classified by source into three types:

- Direct route: It is the route discovered by a link-layer protocol and is also called interface route.
- Static route: It is manually configured by the network administrator. A static route is easy to configure and less demanding on the system, and therefore applicable to a small-sized network that is stable and has a simple topology. However, when the network topology changes, the static route must be manually reconfigured and cannot automatically adapt to the topological changes.
- Dynamic route: It is the route discovered by a dynamic routing protocol.

9.2 Applications

Application	Description
Basic Functions of the Static Route	Manually configure a route.
Floating Static Route	Configure a standby route in the multipath scenario.
Load Balancing Static Route	Configure load balancing static routes in the multipath scenario.
Correlation of Static Routes with BFD	Use the Bidirectional Forwarding Detection (BFD) function to test whether the next hop of a static route is reachable.
Fast Reroute of Static Routes	Use the fast reroute function to improve the switching performance in the multipath scenario.

9.2.1 Basic Functions of the Static Route

Scenario

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

As shown in Figure 9-1, to implement interworking between PC 1, PC 2, and PC 3, you can configure static routes on R 1, R 2, and R 3.

- On R 1, configure a route to the network segment of PC 2 through R 2, and a route to the network segment of PC 3 through R 3.
- On R 2, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 3 through R 3.

- On R 3, configure a route to the network segment of PC 1 through R 1, and a route to the network segment of PC 2 through R 2.

Figure 9-1

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

9.2.2 Floating Static Route

Scenario

If no dynamic routing protocol is configured, you can configure floating static routes to implement dynamic switching of routes to prevent communication interruption caused by the network connection failures.

As shown in Figure 9-2, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3. Normally, packets are forwarded on a path with a small administrative distance. If a link on this path is down, the route is automatically switched to the path with a large administrative distance.

- On R1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2).
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2).

Figure 9-2

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.

9.2.3 Load Balancing Static Route

Scenario

If there are multiple paths to the same destination, you can configure load balancing routes. Unlike floating routes, the administrative distances of load balancing routes are the same. Packets are distributed among these routes based on the balanced forwarding policy.

As shown in Figure 9-3, load balancing routes are configured respectively on R 1 and R 3 so that packets sent to the network segment of PC 3 or PC 1 are balanced between two routes, including a route through R 2 and a route through R 4.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 2 and a route through R 4.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 2 and a route through R 4.

Figure 9-3

Remarks	<p>On the switch, the load is balanced based on the source IP address by default. Run the aggregateport load-balance command to configure the load balancing mode of ECMP route.</p> <p>On a router, run the ip ref load-sharing original command to configure the load balancing policy of IPv4 routes, or the ipv6 ref load-sharing original command to configure the load balancing policy of IPv6 routes.</p>
----------------	--

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, R 3, and R 4.
- Configure the load balancing policy on R 1 and R 3.

9.2.4 Correlation of Static Routes with Track, BFD or ARP

Scenario

When the floating static routes or load balancing static routes are configured, the static routes may fail to sense the route failures if the line is faulty but the interface status is normal. To resolve this problem, the device needs to check whether the next hop of a static route is reachable. If the next hop is not reachable, the device can switch the traffic to the standby route. You can use the Track, BFD or ARP function to check whether the next hop of a static route is reachable. The following scenario takes BFD as an example.

! You can use only one of the Track and BFD functions at a time.

As shown in Figure 9-4, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure a floating static route respectively on R 1 and R 3, and correlate static routes with BFD.

- On R 1, configure two routes to the network segment of PC 3, including a route through R 3 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.3 is reachable, and on the second route to check whether the next hop 1.1.12.2 is reachable.
- On R 3, configure two routes to the network segment of PC 1, including a route through R 1 (default distance = 1) and a route through R 2 (default distance = 2). BFD is enabled on the first route to check whether the next hop 1.1.13.1 is reachable, and on the second route to check whether the next hop 1.1.23.2 is reachable.

Figure 9-4

Deployment

- Configure the address and subnet mask of each interface.
- Configure the BFD parameters on each interface.
- Configure static routes and correlate these static routes with BFD on R 1, R 2, and R 3.

9.2.5 Fast Reroute of Static Routes

Scenario

To accelerate route switching and shorten the communication interruption time when no dynamic routing protocol is configured, you can either correlate static routes with Track or BFD to check whether the next hop is reachable. In addition, you can or configure fast reroute to further improve the convergence performance.

As shown in Figure 9-5, to prevent communication interruption caused by a line failure between R 1 and R 3, you can configure static fast reroute respectively on R 1 and R 3. Normally, packets are forwarded on the path between R 1 and R 3. When the link on this route is down, packets are automatically rerouted to R 2.

- On R 1, configure a route with the exit interface set to Gi0/3 and the next hop set to 1.1.13.3, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.12.2.
- On R 3, configure a route with the exit interface set to Gi0/1 and the next hop set to 1.1.13.1, and a standby route with the exit interface set to Gi0/2 and the next hop set to 1.1.23.2.

Figure 9-5

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R 1, R 2, and R 3.
- Configure static fast reroute on R 1 and R 3.

9.3 Features

Feature	Description
Route Computation	Generate a valid route on a device.
Optimal Route Selection	Select an optimal route to forward packets.
Default Route	Forward all packets and help reduce the size of a routing table.
Route Reliability	Quickly detect a route failure and recover communication.

9.3.1 Route Computation

Routing Function

Routing functions are classified into IPv4 and IPv6 routing functions. If the routing functions are disabled, a device is equivalent to a host and cannot forward routes.

Dynamic Route

A dynamic routing protocol learns remote routes and dynamically updates routes by exchanging routes with neighbors. If a neighbor is the next hop of a route and this neighbor fails, the route fails as well.

Static Route

On a network with a simple topology, you can configure only static routes to implement network interworking. Appropriate configuration and use of static routes can improve the network performance and guarantee the bandwidth for important network applications.

Whether a static route is active is computed based on the status of the local interface. When the exit interface of a static route is located at layer 3 (L3) and is in Up status (the link status is Up and the IP address is configured), this route is active and can be used for packet forwarding.

A static route can go across VPN routing & forwarding (VRF) instances. The next hop or exit interface of a static route of VRF 1 can be configured on VRF 2.

9.3.2 Optimal Route Selection

Administrative Distance

When multiple routing protocols generate routes to the same destination, the priorities of these routes can be determined based on the administrative distance. A smaller administrative distance indicates a higher priority.

Equal-Cost Route

If multiple routes to the same destination have different next hops but the same administrative distance, these routes are mutually equal-cost routes. Packets are distributed among these routes to implement load balancing based on the balanced forwarding policy.

On a specific device, the total number of equal-cost routes is limited. Routes beyond the limit do not participate in packet forwarding.

Floating Route

If multiple routes to the same destination have different next hops and different administrative distances, these routes are mutually floating routes. The route with the smallest administrative distance will be first selected for packet forwarding. If this route fails, a route with a larger administrative distance is further selected for forwarding, thus preventing communication interruption caused by a network line failure.

9.3.3 Default Route

In the forwarding routing table, the route with the destination network segment 0.0.0.0 and the subnet mask 0.0.0.0 is the default route. Packets that cannot be forwarded by other routes will be forwarded by the default route. The default route can be statically configured or generated by a dynamic routing protocol.

Default Gateway

On a L2 switch, the **ip default gateway** command is configured to generate a default route.

Static Default Route

On a L3 switch, a static route with the network segment 0.0.0.0 and the subnet mask 0.0.0.0 is configured to generate the default route.

Default Network

The default network is configured to generate a default route. If the **ip default-network** command is configured to specify a network (a classful network, such as a Class A, B, or C network), and this network exists in the routing table, the router will use this network as the default network and the next hop of this network is the default gateway. As the network specified by the **ip default-network** command is a classful one, if this command is used to identify a subnet in a classful network, the router automatically generates a static route of the classful network instead of any default route.

9.3.4 Route Reliability

When a device on a network is faulty, some routes become unreachable, resulting in traffic interruption. If connectivity of the next hop can be detected in real time, the route can be re-computed when a fault occurs, or traffic can be switched over to the standby route.

Correlation with Track

A track object is an abstract concept. It can be used to trace whether an IP address is reachable or whether an interface is up. If a dynamic routing protocol or a static route is correlated with the Track function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

Correlation with BFD

The BFD protocol provides a light-load and fast method for detecting the connectivity of the forwarding path between two adjacent routers. If a dynamic routing protocol or a static route is correlated with the BFD function, the dynamic routing protocol or the static route can quickly learn whether the next hop is reachable so as to respond quickly.

 The detection performance of BFD is better than that of Track.

Fast Reroute

Fast reroute provides a standby route. When a dynamic routing protocol or a static route detects that the next hop is unreachable, it immediately switches traffic over to the standby route to recovery communication.

9.4 Configuration

Configuration Item	Description and Command	
Configuring a Static Route	 (Mandatory) It is used to configure a static route entry.	
	ip route	Configures an IPv4 static route.
	ipv6 route	Configures an IPv6 static route.
Configuring a Default Route	 (Optional) It is used to configure the default gateway.	
	ip default gateway	Configures an IPv4 default gateway on a L2 device.

Configuration Item	Description and Command	
	ipv6 default gateway	Configures an IPv6 default gateway on a L2 device.
	ip route 0.0.0.0 0.0.0.0 gateway	Configures an IPv4 default gateway on a L3 device.
	ipv6 route ::/0 ipv6-gateway	Configures an IPv6 default gateway on a L3 device.
	ip default network	Configures an IPv4 default network on a L3 device.
Configuring Route Limitations	 (Optional) It is used to limit the number of equal-cost routes and number of static routes, or disable routing.	
	maximum-paths	Configures the maximum number of equal-cost routes.
	ip static route-limit	Configures the maximum number of IPv4 static routes.
	ipv6 static route-limit	Configures the maximum number of IPv6 static routes.
	no ip routing	Disables IPv4 routing.
	noipv6 unicast-routing	Disables IPv6 routing.
	no ip route static inter-vrf	Prohibits static routing across VRFs.
Correlating a Static Route with BFD	 (Optional) It is used to correlate a static route with BFD.	
	ip route static bfd	Correlates an IPv4 static route with BFD.
	ipv6 route static bfd	Correlates an IPv6 static route with BFD.
Configure Static Fast Reroute	 (Optional) It is used to configure static fast reroute.	
	route-map	Configures a route map.
	set fast-reroute backup-nexthop	Configures the standby interface and standby next hop for fast reroute.
	ip fast-reroute	Configures static fast reroute.

9.4.1 Configuring a Static Route

Configuration Effect

- Generate a static route in the routing table. Use the static route to forward packets to a remote network.

Notes

- Static routes cannot be configured on a L2 switch.

- If the **no ip routing** command is configured on a L3 switch, you cannot configure IPv4 static routes on this switch, and existing IPv4 static routes will also be deleted. Before the device is restarted, reconfiguring the **ip routing** command can recover the deleted IPv4 static routes. After the device is restarted, deleted IPv4 static routes cannot be recovered.
- If the **no ipv6 unicast-routing** command is configured on a L3 switch, you cannot configure IPv6 static routes on this switch, and existing IPv6 static routes will also be deleted. Before the device is restarted, reconfiguring the **ipv6 unicast-routing** command can recover the deleted IPv6 static routes. After the device is restarted, deleted IPv6 static routes cannot be recovered.
- To correlate a static route with the Track function, you must run the **track** command to configure a track object.

Configuration Steps

▾ Configuring a Static IPv4 Route

Configure the following command on an IPv4-enabled router.

Command	ip route [vrf <i>vrf_name</i>] <i>network</i> / <i>net-mask</i> { <i>ip-address</i> <i>interface</i> [<i>ip-address</i>]} [<i>distance</i>] [tag <i>tag</i>] [permanent track <i>object-number</i>] [weight <i>number</i>] [description <i>description-text</i>] [disabled enabled]	
Parameter Description	<i>vrf vrf_name</i>	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by default.
	<i>network</i>	Indicates the address of the destination network.
	<i>net-mask</i>	Indicates the mask of the destination network.
	<i>ip-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	<i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	track <i>object-number</i>	(Optional) Indicates correlation with Track. <i>object-number</i> indicates the ID of the track object. By default, the static route is not correlated with the Track function.
	weight <i>number</i>	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
disabled/enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.	
Defaults	By default, no static route is configured.	
Command	Global configuration mode	

Mode	
Usage Guide	<p>The simplest configuration of this command is ip route networknet-maskip-address.</p> <p>If the static route is correlated with Track and the down status of the trace object is detected, the static route is not active and does not participate in packet forwarding.</p> <p>If the static route is correlated with ARP, but no ARP information is detected, the static route is not active and does not participate in packet forwarding.</p>

📌 **Configuring an IPv6 Static Route**

Configure the following command on an IPv6-enabled router.

Command	ipv6 route [<i>vrf vrf-name</i>] <i>ipv6-prefix/prefix-length</i> { <i>ipv6-address</i> [nexthop-vrf { <i>vrf-name1</i> default }] <i>interface</i> [<i>ipv6-address</i> [nexthop-vrf { <i>vrf-name1</i> default }]] } [<i>distance</i>] [weight <i>number</i>] [description <i>description-text</i>]	
Parameter Description	<i>vrf vrf-name</i>	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	<i>ipv6-prefix</i>	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	<i>prefix-length</i>	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	nexthop-vrf <i>vrf-name1</i>	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by the VRF name. nexthop-vrf default indicates that the VRF of the next shop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	weight <i>number</i>	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-costroutes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
description <i>descri</i> <i>ption-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.	
Defaults	By default, no static route is configured.	

Command Mode	Global configuration mode
Usage Guide	The simplest configuration of this command is ipv6 route <i>ipv6-prefix / prefix-length</i> <i>ipv6-address</i> .

Verification

- Run the **show ip route** command to display the IPv4 routing table and check whether the configured IPv4 static route takes effect.
- Run the **show ipv6 route** command to display the IPv6 routing table and check whether the configured IPv6 static route takes effect.

Configuration Example

Configuring Static Routes to Implement Interworking of the IPv4 Network

<p>Scenario Figure 9-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure interface addresses on each device.
<p>R1</p>	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0</pre>
<p>R2</p>	<pre>R2#configure terminal</pre>

	<pre>R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/3 R2(config-if-GigabitEthernet 0/3)# ip address 1.1.23.2 255.255.255.0</pre>
R3	<pre>R3#configure terminal R3(config)#interface gigabitEthernet 0/0 R3(config-if-GigabitEthernet 0/0)# ip address 1.1.3.1 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/1 R3(config-if-GigabitEthernet 0/1)# ip address 1.1.13.3 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/2 R3(config-if-GigabitEthernet 0/2)# ip address 1.1.23.3 255.255.255.0</pre>

↘ **Correlating IPv4 Static Routes with Track**

<p>Scenario Figure 9-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure static routes on R 1 and R 2, and specify the exit interface or next hop as the interworking interface. ● Correlate static routes with Track on R 1 and R 2, and check the connectivity of the next hops of static routes. ●
R1	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit</pre>

	<pre>R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.2.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.2 track 2</pre>
R2	<pre>R2#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.1.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.1 track 2</pre>
Verification	<ul style="list-style-type: none"> ● Display the Track status. ● Display the static routes correlated with Track. <pre>R1# show track 2 Track 2 Interface gigabitEthernet 0/1 The state is Up, delayed Down (5 secs remaining) 1 change, current state last: 300 secs Delay up 0 secs, down 0 secs R1#show ip route track-table ip route 1.1.2.0 255.0.0.0 GigabitEthernet 0/1 1.1.12.2 track 2 up</pre>

➤ **Configuring Static Routes to Implement Interworking of the IPv6 Network**

<p>Scenario Figure 9-8</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure interface addresses on each device.
R1	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ipv6 address 1111:1111::1/64 R1(config-if-GigabitEthernet 0/0)# exit</pre>

	<pre>R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::1/64</pre>
R2	<pre>R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ipv6 address 1111:2323::1/64 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::2/64</pre>
	<ul style="list-style-type: none"> ● Configure static routes on each device.
R1	<pre>R1#configure terminal R1(config)# ipv6 route 1111:2323::0/64 gigabitEthernet 0/1</pre>
R2	<pre>R2#configure terminal R2(config)#ipv6 route 1111:1111::0/64 gigabitEthernet 0/1</pre>
Verification	<ul style="list-style-type: none"> ● Display the routing table.
R1	<pre>R1# show ipv6 route IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 1111:1111::/64 via GigabitEthernet 0/0, directly connected L 1111:1111::1/128 via GigabitEthernet 0/0, local host C 1111:1212::/64 via GigabitEthernet 0/1, directly connected L 1111:1212::1/128 via GigabitEthernet 0/1, local host S 1111:2323::/64 [1/0] via GigabitEthernet 0/1, directly connected C FE80::/10 via ::1, Null0</pre>

	<pre> C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host </pre>
R2	<pre> R2# show ipv6 route IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 1111:2323::/64 via GigabitEthernet 0/0, directly connected L 1111:2323::1/128 via GigabitEthernet 0/0, local host C 1111:1212::/64 via GigabitEthernet 0/1, directly connected L 1111:1212::1/128 via GigabitEthernet 0/1, local host S 1111:1111::/64 [1/0] via GigabitEthernet 0/1, directly connected C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host </pre>

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.
- The static route is correlated with Track, but the track object is not configured.

9.4.2 Configuring a Default Route

Configuration Effect

- Generate a default route in the routing table. The default route is used to forward packets that cannot be forwarded by other routes.

Notes

- On a L2 switch, run the **ip default gateway** or **ipv6 default gateway** command to configure the default gateway.
- On a L3 switch, run the **ip route 0.0.0.0 0.0.0.0 gateway** or **ipv6 route ::/0 ipv6-gateway** command to configure the default gateway.
- If the **no ip routing** or **no ipv6 unicast-routing** command is configured on a L3 switch, you can run the **ip default gateway** or **ipv6 default gateway** command to configure the default gateway.

Configuration Steps

↳ Configuring the IPv4 Gateway on a L2 Switch

Command	ip default-gateway <i>gateway</i>	
Parameter Description	<i>gateway</i>	indicates the IPv4 gateway address.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

↳ Configuring the IPv6 Gateway on a L2 Switch

Command	ipv6 default-gateway <i>gateway</i>	
Parameter Description	<i>gateway</i>	indicates the IPv6 gateway address.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	N/A	

↳ Configuring the IPv4 Default Gateway on a L3 Switch

Command	ip route [vrf <i>vrf_name</i>]0.0.0.0.0.0.0.0{<i>ip-address</i> <i>interface</i> [<i>ip-address</i>]} [<i>distance</i>] [tag <i>tag</i>] [permanent] [weight <i>number</i>] [description<i>description-text</i>] [disabled enabled]	
Parameter Description	vrf <i>vrf_name</i>	(Optional) Indicates the routing VRF, which can be a single-protocol IPv4 VRF or a multi-protocol VRF of a configured IPv4 address family. The VRF is a global VRF by default.
	0.0.0.0	Indicates the address of the destination network.
	0.0.0.0	Indicates the mask of the destination network.
	<i>ip-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>ip-address</i> is not specified, a static

		direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ip-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	<i>tag</i>	(Optional) Indicates the tag of the static route. The tag is 0 by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	weight number	(Optional) Indicates the weight of the static route. The weight is 1 by default.
	Description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
	disabled /enabled	(Optional) Indicates the enable flag of the static route. The flag is enabled by default.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ip route0.0.0.0 0.0.0.0 ip-address .	

↘ **Configuring the IPv6 Default Gateway on a L3 Switch**

Command	ipv6 route [vrf vrf-name] ::0 { ipv6-address [nexthop-vrf {vrf-name1 default}] interface [ipv6-address [nexthop-vrf {vrf-name1 default}]] } [distance] [weight number] [description description-text]	
Parameter Description	Vrf vrf-name	(Optional) Indicates the routing VRF, which must be a multi-protocol VRF of a configured IPv6 address family. The VRF is a global VRF by default.
	::	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC4291.
	0	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added in front of the length.
	<i>ipv6-address</i>	(Optional) Indicates the next-hop address of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>ipv6-address</i> is not specified, a static direct route is configured.
	<i>interface</i>	(Optional) Indicates the next-hop exit interface of the static route. You must specify at least one of <i>ipv6-address</i> and <i>interface</i> , or both of them. If <i>interface</i> is not specified, a recursive static direct route is configured. The exit interface is obtained by the next hop in the routing table.
	nexthop-vrf vrf-name1	(Optional) Indicates the routing VRF of the next hop, which must be a multi-protocol VRF of a configured IPv6 address family. By default, the VRF of the next hop is the same as the VRF specified by <i>vrf name</i> . nexthop-vrf default indicates that the VRF of the next shop is a global VRF.
	<i>distance</i>	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.

	weight <i>number</i>	(Optional) Indicates the weight of the static route, which must be specified when you configure equal-cost routes. The weight ranges from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
	Description <i>description-text</i>	(Optional) Indicates the description of the static route. By default, no description is configured. <i>description-text</i> is a string of one to 60 characters.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is ipv6 route ::/0 ipv6-gateway .	

↘ **Configuring the IPv4 Default Network on a L3 Switch**

Command	ip default-network <i>network</i>	
Parameter Description	<i>network</i>	Indicates the address of the network. (The network must be a Class A, B, or C network.)
Defaults	By default, no default network is configured.	
Command Mode	Global configuration mode	
Usage Guide	If the network specified by the ip default-network command exists, a default route is generated and the next hop to this network is the default gateway. If the network specified by the ip default-network command does not exist, the default route is not generated.	

Verification

- On a L2 switch (or a L3 switch where routing is disabled), run the **show ip redirects** or **show ipv6 redirects** command to display the default gateway.
- On a L3 switch where routing is enabled, run the **show ip route** or **show ipv6 route** command to display the default route.

Configuration Example

↘ **Configuring IPv4 Default Routes on L3 Switches to Implement Network Interworking**

Scenario Figure 9-9	
Configuration	<ul style="list-style-type: none"> ● Configure IP addresses on L3 devices.

Steps	
R1	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit</pre>
R2	<pre>R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/1)# exit</pre>
R1	<ul style="list-style-type: none"> ● Configure an IPv6 default gateway on R 1. <pre>R1#configure terminal R1(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.2</pre>
R2	<pre>R2#configure terminal R2(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.1</pre>
Verification	<ul style="list-style-type: none"> ● Display the routing table.
R1	<pre>R1# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is 1.1.12.2</pre>

S*	0.0.0.0/0 [1/0] via 1.1.12.2, GigabitEthernet 0/1
C	1.1.1.0/24 is directly connected, GigabitEthernet 0/0
C	1.1.1.1/32 is local host.
C	1.1.12.0/24 is directly connected, GigabitEthernet 0/1
C	1.1.12.1/32 is local host.

9.4.3 Configuring Route Limitations

Configuration Effect

- Limit the number of equal-cost routes and number of static routes, or disable routing.

Notes

Route limitations cannot be configured on a L2 switch.

Configuration Steps

▾ Configuring the Maximum Number of Equal-Cost Routes

Command	maximum-paths <i>number</i>
Parameter Description	<i>number</i> Indicates the maximum number of equal-cost routes. The value ranges from 1 to 64.
Defaults	The default value varies with the device model.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of next hops in the equal-cost route. In load balancing mode, the number of routes on which traffic is balanced does not exceed the configured number of equal-cost routes.

▾ Configuring the Maximum Number of IPv4 Static Routes

Command	ip static route-limit <i>number</i>
Parameter Description	<i>number</i> Indicates the upper limit of routes. The value ranges from 1 to 10,000.
Defaults	By default, a maximum of 1,024 IP static routes can be configured.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of IPv4 static routes. If the maximum number of IPv4 static routes is reached, no more IPv4 static route can be configured.

▾ Configuring the Maximum Number of IPv6 Static Routes

Command	ipv6 static route-limit <i>number</i>
----------------	--

Parameter	<i>number</i>	Indicates the upper limit of routes. The value ranges from 1 to 10,000.
Description		
Defaults		By default, a maximum of 1,000 IPv6 static routes can be configured.
Command		Global configuration mode
Mode		
Usage Guide		Run this command to configure the maximum number of IPv6 static routes. If the maximum number of IPv6 static routes is reached, no more IPv6 static route can be configured.

↘ Disabling IPv4 Routing

Command	no ip routing
Parameter	N/A
Description	
Defaults	By default, IPv4 routing is enabled.
Command	Global configuration mode
Mode	
Usage Guide	Run this command to disable IPv4 routing. If the device functions only as a bridge or a voice over IP (VoIP) gateway, the device does not need to use the IPv4 routing function of the NXOS software. In this case, you can disable the IPv4 routing function of the NXOS software.

↘ Disabling IPv6 Routing

Command	no ipv6 unicast-routing
Parameter	N/A
Description	
Defaults	By default, IPv6 routing is enabled.
Command	Global configuration mode
Mode	
Usage Guide	Run this command to disable IPv6 routing. If the device functions only as a bridge or a VoIP gateway, the device does not need to use the IPv6 routing function of the NXOS software. In this case, you can disable the IPv6 routing function of the NXOS software.

↘ Prohibiting Static Routing Across VRFs

Command	no ip route static inter-vrf
Parameter	N/A
Description	
Defaults	By default, static IP or IPv6 routing across VRFs is allowed.
Command	Global configuration mode
Mode	
Usage Guide	Run this command to prohibit static IP routing across VRFs. After this command is configured, the static IP route across VRFs is not active and cannot be participate in packet forwarding.

Verification

Run the **show run** command to display the configuration file and verify that the preceding configuration commands exist.

Configuration Example

Configuring at Most Two Static Routing Limitations

<p>Scenario Figure 9-10</p>	
<p>Configuration Steps</p>	<p>On R 1, configure the IP addresses, static routes, and maximum number of static routes.</p>
	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)#ip route 1.1.3.0 255.255.255.0 1.1.13.3 R1(config)#ip route 1.1.4.0 255.255.255.0 1.1.12.2 R1(config)#ip route 1.1.5.0 255.255.255.0 1.1.12.2 R1(config)#ip static route-limit 2 % Exceeding maximum static routes limit. </pre>

Verification	<ul style="list-style-type: none"> ● Check the static routes that really take effect in the routing table. <pre> R1(config)# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. S 1.1.3.0/24 [1/0] via 1.1.13.3 S 1.1.4.0/24 [1/0] via 1.1.12.2 C 1.1.12.0/24 is directly connected, GigabitEthernet 0/2 C 1.1.12.1/32 is local host. C 1.1.13.0/24 is directly connected, GigabitEthernet 0/3 C 1.1.13.1/32 is local host. </pre>
---------------------	---

9.4.4 Correlating a Static Route with BFD

Configuration Effect

- A static route can quickly detect a route failure with the help of BFD.

Notes

- BFD correlation cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure the BFD session parameters by running the **bfd interval xmin_rx xmultiplier x** command.

Configuration Steps

↘ Correlating an IPv4 Static Route with BFD

Command	ip route static bfd [vrf vrf-name]interface-type interface-number gateway[sourceip-address]	
Parameter	vrf vrf-name	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is

Description		a global VRF by default.
	<i>interface-type</i>	Indicates the interface type.
	<i>interface-number</i>	Indicates the interface number.
	<i>gateway</i>	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	source <i>ip-address</i>	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the source IP address is not specified.
Defaults	By default, a static route is not correlated with BFD.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to correlate an IPv4 static route with BFD. If the down status of the BFD session is detected, the IPv4 static route is not active and does not participate in packet forwarding.	

↘ Correlating an IPv6 Static Route with BFD

Command	ipv6 route static bfd [vrf <i>vrf-name</i>] <i>interface-type interface-number gateway</i> [source <i>ipv6-address</i>]	
Parameter Description	vrf <i>vrf-name</i>	(Optional) Indicates the name of the VRF to which the static route belongs. The VRF is a global VRF by default.
	<i>interface-type</i>	Indicates the interface type.
	<i>interface-number</i>	Indicates the interface number.
	<i>gateway</i>	Indicates the IP address of the gateway, that is, the neighbor IP address of BFD. If the next hop of the static route is this neighbor, BFD is used to check the connectivity of the forwarding path.
	source <i>ip-address</i>	(Optional) Indicates the source IP address used for the BFD session. This parameter must be configured if the neighbor IP address involves multiple hops. By default, the neighbor IP address of the BFD session is a single hop, and the source IP address is not used.
Defaults	By default, a static route is not correlated with BFD.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to correlate an IPv6 static route with BFD. If the down status of the BFD session is detected, the IPv6 static route is not active and does not participate in packet forwarding.	

Verification

- Run the **show bfd neighbors** command to display information about BFD neighbors.
- Run the **show ip route static bfd** or **show ipv6 route static bfd** command to display information about correlation of static routes with BFD.

Configuration Example

↘ **Correlating an IPv4 Static Route with BFD**

<p>Scenario Figure 9-11</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a BFD session on the interconnect interface between R 1 and R 2. ● Configure static routes on R 1 and R 2, and specify the exit interface or next hop as the interworking interface. ● Correlate static routes with BFD on R 1 and R 2, and check the connectivity of the next hops of static routes.
<p>R1</p>	<pre>R1#configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# no switchport R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R1(config-if-GigabitEthernet 0/1)# exit R1(config)# ip route 1.1.2.0 255.0.0.0 FastEthernet 0/1 1.1.12.2 R1(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.2</pre>
<p>R2</p>	<pre>R2#configure terminal R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# no switchport R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/1)#bfd interval 50 min_rx 50 multiplier 3 R2(config-if-GigabitEthernet 0/1)# exit R2(config)# ip route 1.1.1.0 255.0.0.0 FastEthernet 0/1 1.1.12.1 R2(config)#ip route static bfd gigabitEthernet 0/1 1.1.12.1</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Display the status of BFD neighbors. ● Display the static routes correlated with BFD.
<p>R1</p>	<pre>R1#show bfd neighbors OurAddr NeighAddr LD/RD RH/RS Holdown(mult) State Int</pre>

```

1.1.12.1 1.1.12.2 8192/0 Up 0(3 ) Up GigabitEthernet 0/1

R1#show ip route static bfd
S 1.1.2.0/24 via 1.1.12.2, GigabitEthernet 0/1, BFD state is Up
    
```

Common Errors

- The link on the interface is not up.
- No IP address is configured for the interface.
- No BFD session parameters are configured.
- No static route is configured.

9.4.5 Configure Static Fast Reroute

Configuration Effect

- Configure and enable static fast reroute.

Notes

- Static fast reroute cannot be configured on a L2 switch.
- You must configure a static route.
- You must configure a route map.

Configuration Steps

Defining a Standby Route in the Route Map

Command	set fast-reroute backup-nexthop <i>interface ip-address</i>	
Parameter	<i>interface</i>	Indicates the standby exit interface.
Description	<i>ip-address</i>	Indicates the standby next hop.
Defaults	N/A	
Command Mode	Global configuration mode	
Usage Guide	<p>Run the route-map <i>name</i> [permit deny] <i>sequence</i> command to create a road map.</p> <p>Run the match command to define matching conditions.</p> <p>Run the set fast-reroute backup-nexthop <i>interface ip-address</i> command to define the standby exit interface and standby next hop.</p> <p>If a route meets matching conditions, a standby route is generated for this route. If the match command is not configured, standby routes are generated for any static route with the exit interface and next hop.</p>	

Enabling Fast Reroute and Referencing the Route Map

Command	ip fast-reroute [vrf <i>vrf-name</i>] static route-map <i>route-map-name</i>	
Parameter Description	<i>vrf-name</i>	(Optional) Specifies a VRF. If the VRF is not specified, the command is executed on all VRFs.
	<i>route-map-name</i>	Indicates the name of the road map for the standby route.
Defaults	By default, static fast reroute is not configured.	
Command Mode	Global configuration mode	
Usage Guide	Run this command to enable fast reroute and reference the route map.	

Verification

Run the **show ip route fast-reroute** command to display the active and standby routes that take effect.

Configuration Example

Configuring Fast Re-Routing

<p>Scenario Figure 9-12</p>	
<p>Configuration Steps</p>	<p>On R 1, configure a static route to the network segment of PC 3, and the next hop of the exit interface is R 3. On R 1, configure static fast reroute. The next hop of the exit interface of the standby route is R2.</p>
	<pre> R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit </pre>

	<pre> R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3 R1(config)#route-map fast-reroute R1(config-route-map)# set fast-reroute backup-interface GigabitEthernet 0/2 backup-nexthop 1.1.12.2 R1(config-route-map)# exit R1(config)#ip fast-reroute static route-map fast-reroute </pre>
Verification	<p>Display the active and standby routes on R 1.</p> <pre> R1#show ip route fast-reroute Codes: C - connected, S - static, R - RIP, B - BGP O - OSPF, IA - OSPF inter area N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 ia - IS-IS inter area, * - candidate default Status codes: m - main entry, b - backup entry, a - active entry Gateway of last resort is no set S 1.1.3.0 /24 [ma] via 1.1.13.3, GigabitEthernet 0/3 [b] via 1.1.12.2, GigabitEthernet 0/2 </pre>

Common Errors

- The link on the interface is not up.
- No static route is configured.
- The matching conditions are not configured or are not properly configured in the road map.

9.5 Monitoring

Displaying

Description	Command
Displays the IPv4 routing table.	show ip route
Displays the IPv6 routing table.	show ipv6route

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs IPv4 route management.	debug nsm kernel ucast- v4
Debugs IPv6 route management.	debug nsm kernel ucast-v6
Debugs fast reroute management.	debug nsm kernel frr
Debugs default network management.	debug nsm kernel default-network

Debugs receiving of route management and routing protocol messages.	debug nsm packet recv

10 Configuring Keys

10.1 Overview

Keys are a kind of parameters that are used in algorithms for conversion from plain text to cipher text or from cipher text to plain text.

Plain text and cipher text authentication are supported for packet authentication in a routing protocol, during which keys need to be used.

i At present, keys are used only for RIP and ISIS packet authentication.

10.2 Applications

Application	Description
RIP Authentication	RIP uses keys for packet authentication.

10.2.1 RIP Authentication

Scenario

Network devices run RIP and use the MD5 authentication mode to increase the protocol security.

Figure 10-1

Deployment

- Configure a key chain on A. Configure RIP to enable packet authentication and use the key chain.
- Configure a key chain on B. Configure RIP to enable packet authentication and use the key chain.

10.3 Features

Overview

Feature	Description
Key Chain	Provide a tool for authentication in a routing protocol.

10.3.1 Key Chain

Working Principle

A key chain may contain multiple different keys. Each key contains the following attributes:

- **Key ID:** Identifies a key. In the current key chain, keys and IDs are mapped in the one-to-one manner.
- **Authentication string:** Indicates a set of key characters used for verifying the consistency of authentication strings in a routing protocol.
- **Lifetime:** Specifies the lifetime of the current key for sending or receiving packets. Different authentication keys can be used in different periods.

Related Configuration

↘ [Creating a Key Chain and a Key](#)

In the global configuration mode, run the **key chain** *key-chain-name* command to define a key chain and enter the key chain configuration mode.

In the key chain configuration mode, run the **key** *key-id* command to define a key and enter the key chain key configuration mode.

↘ [Configuring an Authentication String](#)

In the key chain key configuration mode, run the **key-string** **[0|7]** *text* command to specify an authentication string.

- A plain text authentication string is configured by default. The value **0** indicates that a plain text authentication key is configured.
- The value **7** indicates that a cipher text authentication string is configured.
- The encryption authentication service is disabled by default. You can run the **service password-encryption** command to enable the encryption service to forcibly convert plain text authentication into cipher text.

↘ [Configuring Lifetime](#)

In the key chain key configuration mode, you can configure the lifetime of a key chain in the receiving and sending directions.

- **accept-lifetime** *start-time* { **infinite** | *end-time* | **duration** *seconds* }: Configures the lifetime of a key chain in the receiving direction.
- **send-lifetime** *start-time* { **infinite** | *end-time* | **duration** *seconds* }: Configures the lifetime of a key chain in the sending direction.

10.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring a Key Chain	 (Mandatory) It is used to create a key.	
	key chain	Creates a key chain.
	key	Configures a key ID.
	key-string	Configures a key string.
	accept-lifetime	Configures the lifetime in the receiving direction.
	send-lifetime	Configures the lifetime in the sending direction.

10.4.1 Configuring a Key Chain

Configuration Effect

- Define a key chain to be used by a routing protocol.

Notes

- A key chain can take effect only after it is associated with a routing protocol.

Configuration Steps

▾ **Creating a Key Chain**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configuring a Key ID**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configuring a Key String**

- This configuration is mandatory if a key chain needs to be used.
- If there is no special requirement, you should perform this configuration on all routers for which routing protocol authentication needs to be performed.

▾ **Configure the Lifetime in the Receiving Direction**

- Optional.
- If the lifetime in the sending direction is not configured, the key chain will be always effective.

▾ **Configure the Lifetime in the Sending Direction**

- Optional.

- If the lifetime in the sending direction is not configured, the key chain will be always effective.

Verification

- Use keys in a routing protocol and observe the neighborhood established by the routing protocol. If the keys are inconsistent, the neighborhood fails to be established.

Related Commands

▾ Configuring a Key Chain

Command	key chain <i>key-chain-name</i>
Parameter Description	<i>key-chain-name</i> : Indicates the name of a key chain.
Command Mode	Global configuration mode
Usage Guide	To make a key chain take effect, you must configure at least one key.

▾ Configuring a Key ID

Command	key <i>key-id</i>
Parameter Description	<i>key-id</i> : Indicates the authentication key ID in a key chain, ranging from 0 to 2,147,483,647.
Command Mode	Key chain configuration mode.
Usage Guide	-

▾ Configuring a Key Authentication String

Command	key-string [0 7] <i>text</i>
Parameter Description	0 : Specifies that the key is displayed in plain text. 7 : Specifies that the key is displayed in cipher text. <i>text</i> : Specifies the authentication string characters.
Command Mode	Key chain key configuration mode.
Usage Guide	-

▾ Configuring the Lifetime in the Sending Direction

Command	send-lifetime <i>start-time</i> { infinite <i>end-time</i> duration <i>seconds</i> }
Parameter Description	start-time : Indicates the start time of the lifetime. infinite : Indicates that the key is always effective. end-time : Indicates the end time of the lifetime, which must be later than start-time. duration seconds : Specifies the duration from the start time to the end time, ranging from 1 to 2,147,483,646.
Command	Key chain key configuration mode.

Mode	
Usage Guide	Run this command to define the lifetime of the key in the sending direction.

↘ **Configuring the Lifetime in the Receiving Direction**

Command	accept-lifetime <i>start-time</i> {infinite <i>end-time</i> duration <i>seconds</i> }
Parameter Description	<p>start-time: Indicates the start time of the lifetime.</p> <p>infinite: Indicates that the key is always effective.</p> <p>end-time: Indicates the end time of the lifetime, which must be later than start-time.</p> <p>duration seconds: Specifies the duration from the start time to the end time, ranging from 1 to 2,147,483,646.</p>
Command Mode	Key chain key configuration mode.
Usage Guide	Run this command to define the lifetime of the key in the receiving direction.

Configuration Example

↘ **Configuring a Key Chain and Using the Key Chain in RIP Packet Authentication**

Scenario Figure 10-2	<p>The diagram shows two routers, A and B, connected via their G0/1 interfaces. Router A has the IP address 192.168.27.1/24. Router B has the IP address 192.168.27.2/24. Router B is also connected to a Static network with the IP address 172.168.1.0/24.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure a key on all routers. ● Configure RIP on all routers. ● Enable RIP authentication on all routers.
A	<pre>A>enable A#configure terminal A(config)#key chain ripchain A(config-keychain)#key 1 A(config-keychain-key)#key-string Hello A(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#exit A(config-keychain)#key 2</pre>

	<pre>A(config-keychain-key)#key-string World A(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#exit A(config)#interface gigabitEthernet 0/1 A(config-if)#ip address 192.168.27.1 255.255.255.0 A(config-if)#ip rip authentication key-chain ripchain A(config-if)#ip rip authentication mode md5 A(config-if)#exit A(config)#router rip A(config-router)#version 2 A(config-router)#network 192.168.27.0</pre>
B	<pre>B>enable B#configure terminal B(config)#key chain ripchain B(config-keychain)#key 1 B(config-keychain-key)#key-string Hello B(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#exit B(config-keychain)#key 2 B(config-keychain-key)#key-string World B(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#exit B(config)#interface gigabitEthernet 0/1 B(config-if)#ip address 192.168.27.2 255.255.255.0 B(config-if)#ip rip authentication key-chain ripchain B(config-if)#ip rip authentication mode md5 B(config-if)#exit B(config)#router rip</pre>

	<pre>B(config-router)#version 2 B(config-router)#network 192.168.27.0 B(config-router)#redistribute static</pre>
Verification	Run the show ip route rip command to check whether router A can receive an RIP route from router B.
A	<pre>A(config)#show ip route rip R 172.168.0.0/16 [120/1] via 192.168.27.2, 00:05:16, GigabitEthernet 0/1</pre>

Common Errors

- A key is not correctly associated with a routing protocol, which causes that authentication does not take effect.
- The keys configured on multiple routers are not consistent, which causes authentication failure.

10.5 Monitoring

Displaying

Description	Command
Displays the configurations of a key chain.	show key chain [<i>key-chain-name</i>]

11 Configuring Routing Policies

11.1 Overview

Routing policies are a policy set for changing the packet forwarding path or routing information and are often implemented by a filtering list and a route map. Routing policies are flexibly and widely applied in the following methods:

- Use a filtering list in a routing protocol to filter or modify routing information.
- Use a route map in a routing protocol to filter or modify routing information. Where, the route map can further use a filtering list.
- Use a route map in policy-based routing (PBR) to control packet forwarding or modify packet fields.

11.2 Applications

Application	Description
Route Filtering	Use a filtering list in a routing protocol to filter the routing information sent or received by the protocol.
Route Re-distribution	Use a route map in a routing protocol to filter or modify routing information and re-distribute RIP routes to OSPF. Only RIP routes with 4 hops can be re-distributed.
PBR	Use a route map in PBR to control packet forwarding or modify packet fields and specify optimum output interfaces for packets from different subnets.

11.2.1 Route Filtering

By default, a routing protocol advertises and learns all routing information. When a filtering list is used, the routing protocol advertises only required routes or receives only required routing information.

Scenario

Figure 11-1

As shown in Figure 11-1, router A has routes to 3 networks: 10.0.0.0, 20.0.0.0 and 30.0.0.0.

Configure a filtering list on the routers to achieve the following purposes:

- Filter the sent routing information on router A to filter routes that router A does not need to send.

- Filter the received routing information on router B to filter routes that router B does not need to learn.

Deployment

- Filter the sent routing information 30.0.0.0 on router A.
- Filter the received routing information 20.0.0.0 on router B to ensure that router B learns only routing information 10.0.0.0.

11.2.2 Route Re-distribution

By default, route re-distribution will re-distribute all routing information in a routing protocol to another routing protocol. All routing attributes will also be inherited. You can use a route map to perform conditional control for re-distribution between two routing protocols, including:

- Specify the range for re-distributing routes and re-distribute only routing information that meets certain rules.
- Set the attributes of routes generated by re-distribution.

Scenario

Figure 11-2

As shown in Figure 11-2, configure route re-distribution on the devices to achieve the following purposes:

- Re-distribute only RIP routes with 4 hops to OSPF.
- In the OSPF routing domain, the initial metric of this route is 40, the route type is the external route type-1 and the route tag value is set to 40.

Deployment

- Configure a route with 4 hops in the route map `rip_to_ospf`: match, and set the initial metric of this route to 40, the route type to the external route type-1 and the route tag value to 40.
- Configure route re-distribution to re-distribute RIP routes to OSPF and use the route map `rip_to_ospf`.

11.2.3 PBR

PBR is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured, where recursive routing supports automatic update with network changes. As compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on the source and destination addresses, packet length and input interface.

Scenario

Figure 11-3

Configure PBR on the layer-3 device DEV1 to achieve the following purposes:

- Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first.
- Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first.

Deployment

- Configure two different ACLs to match packets from subnets 1 and 2 respectively.
- Configure the route map RM_FOR_PBR: policy 10 is used to ensure that "packets from subnet 1 are sent from GE0/1 first"; policy 20 is used to ensure that "packets from subnet 2 are sent from GE0/2 first".
- Perform PBR for packets received from GE0/3 and use the route map RM_FOR_PBR.

11.3 Features

Overview

Feature	Description
Filtering List	Define a group of lists based on a route attribute, which can be used by a routing protocol for route filtering.
Route Map	A policy defines "if certain conditions are matched, you can perform certain processing actions".

11.3.1 Filtering List

Filtering lists are a group of lists defined based on a routing attribute and are a tool for filtering routing policies. Independent filtering lists are meaningless and can be used to filter routes only when they are applied in a routing protocol.

Working Principle

Based on different routing attributes, filtering lists are classified into the following types:

↘ Access Control List (ACL)

ACLs comprise IPv4 and IPv6 ACLs. When defining ACLs, you can specify IPv4/IPv6 addresses and masks to match the destination network segment or next-hop addresses of routing information.

For description about ACLs, see the *ACL Configuration Guide*.

↘ Address Prefix List (prefix-list)

Similar to ACLs, prefix-lists, including IPv4 prefix-lists and IPv6 prefix-lists, are used to match destination network segments of routing information during route filtering.

↘ AS-Path List

AS-path lists are used only for BGP. They are used to match AS paths during BGP route filtering.

↘ Community Attribute Filtering List (Community-List)

Community-lists are used only for BGP. They are used to match community attributes during BGP route filtering.

↘ Extended Community Attribute Filtering List (Extcommunity-List)

Extcommunity-lists are used only for BGP. They are used to match extended community attributes during BGP route filtering.

Related Configuration

↘ Creating an ACL

By default, no ACL is configured and no policy is set.

In the global configuration mode, run the **ip access-list { extended | standard } { id | name }** command to create an IPv4 ACL.

You can set multiple policies in an ACL, sorted by their sequence numbers. Policies have two working modes: permit and deny.

↘ Creating a Prefix-List

By default, no prefix-list is configured and no entry is set.

In the global configuration mode, run the **ip prefix-list prefix-list-name [seq seq-number] { deny | permit } ip-prefix [ge minimum-prefix-length] [le maximum-prefix-length]** command to create an IPv4 prefix-list and add a prefix entry to the list.

You can set multiple entries in the prefix-list, sorted by their sequence numbers. Entries have two working modes: permit and deny.

Run the **ip prefix-list prefix-list-name description description-text** command to add description to the prefix-list.

Run the **ip prefix-list sequence-number** command to enable the sorting function for the prefix-list.

↘ Creating an AS-Path List

By default, no AS-path list is configured and no entry is set.

In the global configuration mode, run the **ip as-path access-list** *path-list-num* { **permit** | **deny** } *regular-expression* command to create an AS-path list and add an entry to the list.

You can set multiple entries in the AS-path list. Entries have two working modes: permit and deny.

↳ Creating a Community-List

By default, no community-list is configured and no entry is set.

In the global configuration mode, run the **ip community-list** { { **standard** | **expanded** } *community-list-name* | *community-list-number* } { **permit** | **deny** } [*community-number..*] command to create a community-list and add an entry to the list.

You can set multiple entries in the community-list. Entries have two working modes: permit and deny.

↳ Creating an Extcommunity-List

By default, no extcommunity-list is configured and no entry is set.

In the global configuration mode, run the **ip extcommunity-list** { *standard-list* | **standard** *list-name* } { **permit** | **deny** } [*rt value*] [*soo value*] command to create a standard extcommunity list and add an entry to the list.

Run the **ip extcommunity-list** { *expanded-list* | **expanded** *list-name* } { **permit** | **deny** } [*regular-expression*] command to create an extcommunity list and add an entry to the list.

You can also run the **ip extcommunity-list** { *expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name* } command to create an extcommunity list and enter the configuration mode of **ip extcommunity-list** to add entries.

You can set multiple entries in the extcommunity-list. Entries have two working modes: permit and deny.

11.3.2 Route Map

A policy is a "match ..., set..." statement, which indicates that "if certain conditions are matched, you can perform some processing actions".

Working Principle

↳ Executing policies

A route map may contain multiple policies. Each policy has a corresponding sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be performed and the route map exits. If no matching condition of any policy is met, no processing action will be performed.

↳ Working Modes Of Policies

Policies have two working modes:

- **permit**: When the matching condition of a policy is met, the processing action for this policy will be performed and the route map will exit.
- **deny**: When the matching condition of a policy is met, the processing action for this policy will not be performed and the route map will exit.

↘ Matching Conditions Of Policies

The matching condition of a policy may contain 0, 1 or more match rules.

- If the matching condition contains 0 match rule, no packet will be matched.
- If the matching condition contains one or more match rules, all rules must be matched.

↘ Processing Action for a Policy

The processing action of a policy may contain 0, 1 or more set rules.

- If the processing action contains 0 set rule, no processing action will be performed and the route map will directly exit.
- If the processing action contains one or more set rules, all processing actions will be performed and then the route map will exit.

 If set rules have different priorities, the set rule with the highest priority will take effect.

Related Configuration

↘ Creating a Route Map (Policy)

By default, no route map is configured and no policy is set.

In the global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a route map and add a policy to the route map.

You can set multiple policies in a route map. Each policy uses different sequence numbers.

↘ Setting Matching Conditions of a Policy

By default, no match rule is set (that is, the matching condition of a policy contains 0 match rule).

In the route map mode, run the **match** command to set match rules. One **match** command is mapped to one match rule.

NXOS provides abundant **match** commands for setting flexible matching conditions.

Command	Description
match as-path	Uses the AS_PATH attribute of a BGP route as the matching condition.
match community	Uses the community attribute of a BGP route as the matching condition.
match extcommunity	Uses the extended community attribute of a BGP route as the matching condition.
match interface	Uses the output interface of a route as the matching condition.
match ip address	Uses the destination IPv4 address of a route as the matching condition.
match ip next-hop	Uses the next-hop IPv4 address of a route as the matching condition.
match ip route-source	Uses the source IPv4 address of a route as the matching condition.
match ipv6 address	Uses the destination IPv6 address of a route as the matching condition.
match ipv6 next-hop	Uses the next-hop IPv6 address of a route as the matching condition.
match ipv6 route-source	Uses the source IPv6 address of a route as the matching condition.
match metric	Uses the metric of a route as the matching condition.
match mpls-label	Uses whether a route has label information as the matching condition.

Command	Description
match origin	Uses the source of a route as the matching condition.
match route-type	Uses the type of a route as the matching condition.
match tag	Uses the tag value of a route as the matching condition.

📌 Setting the Processing Actions of a Policy

By default, no set rule is configured (that is, the processing action of a policy contains 0 set rule).

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

NXOS provides abundant **set** commands for setting flexible processing actions.

Command	Description
set aggregator as	Modifies the AS attribute value of a route aggregator.
set as-path prepend	Adds a specified as-path attribute value.
set as-path replace	Replace the specified as-path attribute value.
set atomic-aggregate	Sets the atomic-aggregate attribute of a route.
set comm-list delete	Deletes all community attribute values from the community attribute list for a route matching the match rules.
set community	Sets the community attribute value of a route.
set dampening	Sets the flapping parameters of a route.
set extcomm-list delete	Deletes all extended community attribute values from the extcommunity attribute list for a route matching the match rules.
set extcommunity	Sets the extended community attribute value of a route.
set fast-reroute	Sets the backup output interface and next hop of a fast reroute.
set ip default nexthop	Specifies the default next hop of a route. This command has a lower priority than a common route and a higher priority than set default interface .
set ip dscp	Modifies the dscp field of an IP packet.
set ip nexthop	Specifies the next hop of a route. This command has a higher priority than set interface .
set ip next-hop recursive	Specifies the recursive next-hop IP address of a route.
set ip next-hop verify-availability	Specifies the next-hop IP address of a route and checks the accessibility of the next hop by using a third-party protocol.
set ip precedence	Modifies the precedence field of an IP packet.
set ip tos	Modifies the tos field of an IP packet.
set ipv6 default next-hop	Specifies the default next hop of a route. This command has a lower priority than a common route and a higher priority than the default route.
set ipv6 next-hop	Specifies the IPv6 next hop of a route. This command has a higher priority than a common route.
set ipv6 next-hop verify-availability	Specifies the next-hop IP address of a route and checks the accessibility of the next hop by using a third-party protocol.
set ipv6 precedence	Sets the priority of an IPv6 packet header.

Command	Description
set level	Sets the destination area type to which a route will be directed.
set local-preference	Sets the local-preference attribute value of a route.
set metric	Modifies the metric value of a route.
set metric-type	Sets the metric type of a route.
set mpls-label	Sets the MPLS label.
set next-hop	Sets the next-hop IP address of a route.
set origin	Sets the source attribute of a route.
set originator-id	Sets the originator IP address of a route.
set tag	Sets the tag value of a route.
set weight	Sets the weight value of a route.

11.4 Configuration

Configuration	Description and Command	
Configuring a Route Map	 (Optional) It is used to define a policy.	
	route-map	Creates a policy (route map).
	match	Sets the matching conditions of the policy.
	set	Sets the processing actions of the policy.
Configuring a Filtering List	 (Optional) It is used to define a filtering list.	
	ip as-path	Defines AS path filtering rules.
	ip community-list	Defines a community list.
	ip extcommunity-list	Defines an extcommunity list.
	ip prefix-list	Creates a prefix-list.
	ip prefix-list description	Adds description to a prefix-list.
	ip prefix-list sequence-number	Enables the sorting function for a prefix-list.
	ipv6 prefix-list	Creates an IPv6 prefix-list.
ipv6 prefix-list description	Adds description to an IPv6 prefix-list.	
ipv6 prefix-list sequence-number	Enables the sorting function for an IPv6 prefix-list.	

11.4.1 Configuring a Route Map

Configuration Effect

- Define a set of routing policies to be used by routing protocols or PBR.

Notes

- If a **match** command uses an ACL to define packet matching conditions, the ACL must be configured.

- The following **match** commands cannot be configured at the same time:

The Following match Commands	Cannot Be Configured with the Following match Commands At the Same Time
match ip address	match ip prefix-list
match ipv6 address	match ipv6 prefix-list
match ip next-hop	match ip next-hop prefix-list
match ipv6 next-hop	match ipv6 next-hop prefix-list
match ip route-source	match ip route-source prefix-list
match ipv6 route-source	match ipv6 route-source prefix-list

- The following **set** commands cannot be configured at the same time:

The Following set Commands	Cannot Be Configured with the Following set Commands At the Same Time
set next-hop	set vrf
set ip next-hop	set ip next-hop verify-availability
set ip dscp	set ip tos
set ip dscp	set ip precedence

Configuration Steps

↳ Creating a Policy (Route Map)

- Mandatory.
- Perform this configuration on a device to which a policy needs to be applied.

↳ Setting Matching Conditions of a Policy

- Optional.
- If no match rule is configured, no packet will be matched.
- If multiple match rules are configured, all the match rules must be matched.
- Perform this configuration on a device to which a policy needs to be applied.

↳ Setting the Processing Actions of a Policy

- Optional.
- If no set rule is configured, no processing action will be performed.
- If multiple set rules are configured, all set rules must be executed (if the set rules have different priorities, the set rule with the highest priority takes effect).
- Perform this configuration on a device to which a policy needs to be applied.

Verification

- Check the configurations of the route map.

Related Commands

↳ Creating a Policy (Route Map)

Command	route-map <i>route-map-name</i> [{ permit deny } <i>sequence</i>]
Parameter Description	<i>route-map-name</i> : Indicates the name of a route map, comprising not more than 32 characters. permit : Specifies the working mode of this policy as permit, which is the default mode. deny : Specifies the working mode of this policy as deny. The default mode is permit. <i>sequence</i> : Specifies the sequence number of this policy. A smaller value means a higher priority. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	If this route map is unavailable, this command will create a route map and add a policy to the route map. If this route map is available, this command will add a policy to the route map.

↳ Setting Matching Conditions of a Policy

Command	match as-path <i>as-path-acl-list-number</i> [<i>as-path-acl-list-number</i>]
Parameter Description	<i>as-path-acl-list-number</i> : Indicates the AS-PATH list number, ranging from 1 to 500.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the AS-PATH attribute of a BGP route. Run the ip as-path access-list <i>path-list-num</i> { permit deny } <i>regular-expression</i> command to configure the AS-PATH list.

Command	match community { <i>community-list-number</i> <i>community-list-name</i> } [exact-match] [{ <i>community-list-number</i> <i>community-list-name</i> } [exact-match] ...]
Parameter Description	<i>community-list-number</i> : Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extcommunity list, the value ranges from 100 to 199. <i>community-list-name</i> : Indicates the community list name, comprising not more than 80 characters. exact-match : Indicates the exact match list. It is a non-exact match list by default, that is, the match rule is met as long as the routing attributes contain the attributes specified by a community list.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the community attribute specified in a community list.

Command	match extcommunity { <i>standard-list-number</i> <i>standard-list-name</i> <i>expanded-list-num</i> <i>expanded-list-name</i> }
Parameter Description	<i>standard-list-number</i> : Indicates an ID, ranging from 1 to 99. It is used to identify a standard extcommunity list. One extcommunity list may contain multiple extcommunity values. <i>standard-list-name</i> : Indicates the name of a standard extcommunity list. It is used to identify the name of a standard extcommunity list. One extcommunity list may contain multiple extcommunity values.

	<p><i>expanded-list-num</i>: Indicates an ID, ranging from 100 to 199. It is used to identify an extcommunity list. One extcommunity list may contain multiple extcommunity values.</p> <p><i>expanded-list-name</i>: Indicates the name of an extcommunity. It is used to identify the name of an extcommunity list. One extcommunity list may contain multiple extcommunity values.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the extended community attribute specified in an extcommunity list.

Command	match interface <i>interface-type interface-number</i> [<i>...interface-type interface-number</i>]
Parameter Description	<i>interface-type interface-number</i> : Indicates the interface type and interface number.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the next-hop output interface of a route or a packet.

Command	match ip address { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
Parameter Description	<p><i>access-list-number</i>: Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699.</p> <p><i>access-list-name</i>: Indicates the access list name.</p> <p>prefix-list <i>prefix-list-name</i>: Indicates the name of a prefix-list to be matched.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv4 address of a packet or route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ip next-hop { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
Parameter Description	<p><i>access-list-number</i>: Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699.</p> <p><i>access-list-name</i>: Indicates the access list name.</p> <p>prefix-list <i>prefix-list-name</i>: Indicates the name of a prefix-list to be matched.</p>
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ip route-source { <i>access-list-number</i> [<i>access-list-number...</i> <i>access-list-name...</i>] <i>access-list-name</i> [<i>access-list-number...</i> <i>access-list-name</i>] prefix-list <i>prefix-list-name</i> [<i>prefix-list-name...</i>] }
----------------	---

Parameter Description	<i>access-list-number</i> : Indicates the access list number. For a standard access list, the value ranges are 1 to 99 and 1300 to 1999. For an extended access list, the value ranges are 100 to 199 and 2000 to 2699. <i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of a prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ipv6 address { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv6 address of a packet or route by using an ACL or a prefix-list. An ACL and a prefix list cannot be configured at the same time.

Command	match ipv6 next-hop { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match ipv6 route-source { <i>access-list-name</i> prefix-list <i>prefix-list-name</i> }
Parameter Description	<i>access-list-name</i> : Indicates the access list name. prefix-list <i>prefix-list-name</i> : Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured at the same time.

Command	match metric <i>metric</i>
Parameter Description	<i>metric</i> : Indicates the metric value of a route, ranging from 0 to 4,294,967,295.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the metric value of a route.

Command	match mpls-label
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match routing information with labels.

Command	match origin { egp igp incomplete }
Parameter Description	egp: Indicates the source is remote EGP. igp: Indicates the source is local IGP. incomplete: Indicates that the source is an incomplete type.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the source of a route.

Command	match route-type { local internal external [type-1 type-2] level-1 level-2}}
Parameter Description	local: Indicates a route locally generated. Internal: Indicates an internal OSPF route. external: Indicates an external route (that of BGP or OSPF). type-1 type-2: Indicates type-1 or type-2 external route of OSPF. level-1 level-2: Indicates level-1 or level-2 route of ISIS.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the type of a route.

Command	match tag tag [...tag]
Parameter Description	tag: Indicates the tag value of a route.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the tag value of a route.

📌 Setting the Processing Actions of a Policy

Command	set aggregator as as-number ip-address
Parameter Description	as-number: Indicates the AS number of an aggregator. The AS number ranges from 1 to 4,294,967,295, which can be indicated by 1 to 65535.65535 in the dot mode. ip-address: Indicates the address of an aggregator.
Command Mode	Route map configuration mode

Usage Guide	This set rule is used to modify the AS attribute value of a route's aggregator.
--------------------	---

Command	set as-path prepend <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates the AS number to be added to the AS_PATH attribute. The AS number ranges from 1 to 4,294,967,295, which can be indicated by 1 to 65535.65535 in the dot mode.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to add a specified as-path attribute value.

Command	set as-path replace <i>as-number</i>
Parameter Description	<i>as-number</i> : Indicates the AS number which will replace the AS_PATH attribute. The AS number ranges from 1 to 4,294,967,295, which can be indicated by 1 to 65535.65535 in the dot mode.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to replace the specified as-path attribute value.

Command	set atomic-aggregate
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the atomic-aggregate attribute of a route.

Command	set comm-list { <i>community-list-number</i> <i>community-list-name</i> } delete
Parameter Description	<i>community-list-number</i> : Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extcommunity list, the value ranges from 100 to 199. <i>community-list-name</i> : Indicates the community list name, comprising not more than 80 characters.
Command Mode	Route map configuration mode
Usage Guide	This rule is used to delete all community attribute values from the community list for a route matching the match rules.

Command	set community { <i>community-number</i> [<i>community-number</i> ...] additive none }
Parameter Description	<i>community-number</i> : Indicates the community attribute value. additive : Adds a number based on the original community attribute. none : Keeps the community attribute empty.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the community attribute value of a route.

Command	set dampening <i>half-life reuse suppress max-suppress-time</i>
Parameter Description	<p><i>half-life</i>: half-life when a route is accessible or not accessible, ranging from 1 to 45 minutes. The default value is 15 minutes.</p> <p><i>reuse</i>: When the penalty value of a route is smaller than this value, route suppression will be canceled. The value ranges from 1 to 20,000 and the default value is 750.</p> <p><i>suppress</i>: When the penalty value of a route is greater than this value, the route will be suppressed. The value ranges from 1 to 20,000 and the default value is 2,000.</p> <p><i>max-suppress-time</i>: Indicates the longest time that a route can be suppressed, ranging from 1 to 255 minutes. The default value is 4 x half-life.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the flapping parameters of a route.

Command	set extcomm-list { <i>extcommunity-list-number</i> <i>extcommunity-list-name</i> } delete
Parameter Description	<p><i>extcommunity-list-number</i>: Indicates the extcommunity list number. For a standard extcommunity list, the value ranges from 1 to 99. For an extended extcommunity list, the value ranges from 100 to 199.</p> <p><i>extcommunity-list-name</i>: Indicates the extcommunity list name, comprising not more than 80 characters.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to delete all extended community attribute values from the extcommunity attribute list for a route matching the match rules.

Command	set extcommunity { <i>rt extend-community-value</i> soo <i>extend-community-value</i> }
Parameter Description	<p>rt: Sets the RT attribute value of a route.</p> <p>soo: Sets the SOO attribute value of a route.</p> <p><i>extend-community-value</i>: Indicates the value of an extended community.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the extended community attribute value of a route.

Command	set fast-reroute backup-interface <i>interface-type interface-number</i> [backup-nexthop <i>ip-address</i>]
Parameter Description	<p><i>interface-type interface-number</i>: Specifies a backup output interface.</p> <p>backup-nexthop <i>ip-address</i>: Specifies a backup next hop. For a non-point-to-point interface, a backup next hop must be specified.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the backup output interface and next hop of a fast reroute.

Command	set ip default next-hop <i>ip-address</i> [<i>weight</i>] [... <i>ip-address</i> [<i>weight</i>]]
----------------	--

Parameter	<i>ip-address</i> : Indicates the next-hop IP address.
Description	<i>weight</i> : Indicates the weight of this next hop.
Command	Route map configuration mode
Mode	
Usage Guide	This set rule is used to specify the default next hop of a route.

Command	set ip dscp <i>dscp_value</i>
Parameter	<i>dscp_value</i> : Sets the DSCP value in the IP header of an IP packet.
Description	
Command	Route map configuration mode
Mode	
Usage Guide	This set rule is used to modify the dscp field of an IP packet.

Command	set ip next-hop <i>ip-address</i> [<i>weight</i>] [... <i>ip-address</i> [<i>weight</i>]]
Parameter	<i>ip-address</i> : Indicates the next-hop IP address.
Description	<i>weight</i> : Indicates the weight of this next hop.
Command	Route map configuration mode
Mode	
Usage Guide	This set rule is used to specify the next hop of a route.

Command	set ip next-hop recursive <i>ip-address</i>
Parameter	<i>ip-address</i> : Indicates the recursive next-hop IP address.
Description	
Command	Route map configuration mode
Mode	
Usage Guide	This command is used only for PBR configuration. This set rule is used to specify the recursive next hop of a route. An IP address can recur to a static or dynamic route that has an output interface and a next-hop IP address. A maximum of 32 next hops are supported. If a recursive route is a static route, only one next hop is supported for the static recursive route.

Command	set ip next-hop verify-availability <i>ip-address</i> [bfd <i>interface-type interface-number gateway</i>]
Parameter	<i>ip-address</i> : Indicates the next-hop IP address.
Description	bfd : Indicates that BFD is used for neighbor detection. <i>interface-type</i> : Configures the interface type. <i>interface-number</i> : Configures the interface number. <i>gateway</i> : Configures the gateway IP address, which is the neighbor IP address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path.
Command	Route map configuration mode
Mode	
Usage Guide	This set rule is used to specify the next hop of a route and BFD or Track is used to fast detect the

	effectiveness of the next hop.
--	--------------------------------

Command	set ip precedence { <i>number</i> critical flash flash-override immediate internet network priority routine }
Parameter Description	<i>number</i> : Indicates the priority of the IP header with a number, ranging from 0 to 7. 7: critical 6: flash 5: flash-override 4: immediate 3: internet 2: network 1: priority 0: routine critical flash flash-override immediate internet network priority routine : priority of an IP header.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the precedence field of an IP packet header.

Command	set ip tos { <i>number</i> max-reliability max-throughput min-delay min-monetary-cost normal }
Parameter Description	<i>number</i> : Indicates the TOS value of an IP header with a number, ranging from 0 to 15. 2: max-reliability 4: max-throughput 8: min-delay 1: min-monetary-cost 0: normal max-reliability max-throughput min-delay min-monetary-cost normal : priority of an IP header.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the tos field of an IP packet.

Command	set ipv6 default next-hop <i>global-ipv6-address</i> [<i>weight</i>] [<i>global-ipv6-address</i> [<i>weight</i>] ...]
Parameter Description	<i>global-ipv6-address</i> : Indicates the next-hop IPv6 address for packet forwarding. The next-hop router must be a neighbor router. <i>weight</i> : Indicates the weight in the load balancing mode, ranging from 1 to 8. A larger value means larger packet traffic to be shared by the next hop.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the default next hop IPv6 address of a route.

Command	set ipv6 next-hop <i>global-ipv6-address</i> [<i>weight</i>] [<i>global-ipv6-address</i> [<i>weight</i>] ...]
----------------	--

Parameter Description	<p><i>global-ipv6-address</i>: Indicates the next-hop IPv6 address for packet forwarding. The next-hop router must be a neighbor router.</p> <p><i>weight</i>: Indicates the weight in the load balancing mode, ranging from 1 to 8. A larger value means larger packet traffic to be shared by the next hop.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop IPv6 address of a route.

Command	set ipv6 next-hop verify-availability <i>global-ipv6-address</i> bfd <i>interface-type</i> <i>interface-number</i> <i>gateway</i>
Parameter Description	<p>global-ipv6-address: Indicates the next-hop IPv6 address.</p> <p>bfd: Indicates that BFD is used for neighbor detection.</p> <p><i>interface-type</i>: Configures the interface type.</p> <p><i>interface-number</i>: Configures the interface number.</p> <p><i>gateway</i>: Configures the gateway IPv6 address, which is the neighbor IPv6 address of BFD. If the next hop is configured as the neighbor, BFD will be used to detect the accessibility of the forwarding path.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to specify the next hop of a route and BFD is used to fast detect the effectiveness of the next hop.

Command	set ipv6 precedence { <i>number</i> critical flash flash-override immediate internet network priority routine }
Parameter Description	<p><i>number</i>: Indicates the priority of the IP header with a number, ranging from 0 to 7.</p> <p>7: critical</p> <p>6: flash</p> <p>5: flash-override</p> <p>4: immediate</p> <p>3: internet</p> <p>2: network</p> <p>1: priority</p> <p>0: routine</p> <p>critical flash flash-override immediate internet network priority routine: priority of an IP header.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the priority of an IPv6 packet header.

Command	set level { level-1 level-2 level-1-2 stub-area backbone }
Parameter Description	<p>level-1: Indicates that the re-distribution route is advertised to ISIS Level 1.</p> <p>level-2: Indicates that the re-distribution route is advertised to ISIS Level 2.</p>

	<p>level-1-2: Indicates that the re-distribution route is advertised to ISIS Level 1 and Level 2.</p> <p>stub-area: Indicates that the re-distribution route is advertised to OSPF Stub Area.</p> <p>backbone: Indicates that the re-distribution route is advertised to the OSPF backbone area.</p>
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the destination area type to which a route will be redirected.

Command	set local-preference <i>number</i>
Parameter Description	<i>number:</i> Indicates the metric value of a local priority, ranging from 0 to 4,294,967,295. A larger value means a higher priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the local-preference attribute value of a route.

Command	set metric [+ <i>metric-value</i> - <i>metric-value</i> <i>metric-value</i>]
Parameter Description	+: Increases (based on the metric value of the original route). -: Decreases (based on the metric value of the original route). <i>metric-value:</i> Sets the metric value of a re-distribution route. A larger value means a lower priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the metric value of a route.

Command	set metric-type <i>type</i>
Parameter Description	<i>type:</i> Sets the type of a re-distribution route. The default type of an OSPF re-distribution route is type-2.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the metric type.

Command	set mpls-label
Parameter Description	-
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the MPLS label.

Command	set next-hop <i>ip-address</i>
Parameter Description	<i>ip-address:</i> Indicates the next-hop IP address.
Command	Route map configuration mode

Mode	
Usage Guide	This set rule is used to set the next-hop IP address.

Command	set origin { egp igp incomplete }
Parameter Description	egp: Indicates the source is remote EGP. igp: Indicates the source is local IGP. incomplete: Indicates that the source is the incomplete type and generally refers to a route generated due to re-distribution.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the source attribute of a route.

Command	set originator-id <i>ip-address</i>
Parameter Description	<i>ip-address:</i> Indicates the address of an originator.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the originator IP address of a route.

Command	set tag <i>tag</i>
Parameter Description	<i>tag:</i> Sets the tag of a re-distribution route.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the tag value of a route.

Command	set weight <i>number</i>
Parameter Description	<i>number:</i> Sets the weight of a route, ranging from 0 to 65,535. A larger value means a higher priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the weight of a route.

↘ Displaying the Configurations of a Route Map

Command	show route-map [<i>name</i>]
Parameter Description	<i>name:</i> Specifies a route map.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	Run the show route-map command to display the configurations of a route map.

	If an ACL is used when a route map is configured, you can run the show access-list command to display the configurations of the ACL.
--	---

Configuration Example

Using a Route Map in Route Re-distribution to Filter and Modify Routing Information

Scenario Figure 11-4	<p>As shown in Figure 11-4, a device is connected to both an OSPF routing domain and RIP routing domain.</p> 
	<ul style="list-style-type: none"> Re-distribute only RIP routes with 4 hops to OSPF. In the OSPF route domain, if the route type is the external route type-1, set the tag value of the route to 40. Re-distribute only OSPF routes with the tag value 10 to RIP. In the RIP route domain, set the initial metric value of this route to 10.
Configuration Steps	<ul style="list-style-type: none"> Configure the route map redrip: Match a route with 4 hops, set the initial metric value of the route to 40, set the route type to the external route type-1, and set the tag value of the route to 40. Configure the route map redospf: match a route with the tag value 10 and set the initial metric value of the route to 10. Configure re-distribution of the RIP route to OSPF and apply the route map redrip. Configure re-distribution of the OSPF route to RIP and apply the route map redospf.
	<pre>Nodexon(config)# route-map redrip permit 10 Nodexon(config-route-map)# match metric 4 Nodexon(config-route-map)# set metric-type type-1 Nodexon(config-route-map)# set tag 40 Nodexon(config-route-map)# exit Nodexon(config)# route-map redospf permit 10 Nodexon(config-route-map)# match tag 10 Nodexon(config-route-map)# set metric 10 Nodexon(config-route-map)# exit Nodexon(config)# router ospf 1 Nodexon(config-router)# redistribute rip subnets route-map redrip Nodexon(config-router)# exit Nodexon(config)# router rip Nodexon(config-router)# redistribute ospf 1 route-map redospf Nodexon(config-router)# exit</pre>
Verification	<ul style="list-style-type: none"> Check the configurations of the route map to verify the policy rules.

	<ul style="list-style-type: none"> ● Check the OSPF routing information library to verify that the rules matching the policy rules are re-distributed.
	<pre>Nodexon# show route-map route-map redrip, permit, sequence 10 Match clauses: metric 4 Set clauses: metric 40 metric-type type-1 tag 40 route-map redospf, permit, sequence 10 Match clauses: tag 10 Set clauses: metric 10</pre>
	<pre>Nodexon# show ip ospf database external OSPF Router with ID (192.100.1.9) (Process ID 1) AS External Link States LS age: 5 Options: 0x2 (- - - - - E -) LS Type: AS-external-LSA Link State ID: 192.168.199.0 (External Network Number) Advertising Router: 192.100.1.9 LS Seq Number: 80000001 Checksum: 0x554d Length: 36 Network Mask: /24 Metric Type: 1 TOS: 0</pre>

<p>Metric: 4</p> <p>Forward Address: 0.0.0.0</p> <p>External Route Tag: 40</p>
--

📌 Applying a Route Map in PBR

<p>Scenario</p> <p>Figure 11-5</p>	
	<p>Configure PBR on the device DEV1 to achieve the following purposes:</p> <ul style="list-style-type: none"> ● Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first. ● Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first. ● The two output links work in the mutual backup mode.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure two different ACLs to match packets from subnets 1 and 2 respectively. ● Configure the route map RM_FOR_PBR: policy 10 is used to ensure that "packets from subnet 1 are sent from GE0/1 first"; policy 20 is used to ensure that "packets from subnet 2 are sent from GE0/2 first". ● Configure PBR for packets received from GE0/3 and apply the route map RM_FOR_PBR. ● Set PBR to implement redundant backup among multiple next hops. <p>⚠ In the redundant backup mode, the sequence of multiple set next hops is the sequence of the priorities for taking effect.</p>

	<pre>Nodexon(config)# access-list 1 permit 200.24.16.0 0.0.0.255 Nodexon(config)# access-list 2 permit 200.24.17.0 0.0.0.255 Nodexon(config)# route-map RM_FOR_PBR 10 Nodexon(config-route-map)# match ip address 1 Nodexon(config-route-map)# set ip next-hop 200.24.19.1 Nodexon(config-route-map)# exit Nodexon(config)# route-map RM_FOR_PBR 20 Nodexon(config-route-map)# match ip address 2 Nodexon(config-route-map)# set ip next-hop 200.24.18.1 Nodexon(config-route-map)# exit Nodexon(config)# interface GigabitEthernet 0/3 Nodexon(config-if)# ip policy route-map RM_FOR_PBR</pre>
<p>Verification</p>	<pre>Nodexon(config)# ip policy redundancy</pre> <ul style="list-style-type: none"> ● Check the configurations of PBR to verify that the route map is applied to the interfaces. ● Check the configurations of the route map to verify the policy rules. ● Check the ACL configurations to verify the packet filtering rules.
	<pre>Nodexon# show ip policy Balance mode: redundancy Interface Route map ----- - GigabitEthernet 0/3 RM_FOR_PBR !</pre>
	<pre>Nodexon# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop 200.24.18.1 ip next-hop 200.24.19.1 route-map RM_FOR_PBR, permit, sequence 20</pre>

	<pre>Match clauses: ip address 2 Set clauses: ip next-hop 200.24.19.1 ip next-hop 200.24.18.1</pre>

Common Errors

- After matching of ACLs and prefix-lists is configured, the corresponding ACLs and prefix lists are not defined.

11.4.2 Configuring a Filtering List

Configuration Effect

- Define a set of route filtering rules to be used by routing protocols.

Notes

- A configured filtering list can take effect only after it is associated with a routing protocol.

Configuration Steps

▾ Configuring a Prefix-List

- To filter address prefixes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which filtering based on a prefix-list needs to be performed.

▾ Configuring an AS Path List

- To filter address prefixes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which filtering based on an AS path needs to be performed.

▾ Configuring a Community List

- To filter community attributes, you should perform this configuration.

- If there is no special requirement, you should perform this configuration on a route for which community attributes need to be filtered.

↘ Configuring an Extcommunity List

- To filter extended community attributes, you should perform this configuration.
- If there is no special requirement, you should perform this configuration on a route for which extended community attributes need to be filtered.

Verification

- Check whether the filtering list is correctly configured.
- Check the routing table to verify that routes can be correctly filtered.

Related Commands

↘ Defining AS Path Filtering Rules

Command	<code>ip as-path access-list path-list-num { permit deny } regular-expression</code>
Parameter Description	<p><i>path-list-num</i>: Indicates an AS-path ACL name based on a regular expression and is an AS path list identifier, ranging from 1 to 500.</p> <p>permit: Permits access.</p> <p>deny: Denies access.</p> <p><i>regular-expression</i>: Indicates a regular expression, ranging from 1 to 255.</p>
Command Mode	Global configuration mode
Usage Guide	-

↘ Defining a Community List

Command	<code>ip community-list { { standard expanded } community-list-name community-list-number } { permit deny } [community-number..]</code>
Parameter Description	<p>standard: Indicates a standard community list.</p> <p>expanded: Indicates an extended community list.</p> <p><i>community-list-name</i>: Indicates the community list name, comprising not more than 80 characters.</p> <p><i>community-list-number</i>: Indicates the community list number. For a standard community list, the value ranges from 1 to 99. For an extended community list, the value ranges from 100 to 199.</p> <p>permit: Permits access.</p> <p>deny: Denies access.</p> <p><i>community-number</i>: Indicates the community attribute value.</p>
Command Mode	Global configuration mode
Usage Guide	Use this command to define a community list used for BGP.

↘ Defining an Extcommunity List

Command	ip extcommunity-list { <i>expanded-list</i> expanded <i>list-name</i> } { permit deny } [<i>regular-expression</i>]
Parameter Description	<p><i>expand-list</i>: Indicates an extended extcommunity list, ranging from 100 to 199. One extcommunity list may contain multiple rules.</p> <p><i>standard-list</i>: Indicates a standard extcommunity list, ranging from 1 to 99. One extcommunity list may contain multiple rules.</p> <p><i>expanded list-name</i>: Indicates the name of an extended extcommunity, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.</p> <p><i>standard list-name</i>: Indicates the name of a standard extcommunity list, comprising not more than 32 characters. When using this parameter, you enter the extcommunity list configuration mode.</p> <p>permit: Defines an extcommunity rule for permitting.</p> <p>deny: Defines an extcommunity rule for denying.</p> <p><i>regular-expression</i>: (optional) Defines a matching template that is used to match an extcommunity.</p> <p><i>sequence-number</i>: (Optional) Defines the sequence number of a rule, ranging from 1 to 2,147,483,647. If no sequence number is specified, the sequence number automatically increases by 10 when a rule is added by default. The initial number is 10.</p> <p>rt: (Optional) Sets the RT attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.</p> <p>soo: (Optional) Sets the SOO attribute value. This command can be used only for the standard extcommunity configuration, but not for the extended extcommunity configuration.</p> <p><i>value</i>: Indicates the value of an extended community (<i>extend_community_value</i>).</p>
Command Mode	Global configuration mode and ip extcommunity-list configuration mode
Usage Guide	-

📄 Creating a Prefix-List

Command	ip prefix-list <i>prefix-list-name</i> [seq <i>seq-number</i>] { deny permit } <i>ip-prefix</i> [ge <i>minimum-prefix-length</i>] [le <i>maximum-prefix-length</i>]
Parameter Description	<p><i>prefix-list-name</i>: Indicates the prefix-list name.</p> <p><i>seq-number</i>: Assigns a sequence number to an prefix-list entry, ranging from 1 to 2,147,483,647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number.</p> <p>deny: Denies access when certain conditions are matched.</p> <p>permit: Permits access when certain conditions are matched.</p> <p><i>ip-prefix</i>: Configures the IP address and mask, ranging from 0 to 32 digits.</p> <p><i>minimum-prefix-length</i>: Specifies the minimum range (namely, the start length of a range).</p> <p><i>maximum-prefix-length</i>: Specifies the maximum range (namely, the end length of a range).</p>
Command Mode	Global configuration mode
Usage Guide	-

▾ Adding Description to a Prefix-List

Command	ip prefix-list <i>prefix-list-name</i> description <i>descripton-text</i>
Parameter	<i>prefix-list-name</i> : Indicates the prefix-list name.
Description	<i>descripton-text</i> : Describes the prefix-list.
Command Mode	Global configuration mode
Usage Guide	-

▾ Enabling the Sorting Function for a Prefix-List

Command	ip prefix-list sequence-number
Parameter	-
Description	
Command Mode	Global configuration mode
Usage Guide	-

▾ Creating an IPv6 Prefix-List

Command	ipv6 prefix-list <i>prefix-list-name</i> [seq <i>seq-number</i>] { deny permit } <i>ipv6-prefix</i> [ge <i>minimum-prefix-length</i>] [le <i>maximum-prefix-length</i>]
Parameter	<i>prefix-list-name</i> : Indicates the prefix-list name.
Description	<p><i>seq-number</i>: Assigns a sequence number to an prefix-list entry, ranging from 1 to 2,147,483,647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number.</p> <p>deny: Denies access when certain conditions are matched.</p> <p>permit: Permits access when certain conditions are matched.</p> <p><i>ipv6-prefix</i>: Configures the IP address and mask, ranging from 0 to 128 digits.</p> <p><i>minimum-prefix-length</i>: Specifies the minimum range (namely, the start length of a range).</p> <p><i>maximum-prefix-length</i>: Specifies the maximum range (namely, the end length of a range).</p>
Command Mode	Global configuration mode
Usage Guide	-

▾ Adding Description to an IPv6 Prefix List

Command	ipv6 prefix-list <i>prefix-list-name</i> description <i>descripton-text</i>
Parameter	<i>prefix-list-name</i> : Indicates the prefix list name.
Description	<i>descripton-text</i> : Describes the prefix list.
Command Mode	Global configuration mode

Usage Guide	-
--------------------	---

▾ **Enabling the Sorting Function for an IPv6 Prefix-List**

Command	ipv6 prefix-list sequence-number
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

▾ **Configuring a Prefix-List**

<p>Scenario Figure 11-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an IBGP neighbor and advertise the neighbor to the three connected subnets. ● Configure a prefix-list. ● Associate a prefix-list with A to filter sent routes.
<p>A</p>	<pre>A# configure terminal A(config)# ip prefix-list pre1 permit 192.168.1.0/24 A(config)# router bgp 100 A(config-router)# neighbor 1.1.1.2 prefix-list pre1 out A(config-router)# end</pre>

<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show command to display the prefix-list. ● Run the show command to display the BGP routing table to check whether the filtering behavior is correct.
<p>A</p>	<pre>A# show ip prefix-list ip prefix-list prel: 1 entries seq 5 permit 192.168.1.0/24 A# show ip bgp BGP table version is 2, local router ID is 1.1.1.1 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 192.168.1.0 0.0.0.0 0 32768 i *> 192.168.2.0 0.0.0.0 0 32768 i *> 192.168.3.0 0.0.0.0 0 32768 i Total number of prefixes 3</pre>
<p>B</p>	<pre>B# show ip bgp BGP table version is 4, local router ID is 1.1.1.2 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *>i192.168.1.0 1.1.1.1 0 100 0 i Total number of prefixes 1</pre>

➤ **Configuring an AS Path List**

<p>Scenario Figure 11-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Create an AS-path filtering rule to match path information including only AS 200. ● Establish EBGP neighborhood on A with B and C. ● Associate an AS-path list with A to filter the routes received from B and C.
<p>A</p>	<pre>A(config)# ip as-path access-list 123 permit ^200\$ A(config)# router bgp 100 A(config)# neighbor 192.168.1.2 filter-list 123 in A(config)# neighbor 192.168.2.2 filter-list 123 in</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show command to display the AS-path list. ● Run the show command to display the BGP routing table to check whether the filtering behavior is correct.
<p>A</p>	<pre>A# show ip as-path-access-list AS path access list 123 permit ^200\$ //When no AS-path list is associated with A, run the show command to check the BGP routing table. A(config)# show ip bgp BGP table version is 1, local router ID is 1.1.1.1 Status codes: s suppressed, d damped, h history, * valid, > best, i - internal, S Stale, b - backup entry Origin codes: i - IGP, e - EGP, ? - incomplete Network Next Hop Metric LocPrf Weight Path *> 10.0.0.0/24 192.168.1.2 0 0 200 i</pre>

1 Configuring IP Multicast

1.1 Overview

IP multicast is abstracted hardware multicasting and an extended multicast routing protocol on the standard IP network layer. In traditional IP transmission, only one host can send packets to a single host (unicast communication) or all hosts (broadcast communication). However, the multicast technology provides the third choice: a host can send packets to certain specified hosts.

IP multicast is applicable to one-to-many multimedia applications.

1.2 Applications

Application	Description
PIM-DM Applications	The PIM-DM multicast service is provided on the same network.
PIM-SM Applications	The PIM-SM multicast service is provided on the same network.

1.2.1 PIM-DM Applications

Scenario

The PIM-DM multicast service is provided on the same network.

As shown in Figure 1-1:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-1

Remarks	<p>A and B are layer-3 devices and C is a layer-2 access device.</p> <p>Source is connected to the Gi 0/1 interface of A, and receiver A and receiver B are connected to the Gi 0/2 and Gi 0/3 interfaces of C.</p>
----------------	---

Deployment

- Run the Open Shortest Path First (OSPF) protocol on the same network to implement unicast routing.
- Run PIM-DM on the same network to implement multicast routing.
- Run the Internet Group Membership Protocol (IGMP) in a user host network segment to implement group member management.

1.2.2 PIM-SM Applications

Scenario

The PIM-SM multicast service is provided on the same network.

As shown in Figure 1-2:

- A multicast source sends a multicast packet, and receiver A and receiver B on the same network receive the multicast packet.

Figure 1-2

Remarks	<p>A, B, and C are layer-3 routers.</p> <p>The multicast source is connected to the Gi 0/1 interface of A, receiver B is connected to the Gi 0/1 interface of B, and receiver B is connected to the Gi 0/1 interface of C.</p>
----------------	--

Deployment

- Run OSPF on the same network to implement unicast routing.
- Run PIM-SM on the same network to implement multicast routing.
- Run IGMP in a user host network segment to implement group member management.

1.3 Features

Basic Concepts

↘ PIM Routers and PIM Interfaces

Routers enabled with PIM are called PIM routers. Interfaces enabled with PIM protocol are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for sending multicast packets are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments. The network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On certain PIM interfaces, borders are configured to divide a large PIM network into multiple PIM domains. Borders may reject specified multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR and RP

Multicast packets are transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called a multicast distribution tree (MDT) and has the following types:

- Rendezvous Point Tree (RPT): The RP is regarded as the root and the designated router (DR) that connects group members is regarded as a leaf.
- Shortest Path Tree (SPT): The DR that connects multicast sources is regarded as the root, and RP or DR that connects group members is regarded as a leaf.

The DR and RP are functional roles for a PIM router.

- The RP collects multicast sources and group member information on the network.
- The DR that connects multicast sources reports multicast source information to the RP. The DR that connects group members reports group member information to the RP.

↘ (*,G) and (S,G)

- (*,G): Packets sent from any source to group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Packets sent from source S to group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

↘ ASM and SSM

PIM-SM supports the following multicast models that are applicable to different multicast address segments:

- Any-Source Multicast (ASM): In the ASM model, user hosts cannot select multicast sources. User hosts join a group and receive packets sent from all sources to the group.
- Source-Specific Multicast (SSM): In the SSM model, user hosts can select multicast sources. User hosts specify source addresses when joining a group and receive only packets sent from specified sources to the group.

i SSM model requirements: User hosts must know the multicast source address in advance using other network services so that the hosts can select multicast sources.

Overview

Feature	Description
Configuring Basic Functions of IP Multicast	Creates a PIM network and provides data sources and user terminals on the network with the IPv4 multicast service.
Configuring a TTL Threshold	Configures a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	Allows the multicast forwarding path to be different from the unicast path.
Configuring Layer-2 Direction Control for Multicast Streams	Allows a specified multicast stream to be configured with multiple commands, that is, to be configured with multiple ports that can forward the stream. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.
Configuring RPF Route Selection Based on the Longest Match Rule	Selects an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among these three routes, the one with the longest match mask is selected as the RPF route.

Feature	Description
Configuring Multicast Non-Stop Forwarding Parameters	During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of the multicast protocol.
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	Deletes the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

1.3.1 Configuring Basic Functions of IP Multicast

Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Working Principle

A device maintains the routing table for forwarding multicast packets through multicast routing protocols (such as PIM-DM or PIM-SM) and learns the states of group members in the directly connected network segment through IGMP. A host sends IGMP Report messages to join a specified IGMP group.

Related Configuration

▾ [Enabling IPv4 Multicast Routing](#)

By default, IPv4 multicast routing is disabled.

Run **ip multicast-routing** to enable IPv4 multicast routing.

▾ [Configuring IP Multicast on an Interface](#)

By default, IP multicast is disabled on an interface.

Run **ip pim sparse-mode** or **ip pim dense-mode** to enable IP multicast on an interface.

1.3.2 Configuring a TTL Threshold

Configure a TTL threshold for an interface, that is, the minimum TTL value of multicast packets allowed on an interface.

Working Principle

Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Related Configuration

▾ Configuring a TTL Threshold

By default, the TTL threshold of an interface is 0.

Run **ip multicast ttl-threshold** *ttl-value* to change the TTL threshold of an interface. The value ranges from 0 to 255.

A larger value of *ttl-value* means a larger TTL value of multicast packets to be forwarded.

1.3.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Working Principle

The number of entries in the IP multicast routing table is limited based on the actual network and service performance requirements to ensure device performance.

Related Configuration

▾ Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

By default, a maximum of 1024 entries can be added to an IP multicast routing table.

Run **ip multicast route-limit** *limit* [*threshold*] to change the number of entries that can be added to the IP multicast routing table. The value ranges from 1 to 65536.

A larger value of *limit* means a larger number of entries that can be added to the IP multicast routing table.

1.3.4 Configuring an IP Multicasting Border

Configure an IP multicasting border to specify the transmission range of multicast packets.

Working Principle

An IP multicasting border is configured to specify the transmission range of multicast packets. When an IP multicasting border is configured on an interface, this interface cannot forward or receive multicast packets, including those sent from the local host.

Related Configuration

↘ Configuring an IP Multicasting Border

By default, no IP multicasting border is configured.

Run **ip multicast boundary** *access-list* [**in** | **out**] to configure an IP multicasting border.

1.3.5 Configuring an IP Multicasting Static Route

Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Working Principle

An RPF check is performed once multicast packets are forwarded. An IP multicasting static route can be configured to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Related Configuration

↘ Configuring an IP Multicasting Static Route

By default, no IP multicasting static route is configured.

Run **ip mroute** *source-address mask* { [**bgp** | **isis** | **ospf** | **rip** | **static**] { *v4rpf-address* | *interface-type interface-number* } } [*distance*] to configure an IP multicasting static route.

1.3.6 Configuring Layer-2 Direction Control for Multicast Streams

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Working Principle

Configure layer-2 direction control for multicast streams and a forwarding interface so that multicast streams can be forwarded only through configured interfaces. In this case, layer-2 forwarding of multicast streams can be controlled.

Related Configuration

↘ Configuring Layer-2 Direction Control for Multicast Streams

By default, layer-2 direction control for multicast streams is disabled.

Run **ip multicast static** *source-address group-address interface-type interface-number* to configure layer-2 direction control for multicast streams.

1.3.7 Configuring RPF Route Selection Based on the Longest Match Rule

Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Working Principle

A multicast static route, an MBGP route, and a unicast route that can be used for RPF check are selected respectively from the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules.

- If the longest match rule is used, the route with the longest match mask is selected as the RPF route. If the three routes have the same mask, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.
- Otherwise, the one with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

📄 Configuring RPF Route Selection Based on the Longest Match Rule

By default, the route with the highest priority is selected as the RPF route. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.

Run **ip multicast rpf longest-match** to configure RPF route selection based on the longest match rule.

1.3.8 Configuring Multicast Non-Stop Forwarding Parameters

The non-stop forwarding function ensures continuous forwarding of multicast data streams during the re-convergence of multicast protocols.

Working Principle

During normal running, SSP synchronizes the hardware multicast forwarding table to the management board in real time. After the management board is switched, the command for configuring the multicast control plane of the original slave management board is loaded, and the multicast protocol (such as PIM-SM or IGMP Snooping) re-converges. The multicast non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

After the configured protocol convergence period times out, all multicast forwarding table entries that are not updated during the convergence period are deleted.

Related Configuration

📄 Configuring the Maximum Period for Multicast Protocol Convergence

By default, the maximum period for multicast protocol convergence is 20s.

Run **msf nsf convergence-time *time*** to configure the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s.

A larger value of *time* means a longer maximum period for multicast protocol convergence.

📄 Configuring the Multicast Packet Leakage Period

By default, the multicast packet leakage period is 30s.

Run **msf nsf leak interval** to configure the multicast packet leakage period. The value ranges from 0 to 3600s.

A larger value of *interval* means a longer leakage period.

1.3.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Working Principle

Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries .

Related Configuration

▾ [Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries](#)

By default, the overwriting mechanism upon the overflow of multicast hardware forwarding entries is disabled.

Run **msf ipmc-overflow override** to configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of IP Multicast	 (Mandatory) It is used to configure the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.
Configuring a TTL Threshold	 Optional.	
	ip multicast ttl-threshold <i>ttl-value</i>	Configures a TTL threshold for an interface.
Configuring the Number of Entries That Can Be Added to the Multicast Routing Table	ip multicast route-limit <i>limit</i> [<i>threshold</i>]	Limits the number of entries that can be added to the multicast routing table.
Configuring an IP Multicasting Border	ip multicast boundary <i>access-list</i> [in out]	Configures an interface as a multicast border for a specified group.
Configuring an IP Multicasting Static Route	ip mroute <i>source-address mask</i> { [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } } [<i>distance</i>]	Configures an IP multicasting static route.

Configuring Layer-2 Direction Control for Multicast Streams	ip multicast static <i>source-address group-address interface-type interface-number</i>	Controls the direction of data streams on layer-2 interfaces.
Configuring RPF Route Selection Based on the Longest Match Rule	ip multicast rpf longest-match	Configures RPF route selection based on the longest match rule.
Configuring Multicast Non-Stop Forwarding Parameters	msf nsf convergence-time <i>time</i>	Configures the maximum period for multicast protocol convergence.
	msf nsf leak <i>time</i>	Configures the multicast packet leakage period.
Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries	msf ipmc-overflow override	Configures the overwriting mechanism upon overflow of multicast hardware forwarding entries.

1.4.1 Configuring Basic Functions of IP Multicast

Configuration Effect

- Create a PIM network and provide data sources and user terminals on the network with the IPv4 multicast service.

Notes

- A PIM network needs to use existing unicast routes on the network. Therefore, IPv4 routes must be configured on the network.

Configuration Steps

▾ Enabling IPv4 Multicast Routing

- Mandatory.
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

▾ Enabling IP Multicast for an Interface

- Mandatory.
- IP multicast protocol should be enabled on interfaces unless otherwise specified:

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Check whether the user hosts can successfully receive packets from each group.

Related Commands

▾ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring IP Multicast

-  For IGMP configuration, see the IGMP section.
-  For PIM-DM configuration, see the PIM-DM section.
-  For PIM-SM configuration, see the PIM-SM section.
-  After layer-3 multicasting is enabled in the private VLAN and super VLAN and a multicast source exists in the sub-VLAN, an extra entry whose ingress is the sub-VLAN into which the multicast stream enters needs to be copied due to the validity check during multicast forwarding. This results in occupation of one more multicast hardware entry and one less in the multicast capacity.

↘ Displaying Information About the Multicast Forwarding Table

Command	show ip mroute [group-or-source-address [group-or-source-address]] [dense sparse] [summary count]
Parameter Description	<p><i>group-or-source-address</i>: Specifies a group address or source address.</p> <p><i>group-or-source-address</i>: Specifies a group address or source address.</p> <p>dense: Displays the core entry of PIM-DM multicast.</p> <p>sparse: Displays the core entry of PIM-SM multicast.</p> <p>summary: Displays summary information about multicast routing entries.</p> <p>count: Displays counting information about multicast routing entries.</p>
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>The three parameters are optional, and the source address and group address must be specified simultaneously.</p> <p>When no source address or group address is specified, all MFC entries are displayed.</p> <p>When only the source address and group address are specified, MFC entries of the source address and group address are displayed.</p>

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

<p>Scenario Figure 1-3</p>	 <p>The diagram illustrates a network topology for IP multicast. On the left, a 'Multicast Source' (server icon) is connected to Router A via interface Gi0/1. Router A is connected to Router B via interface Gi0/2. Router B is connected to 'Receiver A' (laptop icon) via interface Gi0/1.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an IPv4 unicast routing protocol (such as OSPF) on a router. ● Enable IPv4 multicast routing on all routers. ● Enable PIM-DM on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>
<p>B</p>	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit</pre>
<p>Verification</p>	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p>

	<ul style="list-style-type: none"> ● Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from G. ● Check multicast forwarding tables on A and B.
A	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:01:55, stat expires 00:02:19 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1)</pre>
B	<pre>B# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:35, stat expires 00:02:55 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1)</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

- IPv4 multicast routing is not enabled on a router.
- IP multicast is not enabled on an interface.

1.4.2 Configuring a TTL Threshold

Configuration Effect

- Configure a TTL threshold for an interface and check the TTL values of multicast packets. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- Set a TTL threshold on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups.

- Set a TTL threshold to a value that is larger than the TTL value of the multicast packet on the PIM router interface directly connected to the user host and check whether the user can receive the multicast packet.

Related Commands

↘ Configuring a TTL Threshold

Command	<code>ip multicast ttl-threshold <i>ttl-value</i></code>
Parameter Description	<i>ttl-value</i> : Specifies a TTL threshold for an interface. The value ranges from 0 to 255. The default value is 0.
Command Mode	Interface configuration mode
Usage Guide	A multicast-enabled device can retain a TTL threshold for each interface. Multicast packets whose TTL values are larger than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded. A TTL threshold takes effect only for multicast frames and must be configured on layer-3 interfaces.

Configuration Example

↘ Creating the IP Multicast Service on the IPv4 Network and Configuring a TTL Threshold

<p>Scenario Figure 1-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● Configure the TTL threshold as 100 on the Gi 0/2 interface of device A.
<p>A</p>	<pre>A# configure terminal A(config)#int gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ip multicast ttl-threshold 100 A(config-if-GigabitEthernet 0/2)# exit</pre>
<p>Verification</p>	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p> <ul style="list-style-type: none"> ● Configure the TTL threshold as 100 on the Gi 0/2 interface of device A, which is larger than the TTL value of the multicast packet. ● Check the difference between the route forwarding entries before and after the TTL threshold is configured.
<p>Before Configuring the TTL Threshold</p>	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:08, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list:</pre>

	GigabitEthernet 0/2 (1)
After Configuring the TTL Threshold	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.3), uptime 00:00:01, stat expires 00:03:29 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (100)</pre>

1.4.3 Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Configuration Effect

- Each multicast data packet received on the device maintains a corresponding IP multicast route forwarding entry. However, excess multicast routing entries may exhaust device memory and deteriorate device performance. You can limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- Limit the number of entries in the IP multicast routing table based on the actual network and service performance requirements.

Verification

Send N groups of multicast packets from the multicast source on the network, configure user hosts to join the groups, configure the number of entries that can be added to the IP multicast routing table as N-1, and check whether the multicast packet received by the user host is that of the N-1 group.

Related Commands

Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Command	<code>ip multicast route-limit limit [threshold]</code>
Parameter Description	<p><i>limit</i>: Specifies the number of entries in the multicast routing table. The value ranges from 1 to 65536. The default value is 1024.</p> <p><i>threshold</i>: Specifies the number of entries in the multicast routing table that triggers the warning message. The default value is 65536.</p>
Command Mode	Global configuration mode
Usage Guide	Due to limitations on hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, deteriorating the performance.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring the Number of Entries That Can Be Added to the Multicast Routing Table

Scenario Figure 1-5	
Configuration Steps	<ul style="list-style-type: none"> Configure basic the functions of IP multicast. (Omitted) Configure the number of entries that can be added to the multicast routing table on device B as 2.
B	<pre>B# configure terminal B(config)# ip multicast route-limit 2</pre>
Verification	<p>Enable the multicast source (192.168.1.100) to send packets to G1 (233.3.3.1), G2 (233.3.3.2), and G3 (233.3.3.3). Enable receiver A to join G1, G2, and G3.</p> <ul style="list-style-type: none"> Check multicast packets received by receiver A. Receiver A should be able to receive multicast packets from two groups among G1, G2, and G3. Check multicast routing entries on A and B. When the number of entries in the IP multicast routing table reaches the upper threshold, a prompt message is displayed.

A	<pre>A# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (TTL) (192.168.1.100, 233.3.3.1), uptime 00:00:06, stat expires 00:03:24 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.2), uptime 00:00:05, stat expires 00:03:25 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1) (192.168.1.100, 233.3.3.3), uptime 00:00:00, stat expires 00:03:30 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (1)</pre>
B	<pre>B# show ip mroute IP Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry</pre>

	<pre> Interface State: Interface (TTL) (192.168.1.100, 233.3.3.1), uptime 00:01:13, stat expires 00:03:23 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1) (192.168.1.100, 233.3.3.3), uptime 00:06:08, stat expires 00:03:23 Owner PIMDM, Flags: TFS Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (1) </pre>
	<p>When the number of entries in the IP multicast routing table reaches the upper threshold, a prompt message is displayed.</p> <pre> B##Dec 26 10:43:07: %MROUTE-4-ROU TELIMIT: IPv4 Multicast route limit 2 exceeded - VRF default. </pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.4 Configuring an IP Multicasting Border

Configuration Effect

- Configure an IP multicasting border to specify the transmission range of multicast packets.

Notes

- The basic functions of IP multicasting must be configured.

Configuration Steps

- Configure an IP multicasting border on PIM router interfaces unless otherwise specified.

Verification

Enable multicast sources to send multicast packets and user hosts to join the groups. Configure an IP multicasting border on the PIM router interface connected to the user host and check whether the user can receive the multicast packet.

Related Commands

▾ Enabling IPv4 Multicast Routing

Command	ip multicast boundary <i>access-list</i> [in out]
Parameter Description	<i>access-list</i> : Indicates the group address range defined by ACL. in : Indicates that the IP multicasting border takes effect in the incoming direction of the multicast stream. out : Indicates that the IP multicasting border takes effect in the outgoing direction of the multicast stream.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, IGMP and PIM-SM packets in the group range are filtered on this interface and multicast data streams are not going in and out through this interface. The ACL associated with this command can be a standard ACL or an extended ACL. For extended ACLs, only the destination address is matched and the source address is matched.

Configuration Example

▾ Creating the IP Multicast Service on the IPv4 Network and Configuring an IP Multicasting Border

Scenario Figure 1-6	<p>The diagram illustrates a network topology for IP multicast. A Multicast Source is connected to Router A via interface Gi0/1. Router A is connected to Router B via interface Gi0/2. Router B is connected to Receiver A via interface Gi0/1.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● Configure an ACL on device A. ● Configure an IP multicasting border on the Gi 0/1 interface of device A.
A	<pre>A# configure terminal A(config)#ip access-list standard ip_multicast A(config-std-nacl)#deny any A(config-std-nacl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit</pre>

Verification	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.3). Enable receiver A to join G.</p> <ul style="list-style-type: none"> ● Run debug ip pim sparse-mode events.
A	<pre>A# debug ip pim sparse-mode events Jan 1 20:58:34: %7: VRF(0): No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 *Jan 1 20:58:34: %7: VRF(0): Ignore No cache message: src 192.168.1.100 for 233.3.3.3 vif 2 in PIM_BOUNDARY_FLT_BOTH range</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.5 Configuring an IP Multicasting Static Route

Configuration Effect

- Configure an IP multicasting static route to specify an RPF interface or RPF neighbor for multicast packets from specified multicast sources.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- An IP multicasting static route can be configured on each device unless otherwise specified.

Verification

Run **show ip rpf source-address** to check the RPF information of a specified source.

Related Commands

📄 Configuring Basic Functions of IP Multicast

Command	ip mroute <i>source-address mask</i> { [bgp isis ospf rip static] { <i>v4rpf-address</i> <i>interface-type interface-number</i> } } [<i>distance</i>]
Parameter Description	<p><i>source-address</i>: Specifies the multicast source address.</p> <p><i>mask</i>: Specifies the mask of the multicast source address.</p> <p><i>protocol</i>: Indicates the unicast routing protocol currently used.</p> <p><i>rpf-address</i>: Specifies the address of the RPF neighbor (next hop of the multicast source).</p> <p><i>interface-type interface-number</i>: Indicates the RPF interface (outgoing interface of the multicast source).</p> <p><i>distance</i>: Specifies the route management distance. The value ranges from 0 to 255. The default value is 0.</p>
Command	Global configuration mode

Mode	
Usage	Multicast static routes are applicable only to RPF check.
Guide	If the IP address of the outgoing interface, but not the next hop, of the static multicast route needs to be specified, the outgoing interface must be a point-to-point type.

↘ **Displaying the RFP Information of a Specified Source Address**

Command	show ip rpf <i>source-address</i>
Parameter Description	<i>source-address</i> : Specifies the source IP address.
Command Mode	Privilege, global and interface configuration modes
Usage Guide	<p>The three parameters are optional, and the source address and group address must be specified simultaneously.</p> <p>When no source address or group address is specified, all MFC entries are displayed.</p> <p>When only the source address and group address are specified, MFC entries of the source address and group address are displayed.</p>

Configuration Example

↘ **Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM**

Scenario Figure 1-7	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● Configure a static route to the receiver on device B.
A	<pre>B# configure terminal B(config)# ip mroute 10.10.10.10 255.255.255.255 ospf 192.168.1.1 1</pre>
Verification	Run show ip rpf to view the RPF information to the receiver before and after the configuration.

Before Configuration	<pre>B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
After Configuration	<pre>B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0 RPF neighbor: 192.168.1.1 RPF route: 10.10.10.10/32 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 1 Metric: 0</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.

1.4.6 Configuring Layer-2 Direction Control for Multicast Streams

Configuration Effect

Configure layer-2 direction control for multicast streams to control the forwarding of multicast streams on an interface.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- Layer-2 direction control for multicast streams can be configured on layer-2 devices unless otherwise specified.

Verification

Send multicast packets on the network containing layer-2 device A, connect multiple user hosts to VLAN 1 of layer-2 device A to receive the group, configure layer-2 direction control for multicast streams on device A, and check whether multicast packets are sent to the configured layer-2 interface.

Related Commands

Configuring Layer-2 Direction Control for Multicast Streams

Command	ip multicast static <i>source-address group-address interface-type interface-number</i>
Parameter Description	<i>source -address</i> : Specifies the multicast source address. <i>group-address</i> : Specifies the multicast group address. <i>interface-type interface-number</i> : Specifies a layer-2 interface that is allowed to forward the multicast flow.
Command Mode	Global configuration mode
Usage Guide	Allow a specified multicast flow to be configured with multiple commands, that is, to be configured with multiple interfaces. Once direction control is configured for a multicast stream, the stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream. This command controls only the forwarding of multicast streams on the interface, but does not directly affect the processing of multicast protocols on the protocol packets. However, since certain features of the multicast protocol are driven by multicast data streams, behaviors of the multicast routing protocols may also be affected.

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring Layer-2 Direction Control for Multicast Streams

Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● Configure layer-2 direction control for multicast streams on device B so that the streams are sent only to the Gi 0/2 interface.
B	<pre>A# configure terminal A(config)# ip multicast static 192.168.1.100 233.3.3.3 gigabitEthernet0/2</pre>
Verification	<p>Enable the multicast source (192.168.1.100) to send packets to G (233.3.3.1). Enable receivers A and B to join G.</p> <ul style="list-style-type: none"> ● Check multicast packets received by receiver A. Receiver B should not be able to receive multicast packets from G.

Common Errors

- An IPv4 unicast route is incorrectly configured.

1.4.7 Configuring RPF Route Selection Based on the Longest Match Rule

Configuration Effect

- Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table and select the one with the longest match mask as the RPF route from the three optimal routes.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- Configure RPF route selection based on the longest match rule on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route to have the same priority and configure the unicast static route to have a longer mask length.

- Run **show ip rpf source-address** to check the RPF information of a specified source.

Related Commands

📌 Configuring RPF Route Selection Based on the Longest Match Rule

Command	ip multicast rpf longest-match
Parameter Description	-
Command	Global configuration mode

Mode	
Usage Guide	<p>The steps for selecting RFP routes are as follows:</p> <ol style="list-style-type: none"> 1, Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table for RPF check. 2, Select one from the three routes as the RPF route. <p>If the longest match rule is used, the route with the longest match mask is selected. If the three routes have the same mask, the one with the highest priority is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.</p> <p>If the longest match rule is not used, the route with the longest match mask is selected. If they have the same priority, the RPF routes are selected in the sequence of multicast static route, MBGP route, and unicast route.</p>

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring RPF Route Selection Based on the Longest Match Rule

Scenario Figure 1-9	
Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● On device B, configure an IP multicast static route whose mask length is smaller than that of the unicast static route. ● Configure RPF route selection based on the longest match rule on device B.
B	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# ip mroute 10.10.10.10 255.255.0.0 ospf 192.168.1.1 B(config)# ip multicast rpf longest-match</pre>
Verification	Run show ip rpf to check the RFP information of the multicast source before and after configuring RPF route selection based on the longest match rule.
Before configuration	<pre>B#show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/0</pre>

	<pre>RPF neighbor: 192.168.1.1 RPF route: 10.10.0.0/16 RPF type: static RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 0 Metric: 0</pre>
After configuration	<pre>B# show ip rpf 10.10.10.10 RPF information for 10.10.10.10 RPF interface: GigabitEthernet 0/2 RPF neighbor: 192.168.2.1 RPF route: 10.10.10.10/32 RPF type: unicast (ospf) RPF recursion count: 0 Doing prefix-length-preferred lookups across tables Distance: 110 Metric: 1</pre>

Common Errors

- An IPv4 unicast route is incorrectly configured.
- IPv4 multicast routing is not enabled on a router.

1.4.8 Configuring Multicast Non-Stop Forwarding Parameters

Configuration Effect

- The non-stop forwarding function ensures continuous forwarding of multicast data streams during re-convergence of multicast protocols.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

▾ Configuring the Maximum Period for Multicast Protocol Convergence

- The maximum period for multicast protocol convergence can be specified on each device unless otherwise specified.

↘ Configuring the Multicast Packet Leakage Period

- The multicast leakage period can be configured on each device unless otherwise specified.

Verification

Run **show msf nsf** to check the configured multicast non-stop forwarding parameters.

Related Commands

↘ Configuring the Maximum Period for Multicast Protocol Convergence

Command	msf nsf convergence-time <i>time</i>
Parameter Description	convergence-time <i>time</i> : Specifies the maximum period for multicast protocol convergence. The value ranges from 0 to 3600s. The default value is 20s.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring the Multicast Packet Leakage Period

Command	msf nsf leak <i>interval</i>
Parameter Description	leak <i>interval</i> : Specifies the multicast packet leakage period. The value ranges from 0 to 3600s. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	-

↘ Displaying Multicast Non-Stop Forwarding Configurations

Command	show msf nsf
Parameter Description	-
Command Mode	Privilege, global and interface configuration modes
Usage Guide	-

Configuration Example

↘ Creating the IP Multicast Service on the IPv4 Network and Supporting PIM-DM

Scenario	Basic environment of the IP multicast service (Omitted)
-----------------	---

Configuration Steps	<ul style="list-style-type: none"> ● Configure the basic functions of IP multicast. (Omitted) ● Configure the maximum period for multicast protocol convergence. ● Configure the multicast packet leakage period.
A	<pre>A# configure terminal A(config)# msf nsf convergence-time 200 A(config)# msf nsf leak 300</pre>
Verification	Run show msf nsf to display multicast non-stop forwarding configurations.
A	<pre>A# show msf nsf Multicast HA Parameters -----+-----+ protocol convergence timeout 200 secs flow leak interval 300 secs</pre>

1.4.9 Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Configuration Effect

- Delete the earliest hardware entries and adds new entries if the hardware forwarding table overflows when you create multicast forwarding entries.

Notes

- The basic functions of IP multicast must be configured.

Configuration Steps

- The overwriting mechanism upon overflow of multicast hardware forwarding entries can be configured on each device unless otherwise specified.

Verification

Run **show running-config** to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.

Related Commands

- ↘ [Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries](#)

Command	msf ipmc-overflow override
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

Configuration Example

Creating the IP Multicast Service on the IPv4 Network and Configuring an Overwriting Mechanism Upon Overflow of Multicast Hardware Forwarding Entries

Scenario	Basic environment of the IP multicast service (Omitted)
Configuration Steps	<ul style="list-style-type: none"> Configure the basic functions of IP multicast. (Omitted) Configure the overwriting mechanism upon overflow of multicast hardware forwarding entries.
A	<pre>A# configure terminal A(config)#msf ipmc-overflow override</pre>
Verification	Run show running-config to check whether the overwriting mechanism upon overflow of multicast hardware forwarding entries is configured.
A	<pre>A# show running-config ... msf ipmc-overflow override ...</pre>

1.5 Monitoring

Displaying

Description	Command
Displays the IPv4 multi-layer multicast forwarding table.	show msf msc

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the processing of IPv4 multi-layer multicast packet forwarding.	debug msf forwarding
Debugs the operation on multi-layer multicast forwarding entries on an IPv4 network.	debug msf mfc
Debugs the bottom-layer hardware processing of IPv4 multi-layer multicast packet forwarding.	debug msf ssp
Debugs the invocation of API interfaces provided by IPv4 multi-layer multicast forwarding.	debug msf api
Debugs the processing of multi-layer multicast forwarding events on an IPv4 network.	debug msf event

2 Configuring IPv6 Multicast

2.1 Overview

IPv6 multicast is enrichment and enhancement of IPv4 multicast. In comparison with IPv4 multicast, the IPv6 multicast address mechanism is greatly enriched.

In traditional IP transmission, a host is allowed to send packets only to a single host (unicast communication) or all hosts (broadcast communication). The multicast technology provides a third choice: A host is allowed to send packets to certain hosts.

The IP multicast technology is applicable to one-to-many multimedia applications.

Protocols and Standards

IPv6 multicast covers the following protocols:

- Multicast Listener Discovery (MLD): Runs between a multicast device and a host, and tracks and learns relationships of group members.
- Protocol Independent Multicast – Sparse Mode for IPv6 (PIM-SMv6): Runs between devices and implements multicast packet forwarding by establishing a multicast routing table.

2.2 Applications

Application	Description
Typical Application of PIM-SMv6	The PIM-SMv6 multicast service is provided in the same network.

2.2.1 Typical Application of PIM-SMv6

Scenario

The PIM-SMv6 multicast service is provided in the same network.

As shown in the following figure:

- R1 and the multicast source are in the same network, R2 is configured as a rendezvous point (RP), R3 is in the same network as Receiver A, and R4 is in the same network as Receiver B. Assume that devices and hosts are correctly connected, IPv6 is enabled on each interface, and IPv6 unicast is enabled on each device.

Figure 2-1

Remarks	<p>R1, R2, R3, and R4 are Layer-3 devices and R2 functions as an RP.</p> <p>The multicast source is directly connected to R1, Receiver A is directly connected to R3, and Receiver B is directly connected to R4.</p>
----------------	---

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the same network to implement unicast routing.
- Run the PIM-SMv6 protocol in the same network to implement multicast routing.

2.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

↘ (*,G), (S,G)

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

↘ ASM, SSM

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.
- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.

i SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Configuring IPv6 Multicast Basic Functions	Creates a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	Restricts the number of entries that can be added to the multicast routing table.

Feature	Description
Configuring the IPv6 Multicast Border	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	Configures multicast static routing to adopt multicast forwarding paths different from unicast forwarding paths.
Configuring Layer-2 Flow Direction Control for Multicast Streams	Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast stream.
Configuring RPF Route Selection According to the Longest Matching Principle	One optimal route is selected from each of the multicast static routing table, MBGP routing table, and unicast routing table according to RPF rules. Among the three optimal routes, the route with the longest subnet mask matching is selected as the RPF route.

2.3.1 Configuring IPv6 Multicast Basic Functions

Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

Working Principle

A device maintains the routing table used for multicast packet forwarding over an IPv6 multicast routing protocol (such as PIM-SMv6), and learns information about the status of group members in the directly-connected network segments over the MLDv1/v2 protocol. A host joins a specific IPv6 multicast group by transmitting the MLD REPORT message.

Related Configuration

▾ Enabling the IPv6 Multicast Routing Function

The IPv6 multicast routing function is disabled by default.

Run the **ipv6 multicast-routing** command to enable the IPv6 multicast routing function.

▾ Configuring an IP Multicast Protocol on an Interface

The IPv6 multicast protocol is disabled on an interface by default.

Run the **ipv6 pim dense-mode** command to enable the IPv6 multicast protocol on an interface.

2.3.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Working Principle

Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements, so as to sustain the device performance.

Related Configuration

Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

By default, 1,024 entries can be added to the IP multicast routing table.

Run the **ipv6 multicast route-limit** *limit* [*threshold*] command to adjust the number of entries that can be added to the IPv6 multicast routing table. The value ranges from 1 to 65,536.

A larger value of *limit* means that more entries can be added to the IPv6 multicast routing table, and a smaller value of *limit* means that fewer entries can be added to the IPv6 multicast routing table.

2.3.3 Configuring the IPv6 Multicast Border

Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Working Principle

Configure the multicast border to specify the transmission scope of multicast packets. When the multicast forwarding border is configured on an interface, multicast packets including multicast packets sent by the local device cannot be forwarded or received by this interface.

Related Configuration

Configuring the IPv6 Multicast Border

No multicast border is configured by default.

Run the **ipv6 multicast boundary** *access-list-name* [*in* | *out*] command to configure the multicast border.

2.3.4 Configuring IPv6 Multicast Static Routing

Configure IPv6 multicast static routing to specify a reverse path forwarding (RPF) interface or RPF neighbor for multicast packets from a specific multicast source.

Working Principle

The RPF check is conducted during forwarding of multicast packets. IPv6 multicast static routing can be configured to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Related Configuration

Configuring IPv6 Multicast Static Routing

No multicast static routing is configured by default.

Run the **ipv6 mroute** *ipv6-prefix/prefix-length* [**bgp** | **isis** | **ospfv3** | **ripng** | **static**] { *ipv6-prefix* | *interface-type interface-number* } [*distance*] command to configure IPv6 multicast static routing.

2.3.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Working Principle

Configure Layer-2 flow direction control for multicast streams to configure the ports that are allowed to forward multicast streams. Then, multicast streams are forwarded only by the configured ports, thereby controlling Layer-2 forwarding of multicast streams.

Related Configuration

↳ Configuring Layer-2 Flow Direction Control for Multicast Streams

Layer-2 flow direction control is disabled for multicast streams by default.

Run the **ipv6 multicast static** *source-address group-address interface-type interface-number* command to configure the Layer-2 flow direction control for multicast streams.

2.3.6 Configuring RPF Route Selection According to the Longest Matching Principle

Among the three optimal routes selected from the multicast static routing table, Multiprotocol Border Gateway Protocol (MBGP) routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Working Principle

According to RPF rules, select a multicast static route, MBGP route, and unicast route used for the RPF check respectively from the multicast static routing table, MBGP routing table, and unicast routing table.

- If route selection according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.
- If route selection according to the longest matching principle is not configured, the route with the highest priority is selected. If the three routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Related Configuration

↳ Configuring RPF Route Selection According to the Longest Matching Principle

A route with the highest priority is selected as the RPF route by default. If the routes have the same priority, the RPF route is selected according to the sequence of multicast static route, MBGP route, and unicast route.

Run the **ipv6 multicast rpf longest-match** command to configure RPF route selection according to the longest matching principle.

2.4 Configuration

Configuration	Description and Command	
Configuring IPv6 Multicast Basic Functions	⚠ (Mandatory) It is used to create a multicast service.	
	ipv6 multicast-routing	Enables the IPv6 multicast routing function.
Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table	⚠ Optional.	
	ipv6 multicast route-limit limit [threshold]	Restricts the number of entries that can be added to the multicast routing table.
Configuring the IPv6 Multicast Border	ipv6 multicast boundary access-list-name [in out]	Sets an interface as the multicast border of a specific group range.
Configuring IPv6 Multicast Static Routing	ipv6 mroute ipv6-prefix/prefix-length [protocol] { v6rpf-address interface-type interface-number } [distance]	Configures IPv6 multicast static routing.
Configuring Layer-2 Flow Direction Control for Multicast Streams	ipv6 multicast static source-address group-address interface-type interface-number	Controls the flow direction of data streams on Layer-2 ports.
Configuring RPF Route Selection According to the Longest Matching Principle	ipv6 multicast rpf longest-match	Configures RPF route selection according to the longest matching principle.

2.4.1 Configuring IPv6 Multicast Basic Functions

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.

Notes

- The PIM network needs to use existing unicast routing in the network. Therefore, IPv6 unicast routing must be configured in the network.

Configuration Steps

↳ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- Enable the IPv6 multicast routing function on each router unless otherwise specified.

▾ Enabling an IP Multicast Protocol on Interfaces

- Mandatory.
- Enable the IPv6 multicast protocol function on interfaces unless otherwise specified.

Verification

Make multicast sources in the network send multicast packets and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.

Related Commands

▾ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The IPv6 multicast routing function must be enabled before various IPv6 multicast protocols are enabled. The IPv6 multicast routing function and the MLD snooping function are mutually exclusive.

▾ Configuring IPv6 Multicast Protocols

- i** For details about the MLD configuration method, see the *Configuring MLD*.
- i** For details about the PIM-SMv6 configuration method, see the *Configuring PIM-SMv6*.
- i** After the Layer-3 multicast function is enabled on a private VLAN and Super VLAN, if there is a multicast source in the sub-VLAN, an entry needs to be additionally copied, with the inlet of the sub-VLAN where multicast streams enter because the validity check needs to be conducted at the inlet during multicast packet forwarding. As a result, one more multicast hardware entry is occupied, and the multicast capacity needs to be decreased by one.

▾ Displaying Multicast Forwarding Table Information

Command	show ipv6 mroute [group-or-source-address [group-or-source-address]] [sparse] [summary count]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. <i>group-or-source-address</i> : Indicates the group address or source address. sparse : Displays the core entry of the PIM-SMv6 multicast routing table. summary : Displays the summary of IPv6 multicast routing entries. count : Displays the count information about IPv6 multicast routing entries.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode

Usage Guide	N/A
--------------------	-----

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network to Support PIMv6-SM

<p>Scenario</p> <p>Figure 2-2</p>	 <p>The diagram illustrates a network topology for IPv6 multicast. A Source is connected to Router A via interface Gi0/1. Router A is connected to Router B via interface Gi0/2. Router B is connected to Receiver A via interface Gi0/1.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an IPv6 unicast routing protocol (for example, OSPFv3) on routers. ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIMv6-SM function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source.
<p>A</p>	<pre>A# configure terminal A(config)# ipv6 multicast-routing A(config)# interface gigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode A(config-if)# exit A(config)# interface gigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode A(config-if)# exit</pre>
<p>B</p>	<pre>B# configure terminal B(config)# ipv6 multicast-routing B(config)# interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode B(config-if)# exit</pre>

<p>Verification</p>	<p>Make Multicast Source (2001::1) send packets to G(ff16::16) and make Receiver A join G.</p> <ul style="list-style-type: none"> ● Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from G. ● Check the multicast forwarding table on Receiver A and Device B.
<p>A</p>	<pre>A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:03:12, stat expires 00:02:03 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2</pre>
<p>B</p>	<pre>B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:23, stat expires 00:03:07 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- No IPv6 multicast protocol is enabled on an interface.

2.4.2 Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

Configuration Effect

- Every multicast data packet received by the device is used to maintain relevant IPv6 multicast routing entries. Excessive multicast routing entries, however, may deplete the device memory and degrade the device performance. Users can restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Restrict the number of entries in the IPv6 multicast routing table based on the actual networking conditions and service performance requirements.

Verification

Make multicast sources in the network send multicast packets to N different multicast groups and make a user host join these groups. Set the number of entries that can be added to the IPv6 multicast routing table to N-1 on the device and check that multicast packets received by the user host are from N-1 groups.

Related Commands

📄 Configuring the Number of Entries That Can Be Added to the IP Multicast Routing Table

Command	<code>ipv6 multicast route-limit <i>limit</i> [<i>threshold</i>]</code>
Parameter Description	<p><i>limit</i>: Indicates the number of multicast routing entries. The value ranges from 1 to 65,536 and the default value is 1,024.</p> <p><i>threshold</i>: Indicates the multicast routing entry quantity for triggering an alarm. The default value is 65,536.</p>
Command Mode	Global configuration mode
Usage Guide	Routing entries that are beyond the allowable range of hardware can be forwarded only by software due to hardware resource restrictions, making the performance deteriorate.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the Number of Entries That Can Be Added to the IPv6 Multicast Routing Table

<p>Scenario Figure 2-3</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure IP multicast basic functions (omitted). Set the number of entries that can be added to the IP multicast routing table to 2 on Device B.
<p>B</p>	<pre>B# configure terminal B(config)# ipv6 multicast route-limit 2</pre>
<p>Verification</p>	<p>Make Multicast Source (2001: : 1) send packets to G1(ff16::16), G2(ff16::17), and G3(ff16::18) and make Receiver A join G1, G2, and G3.</p> <ul style="list-style-type: none"> Check multicast packets received by Receiver A. Receiver A should be able to receive multicast packets from two groups of G1, G2, and G3. Check multicast routing entries on Receiver A and Device B. A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.
<p>A</p>	<pre>A# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:01:01, stat expires 00:02:29</pre>

	<pre> Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (2001::1, ff16::17), uptime 00:01:01, stat expires 00:02:29 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 (2001::1, ff16::18), uptime 00:00:57, stat expires 00:02:33 Owner PIMSMV6, Flags: TFS Incoming interface: GigabitEthernet 0/1 Outgoing interface list: GigabitEthernet 0/2 </pre>
B	<pre> B# show ipv6 mroute IPv6 Multicast Routing Table Flags: I - Immediate Stat, T - Timed Stat, F - Forwarder installed, R - RPT, S - SPT, s - SSM Group Timers: Uptime/Stat Expiry Interface State: Interface (2001::1, ff16::16), uptime 00:00:29, stat expires 00:03:01 Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1 (2001::1, ff16::17), uptime 00:00:29, stat expires 00:03:01 </pre>

	<pre>Owner PIMSMV6, Flags: TFR Incoming interface: GigabitEthernet 0/2 Outgoing interface list: GigabitEthernet 0/1</pre>
	<p>A prompt is displayed when the number of entries in the multicast routing table reaches the upper limit.</p> <pre>B##* Jan 3 21:40:07: %MROUTE-4-ROU TELIMIT: IPv6 Multicast route limit 2 exceeded..</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.3 Configuring the IPv6 Multicast Border

Configuration Effect

- Configure the IPv6 multicast border to restrict the transmission scope of multicast packets.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure the IPv6 multicast border on each PIM router interface unless otherwise specified.

Verification

Make multicast sources send multicast packets to multicast groups and make a user host join these multicast groups. Configure the IPv6 multicast border on the PIM router interface connected to the user host and check whether the user host can receive multicast packets.

Related Commands

↳ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast boundary <i>access-list-name</i> [in out]
Parameter Description	<p><i>access-list-name</i>: Uses the group address range defined by an access control list (ACL).</p> <p>in: Indicates that the multicast border takes effect in the incoming direction of multicast streams.</p> <p>out: Indicates that the multicast border takes effect in the outgoing direction of multicast streams.</p>
Command Mode	Interface configuration mode
Usage Guide	The ACL referenced in this command can be a standard ACL or an extended ACL. If an extended ACL is used, only destination addresses need to be matched.

This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not transmitted or received by multicast border interfaces.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring the IPv6 Multicast Border

<p>Scenario Figure 2-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IP multicast basic functions (omitted). ● Configure an ACL on Device A. ● Configure the IP multicast border on Interface Gi0/1 of Device A.
<p>A</p>	<pre>A# configure terminal A(config)# ipv6 access-list ip_multicast A(config-ipv6-acl)#deny udp any any A(config-ipv6-acl)#exit A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#ip multicast boundary ip_multicast A A(config-if-GigabitEthernet 0/1)# exit</pre>
<p>Verification</p>	<p>Make Multicast Source (192.168.1.100) send packets to G (233.3.3.3) and make Receiver A join G.</p> <ul style="list-style-type: none"> ● Run the debug ipv6 pim sparse-mode events command to debug multicast events in SM mode.
<p>A</p>	<pre>A# debug ipv6 pim sparse-mode events Dec 28 11:54:07: %7: No cache message: src 2001::1 for ff16::16 vif 1 *Dec 28 11:54:07: %7: Ignore No cache message: src 2001::1 for ff16::16 vif 1 in PIM6_BOUNDARY_FLT_BOTH range</pre>

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.4 Configuring IPv6 Multicast Static Routing

Configuration Effect

- Configure IPv6 multicast static routing to specify an RPF interface or RPF neighbor for multicast packets from a specific multicast source.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure IPv6 multicast static routing on each device unless otherwise specified.

Verification

Configure IPv6 multicast static routing and then run the **show ipv6 rpf v6source-address** command to check RPF information about a specific multicast source.

Related Commands

↳ Configuring IPv6 Multicast Static Routing

Command	ipv6 mroute <i>ipv6-prefix/prefix-length</i> [<i>protocol</i>] { <i>v6rpf-address</i> <i>interface-type interface-number</i> } [<i>distance</i>]
Parameter Description	<p><i>ipv6-prefix</i>: Indicates the IPv6 address of a multicast source.</p> <p><i>prefix-length</i>: Indicates the subnet mask of the IPv6 address of the multicast source.</p> <p>fallback-lookup { global vrf <i>vrf-name</i> }: Specifies the VRF used for RPF search.</p> <p><i>protocol</i>: Indicates the unicast routing protocol that is being used currently.</p> <p><i>v6rpf-address</i>: Indicates the IPv6 address of the RPF neighbor (next hop to the multicast source).</p> <p><i>interface-type interface-number</i>: Indicates the RPF interface (outbound interface to the multicast source).</p> <p><i>distance</i>: Indicates the route management distance. The value ranges from 0 to 255 and the default value is 0.</p>
Command Mode	Global configuration mode
Usage Guide	<p>IPv6 multicast static routing is used only for the RPF check.</p> <p>To specify the outbound interface rather than the next-hop IP address of IPv6 static multicast routing, the outbound interface must be of the point-to-point type.</p>

↳ Displaying RPF Information About a Specific Source Address

Command	show ipv6 rpf <i>v6source-address</i>
Parameter	<i>v6source-address</i> : Indicates the IPv6 source address.

Description	
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring IPv6 Multicast Static Routing

<p>Scenario Figure 2-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure IPv6 multicast basic functions (omitted). Configure a static route to the receiver on Device B.
<p>A</p>	<pre>B# configure terminal B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2</pre>
<p>Verification</p>	<p>Run the show ipv6 rpf command to display the RPF information received by the receiver before and after configuration.</p>
<p>Before Configuration</p>	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1 RPF neighbor: fe80::2d0:f8ff:fe22:341b RPF route: 2005::1/128 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
<p>After Configuration</p>	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2</pre>

```

RPF neighbor: 2002::2
RPF route: 2005::/64
RPF type: unicast (ospf)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 110
Metric: 1

```

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.

2.4.5 Configuring Layer-2 Flow Direction Control for Multicast Streams

Configuration Effect

Configure Layer-2 flow direction control for multicast streams to control the forwarding behavior of multicast streams on ports.

Notes

- The IPv6 multicast basic functions must be configured.

Configuration Steps

- Configure Layer-2 flow direction control for multicast streams on devices unless otherwise specified.

Verification

Make Device A send multicast packets to multicast groups in the network. Multiple user hosts connected to VLAN 1 of Device A receive multicast packets from these multicast groups. Configure Layer-2 flow direction control for multicast streams on Device A so that multicast packets are sent to configured ports.

Related Commands

📄 Configuring Layer-2 Flow Direction Control for Multicast Streams

Command	ipv6 multicast static <i>source-address group-address interface-type interface-number</i>
Parameter Description	<i>source -address</i> : Indicates the multicast source address. <i>group-address</i> : Indicates the multicast group address. <i>interface-type interface-number</i> : Indicates a Layer-2 port that is allowed to forward multicast streams.
Command Mode	Global configuration mode

Usage Guide	<p>Multiple commands can be configured for a multicast stream, that is, multiple ports can be allowed to forward the multicast stream. If flow direction control is configured for a multicast stream, the multicast stream can be forwarded only by the configured ports. Other ports are not allowed to forward the multicast stream.</p> <p>This command controls only the forwarding behavior of multicast streams on ports. It does not directly affect processing of protocol packets by multicast protocols. Some features of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.</p>
--------------------	---

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network and Configuring Layer-2 Flow Direction Control for Multicast Streams

<p>Scenario Figure 2-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure IP multicast basic functions (omitted). Configure Layer-2 flow direction control for multicast streams on Device B so that multicast streams are transmitted only to Interface Gi0/2.
<p>B</p>	<pre>A# configure terminal A(config)# ipv6 multicast static 2001::1 ff16::16 gigabitEthernet 0/2</pre>
<p>Verification</p>	<p>Make Multicast Source (2001: : 1) send packets to G (ff16::16) and make Receiver A and Receive B join G.</p> <ul style="list-style-type: none"> Receiver A should be able to receive multicast packets from G but Receiver B cannot receive multicast packets from G.

Common Errors

- IPv6 unicast routing is incorrectly configured.

2.4.6 Configuring RPF Route Selection According to the Longest Matching Principle

Configuration Effect

Among the three optimal routes selected from the multicast static routing table, MBGP routing table, and unicast routing table, select the optimal route with the longest subnet mask matching as the RPF route.

Notes

- The IP multicast basic functions must be configured.

Configuration Steps

- Configure RPF route selection according to the longest matching principle on each device unless otherwise specified.

Verification

Configure a multicast static route and a unicast static route with the same priority and configure the unicast static route to have the longest subnet mask matching.

- Run the **show ipv6 rpf v6source-address** command to check RPF information about a specific source.

Related Commands

↳ Configuring RPF Route Selection According to the Longest Matching Principle

Command	ipv6 multicast rpf longest-match
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>The steps of selecting an RPF route are as follows:</p> <p>Select one optimal route used for the RPF check from each of the IPv6 multicast static routing table, IPv6 MBGP routing table, and IPv6 unicast routing table.</p> <p>Select one route out of the three optimal routes as the RPF route.</p> <p>If the command for selecting the RPF route according to the longest matching principle is configured, the route with the longest subnet mask matching is selected out of the three optimal routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route.</p> <p>If the command for selecting the RPF route according to the longest matching principle is not configured, the route with the highest priority is selected out of the three optimal routes as the RPF route. If the routes have the same priority, the RPF route is selected according to the sequence of IPv6 multicast static route, IPv6 MBGP route, and IPv6 unicast route.</p>

Configuration Example

Creating the IPv6 Multicast Service on the IPv6 Network and Configuring the RPF Route Selection According to the Longest Matching Principle

Scenario Figure 2-7	
Configuration Steps	<ul style="list-style-type: none"> ● Configure IP multicast basic functions (omitted). ● Configure an IPv6 multicast static route with the subnet mask length smaller than that of the unicast route on Device B. ● Configure the RPF route selection according to the longest matching principle on Device B.
B	<pre>B# configure terminal B(config)# ipv6 multicast-routing B(config)# ipv6 mroute 2005::/64 ospfv3 2002::2 B(config)# ipv6 multicast rpf longest-match</pre>
Verification	<p>Run the show ipv6 rpf command to display the RPF information about the multicast source before and after RPF route selection according to the longest matching principle is configured.</p>
Before Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/2 RPF neighbor: 2002::2 RPF route: 2005::/64 RPF type: unicast (ospf) RPF recursion count: 0 Doing distance-preferred lookups across tables Distance: 110 Metric: 1</pre>
After Configuration	<pre>B# show ipv6 rpf 2005::1 RPF information for 2005::1 RPF interface: GigabitEthernet 0/1</pre>

```

RPF neighbor: fe80::2d0:f8ff:fe22:341b
RPF route: 2005::1/128
RPF type: unicast (ospf)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 110
Metric: 1

```

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.

2.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the IPv6 multicast forwarding table.	clear ipv6 mroute { * <i>v6group-address</i> [<i>v6source-address</i>] }
Clears the statistics in the IPv6 multicast forwarding table.	clear ipv6 mroute statistics { * <i>v6group-address</i> [<i>v6source-address</i>] }

Displaying

Description	Command
Displays the IPv6 multicast forwarding table information.	show ipv6 mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [sparse] [summary count]
Displays RPF information about a specific IPv6 source address.	show ipv6 rpf <i>v6source-address</i>
Displays information the IPv6 static multicast route.	show ipv6 mroute static
Displays information about the configured IPv6 multicast interface that takes effect.	show ipv6 mvif [<i>interface-type interface-number</i>]
Displays the IPv6 Layer-3 multicast forwarding table.	show ipv6 mrf mfc

Displays the IPv6 multi-layer multicast forwarding table.	show msf6 msc
---	----------------------

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all running processes of the IPv6 multicast.	debug nsm mcast6 all
Debugs the communication between the IPv6 multicast and the protocol module.	debug nsm mcast6 fib-msg

Debugs the APIs for IPv6 multi-layer multicast forwarding.	debug msf6 api
Debugs the processing of IPv6 multi-layer multicast forwarding events.	debug msf6 event

3 Configuring IGMP

3.1 Overview

The Internet Group Management Protocol (IGMP) is a member of TCP/IP protocol family. It manages IP multicast members and is used to establish and maintain multicast group membership between hosts and directly neighboring multicast routers. IGMP behaviors are classified into host behaviors and device behaviors.

- At present, three IGMP versions are available, which are IGMPv1, IGMPv2 and IGMPv3.
- All IGMP versions support the Any-Source Multicast (ASM) model.
- IGMPv3 can be directly used for the Source-Specific Multicast (SSM) model.
- IGMPv1 and IGMPv2 can be used for the SSM model only when the IGMP SSM Mapping technology is supported.

Protocols and Standards

- RFC 1112: Host Extensions for IP Multicasting
- RFC 2236: Internet Group Management Protocol, Version 2
- RFC 3376: Internet Group Management Protocol, Version 3
- RFC 4605: Internet Group Management Protocol (IGMP) / Multicast Listener Discovery (MLD)-Based Multicast Forwarding ("IGMP/MLD Proxying")

3.2 Applications

Application	Description
Local IGMP Service	Implements the IGMP service in a local network.
IGMP Proxy Service	In a simple tree network topology, use the IGMP proxy service instead of the PIM service.

3.2.1 Local IGMP Service

Scenario

As shown in Figure 3-1, receivers 1 and 2 and routers A and B form a local network.

Query packets sent by router A or B are valid in the LAN, whereas Report packets sent by receivers 1 and 2 are also valid locally.

Figure 3-1

Remarks	C is the egress gateway (EG) device. A and B are core routers.
----------------	---

Deployment

- Routers A, B and C run OSPF.
- The interfaces of A, B and C run multicast protocols (PIM-SM or PIM-DM).

3.2.2 IGMP Proxy Service

Scenario

As shown in Figure 3-2, router A implements the proxy function working as a host and forms a local network group with router B. Router A forwards Report packets sent by receivers 1 and 2.

Figure 3-2

Remarks	Router A implements the proxy function. Router B provides the PIM service.
----------------	---

Deployment

- Routers A and B run OSPF.
- The interfaces of A and B run multicast protocols (PIM-SM or PIM-DM).
- The multicast proxy function is implemented on the interfaces Gi0/0 and Gi0/1 of router A.

3.3 Features

Basic Concepts

Host Behavior and Device Behavior

- Layer-3 multicast devices that run multicast management protocols are called devices and their behaviors are called device behaviors.
- PCs or simulated PCs that run multicast management protocols are called hosts and their behaviors are called host behaviors.

Querier

- Devices compete against each other by comparing IP addresses. Devices with lower IP addresses become queriers and send Query packets regularly.

IGMP Proxy-Service Interface

- This interface performs host behaviors, receives Query packets sent by upstream devices (hence also called uplink interface), and sends Report information collected by the router proxy.

IGMP Mroute-Proxy Interface

- This interface implements the router functions, sends packets received by the IGMP PROXY-SERVICE interface (hence also called downlink interface), and collects host information and sends the host information to the IGMP PROXY-SERVICE interface.

IGMP SSM Mapping

- Mapping of the SSM model. IGMPv1 and IGMPv2 do not support the SSM model, but can enable the SSM-MAP function to support the SSM model.

Overview

Feature	Description
IGMP Router	Sends Query packets and obtains local member information.
IGMP Group Filtering	Filters group members and limit the number of group members.
Static IGMP Group	Static group information is available on a router; therefore, it is unnecessary for the host to send a Report packet to obtain the static group information.
Simulating Hosts to Join IGMP Groups	Simulates the host behavior to directly join a multicast group on an interface.
IGMP Proxy	Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed.

Feature	Description
IGMP SSM Mapping	Provides the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.
Router Alert Option	Checks whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option. Sends IGMP packets with the Router Alert option.

3.3.1 IGMP Router

- This function is used to send Query packets and obtain local member information.

Working Principle

- In a multicast network running the IGMP, a multicast device periodically sends IGMP Query packets and confirms information about local members based on responses.
- Only one multicast device sends IGMP Query packets in one network segment and this device is called querier. The querier is determined by means of selection. Initially, all multicast devices are in the Querier state. When a device receives a membership query from a device with a lower IP address, the device changes from the Querier state to the Non-querier state. Therefore, only one device is in the Querier state finally. This device has the lowest IP address among all multicast devices in the network.
- The querier sends IGMP packets of different versions based on the IGMP version settings. In addition, the following querier parameters can be modified: frequency for the querier to send IGMP Query packets, query times and query interval for the last member, maximum response time of IGMP Query packets, and keepalive time of the existing querier.

Related Configuration

↘ Enabling IGMP

IGMP is disabled on an interface by default.

You can run the **ip pim { sparse-mode| dense-mode }** command to enable or disable IGMP for an interface.

IGMP can be enabled only when Sparse Mode (SM) or Dense Mode (DM) is configured on the interface.

↘ Specifying the IGMP Version

IGMPv2 is enabled by default.

You can run the **ip igmp version { 1 | 2 | 3 }** command to set or reset the IGMP version.

↘ Configuring the Last-Member Query Interval

The interval for sending the last-member Query packets is 1s by default.

You can run the **ip igmp last-member-query-interval** *interval* command to set or reset the interval for an interface to send Query packets.

A larger value means a larger interval; a smaller value means a smaller interval.

↘ **Configuring the Last-Member Query Times**

The number of the last-member query times is 2 by default.

You can run the **ip igmp last-member-query-count** *count* command to set or reset the number of the last-member query times.

A larger value means more last-member query times; a smaller value means fewer last-member query times.

↘ **Configuring the Common Member Query Interval**

The common member query interval is 125s by default.

You can run the **ip igmp query-interval** *seconds* command to set or reset the common member query interval.

A larger value means a larger common query interval; a smaller value means a smaller common query interval.

↘ **Configuring the Maximum Response Time**

The maximum response time is 10s by default.

You can run the **ip igmp query-max-response-time** *seconds* command to set or reset the maximum response time.

A larger value means longer response time; a smaller value means shorter response time.

↘ **Configuring the Querier Timeout**

The querier timeout is 255s by default.

You can run the **ip igmp query-timeout** *seconds* command to set the querier timeout.

A larger value means longer survival time; a smaller value means shorter survival time.

3.3.2 IGMP Group Filtering

Filter group members and limit the number of group members.

Working Principle

To prevent hosts in a network segment where an interface resides from joining a multicast group, you can configure an ACL on this interface as a filter. The interface will filter the received IGMP membership Report packets based on this ACL, maintain group membership only for multicast groups allowed by this ACL and set the maximum number of router members.

Related Configuration

↘ **Configuring the IGMP Group ACL**

By default, no ACL is used and any group is allowed to join.

You can run the **ip igmp access-group** *access-list-name* command to set or reset the multicast group ACL.

After the ACL is configured, a router receives only packets set in the ACL.

↘ [Configuring the Maximum Number of IGMP Group Members](#)

The maximum number of IGMP group members is 1,024 by default.

You can run the **ip igmp limit *number*** command to set or reset the maximum number of multicast group members.

A larger value means more members; a smaller value means fewer members.

3.3.3 Static IGMP Group

When static IGMP groups are available on a router, it is unnecessary for the host to send a Report packet to obtain the static group information. The router can directly exchange group information with a PIM router.

[Working Principle](#)

You need to set static group information manually.

[Related Configuration](#)

↘ [Configuring a Static Group](#)

No static group is configured by default.

You can run the **ip igmp static-group *group-address*** command to configure a static group.

3.3.4 Simulating Hosts to Join IGMP Groups

Simulate the host behavior to directly join a multicast group on an interface.

[Related Configuration](#)

↘ [Configuring the Join-Group function](#)

No join-group information is set by default.

You can run the **ip igmp join-group *group-address*** command to configure the address of the multicast group to be joined by the simulated host.

3.3.5 IGMP Proxy

Use this function in a simple tree network topology where no complex multicast route protocols (such as PIM) need to be executed. In this way, a downstream proxy host can send IGMP packets and maintain the membership.

[Working Principle](#)

When an upstream router is configured as an IGMP proxy-service interface, it is equal to a host that can receive Query packets sent by upstream routers or forward group information sent by downstream hosts. When a downstream router is configured as an IGMP multicast proxy interface, it is equal to a router that can forward Query packets sent by upstream routers or receive Report packets sent by downstream routers.

Related Configuration

▾ Configuring the IGMP Proxy Service

The IGMP proxy service function is disabled by default.

You can run the **ip igmp proxy-service** command to enable the IGMP proxy service.

This function is mandatory when a proxy is to be used.

▾ Configuring the IGMP Mroute Proxy

The IGMP mroute proxy function is disabled by default.

You can run the **ip igmp mroute-proxy** *interfacename* command to enable the IGMP mroute proxy.

This function is mandatory when a proxy is to be used.

3.3.6 IGMP SSM Mapping

Provide the SSM model support for IGMPv1 and IGMPv2. When a host joins a group, you can specify a source to save bandwidth and prevent unwanted and invalid multicast data streams from occupying network bandwidth, especially in a network environment where multiple multicast sources share one multicast address.

Working Principle

Based on IGMP v1/v2, IGMPv3 provides an extra function, namely, the multicast source filter function. In IGMPv1/v2, a host determines to join a group only based on the group address and then receive multicast streams sent to this group address from any source. A host using IGMPv3 advertises the multicast group that the host wants to join and the addresses of multicast sources from which this host wants to receive packets. IGMPv1 and IGMPv2 also implement "source address filtering" in some sense; however, they implement this function on the multicast receivers by enabling the SSM mapping function and configuring the static SSM mapping group.

Related Configuration

▾ Enabling IGMP SSM Mapping

The SSM mapping function is disabled by default.

You can run the **ip igmp ssm-map enable** command to enable the function.

▾ Configuring Static IGMP SSM Mapping

No static SSM mapping is set by default.

You can run the **ip igmp ssm-map static** *access-list-num A.B.C.D* command to configure static SSM mapping.

3.3.7 Router Alert Option

Check whether IGMP packets contain the Router Alert option and discard packets without the Router Alert option.

Support sending IGMP packets containing the Router Alert option.

Working Principle

If a packet contains the Router Alert option, the device needs to check the packet in depth and updates the control data accordingly. If the packet does not contain the option, the device does not check the packet.

After Router Alert option check is enabled, the IGMP packets not containing the Router Alert option are discarded.

After enabled with the function of sending packets with Router Alert option, the device sends IGMP packets with Router Alert option encapsulated.

Related Configuration

▾ Checking Router Alert Option

Router Alert option check is disabled by default.

You can run the **ip igmp enforce-router-alert** command to enable the function.

▾ Sending IGMP Packets with Router Alert Option Encapsulated

Packets are sent without the Router Alert option by default.

You can run the **ip igmp send-router-alert** command to enable the function.

3.4 Configuration

Configuration	Description and Command	
Configuring IGMP Basic Functions	 (Mandatory) It is used to set up the multicast service.	
	ip multicast-routing	Enables the IPv4 multicast routing function.
	ip pim { sparse-mode dense-mode }	Enables the PIM-SM or PIM-DM function.
Configuring IGMP Routers	ip igmp version { 1 2 3 }	Specifies the IGMP version.
	ip igmp last-member-query-interval interval	Configures the last-member query interval.
	ip igmp last-member-query-count count	Configures the last-member query times.
	ip igmp query-interval seconds	Configures the membership query interval.
	ip igmp query-max-response-time seconds	Configures the maximum response time.
Configuring IGMP Group Filtering	ip igmp query-timeout seconds	Configures the querier timeout.
	ip igmp access-group access-list	Configures the IGMP group ACL.
Configuring IGMP Proxy	ip igmp limit number [except access-list]	Configures the maximum number of IGMP group members.
	ip igmp proxy-service	Configures the IGMP proxy service.

	ip igmp mroute-proxy <i>interface-type</i> <i>interface-number</i>	Configures the IGMP mroute proxy.
Configuring IGMP SSM Mapping	ip igmp ssm-map enable	Enables IGMP SSM mapping.
	ip igmp ssm-map static <i>access-list</i> <i>source-address</i>	Configures static IGMP SSM mapping.
Configuring Alert Option	ip igmp enforce-router-alert	Checks the Router Alert option.
	ip igmp send-router-alert	Sends IGMP packets containing the Router Alert option.

3.4.1 Configuring IGMP Basic Functions

Configuration Effect

- Enable the multicast routing function of a local network and collect group information of the local network.

Notes

- An interface must be enabled with the PIM-SM or PIM-DM function.

Configuration Steps

▾ Enabling the IPv4 Multicast Routing Function

- Mandatory.
- If there is no special requirement, the IPv4 multicast routing function should be enabled on each router in the local network.

▾ Enabling the PIM-SM or PIM-DM Function

- Mandatory.
- If there is no special requirement, the PIM-SM or PIM-DM function should be directly enabled on an interface of the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to check whether IGMP is enabled on the interface.

Related Commands

▾ Enabling the IPv4 Multicast Routing Function

Command	ip multicast-routing
Parameter	-

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling the PIM-SM or PIM-DM Function

Command	<code>ip pim { sparse-mode dense-mode }</code>
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including routing interfaces, L3AP, SVI and loopback interfaces. All PIM interfaces should be accessible to IPv4 unicast routes.

Configuration Example

▾ Enabling IGMP for a Local Network

Scenario	<ul style="list-style-type: none"> ● Configure an IPv4 unicast routing protocol (such as OSPF) on a router and ensure that the loopback interface is accessible to a unicast route. ● Enable the IPv4 multicast route function on all routers. ● Enable the PIM-SM or PIM-DM function on interfaces interconnecting devices and interfaces connecting user hosts and multicast sources.
	<pre>VSU(config)#ip multicast-routing VSU(config)#int gi 0/5 VSU(config-if-GigabitEthernet 0/5)#ip add 192.168.1.90 255.255.255.0 VSU(config-if-GigabitEthernet 0/5)#ip pim sparse-mode</pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check whether IGMP is enabled on the interface.
	<pre>VSU#show ip igmp interface gigabitEthernet 0/5 Interface GigabitEthernet 0/5 (Index 5) IGMP Active, Querier, Version 2 (default) Internet address is 192.168.1.90 IGMP interface limit is 1024 IGMP interface has 1 group-record states IGMP interface has 0 static-group records</pre>

```
IGMP activity: 3 joins, 0 leaves
IGMP query interval is 125 seconds
IGMP querier timeout is 255 seconds
IGMP max query response time is 10 seconds
Last member query response interval is 10
Last member query count is 2
Group Membership interval is 260 seconds
Robustness Variable is 2
```

Common Errors

- Routers in the network are not enabled with the multicast routing function.
- No multicast interface is available in the network.

3.4.2 Configuring IGMP Routers

Configuration Effect

- Modify the querier timeout and IGMP router parameters will affect the type of packets to be sent and the sending method.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

📄 Specifying the IGMP Version

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

📄 Configuring the Last-Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

📄 Configuring the Last-Member Query Times

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

↘ Configuring the Common Member Query Interval

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

↘ Configuring the Maximum Response Time

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

Run the **show ip igmp interface** *interface-type interface-number* command to display the interface configurations.

Related Commands

↘ Specifying the IGMP Version

Command	ip igmp version { 1 2 3 }
Parameter Description	1: Indicates IGMPv 1. 2: Indicates IGMPv 2. 3: Indicates IGMPv 3.
Command Mode	Interface configuration mode
Usage Guide	After this command is configured, IGMP will automatically restart.

↘ Configuring the Last-Member Query Interval

Command	ip igmp last-member-query-interval <i>interval</i>
Parameter Description	<i>Interval</i> : Indicates the interval for sending the Query packets of a specific group. The value ranges from 1 to 255 in the unit of 0.1s, and the default value is 10 (namely, 1s).
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3. When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

↘ Configuring the Last-Member Query Times

Command	ip igmp last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Indicates the times for sending the Query packets of a specific group, ranging from 2 to 7. The default value is 2.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to IGMPv2 or IGMPv3. When an interface receives a Leave packet, the interface sends Query packets of the group continually and waits for a response from the host. After timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the interface from the IGMP group. The timeout duration is equal to the value of last-member-query-interval multiplied by last-member-query-count plus 1/2 of query-max-response-time .

↘ Configuring the Common Member Query Interval

Command	ip igmp query-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the common member query interval, ranging from 1 to 18,000s. The default value is 125.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the Maximum Response Time

Command	ip igmp query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the maximum response time, ranging from 1 to 25s. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, the interface waits for a response. If timeout occurs, the IGMP router assumes that the group member does not exist in the directly connected network segment and deletes the group information.

↘ Configuring the Querier Timeout

Command	ip igmp query-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keepalive time of the querier, ranging from 60s to 300s. The default value is 255s.
Command Mode	Interface configuration mode
Usage Guide	After sending Query packets, an interface waits for Query packets sent by other devices. If timeout occurs,

	the IGMP router assumes that the querier is unique in the directly connected network segment.
--	---

Configuration Example

📄 Configuring Basic Router Parameters

Scenario	<ul style="list-style-type: none"> ● Configure basic functions of IGMP. ● Specify the IGMPv3. ● Configure the last-member query interval to 15 (1.5s). ● Configure the number of the last-member queries to 3. ● Configure the common member query interval to 130s. ● Configure the maximum response time to 15s. ● Configure the querier timeout to 280s.
	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp version 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-count 3 VSU(config-if-GigabitEthernet 0/5)#ip igmp last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-interval 130 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-max-response-time 15 VSU(config-if-GigabitEthernet 0/5)#ip igmp query-timeout 280</pre>
Verification	Run the show ip igmp interface <i>interface-type interface-number</i> command to check the IGMP functions of the interface.

```
VSU#show ip igmp interface gigabitEthernet 0/5

Interface GigabitEthernet 0/5 (Index 5)
  IGMP Enabled, Active, Querier, Version 3
  Internet address is 192.168.1.90
  IGMP interface limit is 1024
  IGMP interface has 1 group-record states
  IGMP interface has 0 static-group records
  IGMP activity: 3 joins, 0 leaves
  IGMP query interval is 130 seconds
  IGMP querier timeout is 280 seconds
  IGMP max query response time is 15 seconds
  Last member query response interval is 15
  Last member query count is 3
  Group Membership interval is 275 seconds
  Robustness Variable is 2

VSU#
```

Common Errors

- The basic functions of IGMP are not enabled.

3.4.3 Configuring IGMP Group Filtering

Configuration Effect

- A router filters IGMP group members.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

↘ **Configuring the IGMP Group ACL**

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

↘ **Configuring the Maximum Number of IGMP Group Members**

Optional.

If there is no special requirement, you can perform this configuration on all router interfaces directly connected to the local network.

Verification

IGMP Group ACL

- Configure an interface to allow only groups in ACL 1 to join. The access addresses of ACL 1 are 225.0.0.1~225.0.0.255.
- Configure the interface to join a group whose address is 225.0.0.5.
- Configure the interface to join a group whose address is 236.0.0.5.
- View the group information of the current interface.

Maximum Number of IGMP Group Members

- Set the maximum member quantity to 5 on an interface.
- Configure the interface to join a group whose address is from 225.0.0.5 to 225.0.0.10.
- View the group information of the interface.

Related Commands

Configuring the IGMP Group ACL

Command	ip igmp access-group <i>access-list</i>
Parameter Description	<i>access-list</i> : Defines a group address range by using a standard IP ACL or an extended ACL. The value ranges from 1 to 199, 1300 to 2699 and characters.
Command Mode	Interface configuration mode
Usage Guide	Configure this command on an interface to control the groups that hosts in a directly connected network segment can join. Use an ACL to limit the group address range. If Report packets denied by the ACL are received, the packets will be discarded. When IGMPv3 is enabled, this command supports an extended ACL. If the received IGMP Report information is (S1,S2,S3...Sn,G), this command will apply the corresponding ACL to the (0,G) information for matching. Therefore, you must configure a (0,G) record explicitly for the extended ACL in order to normally filter (S1,S2,S3...Sn,G).

Configuring the Maximum Number of IGMP Group Members

Command	ip igmp limit <i>number</i> [except <i>access-list</i>]
Parameter Description	<i>number</i> : Indicates the maximum number of IGMP group members, whose value range varies with devices. The default value is 1,024 for an interface and 65,536 globally. except <i>access-list</i> : Indicates that the groups in the ACL are not counted.

	access-list indicates a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words.
Command Mode	Interface configuration mode
Usage Guide	<p>Global configuration mode: Limits the maximum quantity of the IGMP group members in a system.</p> <p>Interface configuration mode: limits the maximum quantity of IGMP group members on an interface.</p> <p>If the quantity of group members exceeds the interface or global limit, the Report packets received subsequently will be ignored.</p> <p>If an Except ACL is configured, Report packets within a specified range can be normally processed; therefore, the generated group members are not counted.</p> <p>The interface and global configurations can be performed independently. If the global quantity limit is smaller than that for an interface, the global configuration shall be used.</p>

Configuration Example

Configuring IGMP Group Filtering

Scenario	<ul style="list-style-type: none"> Configure the basic functions of IGMP. Configure the access address range of ACL 1 from 225.0.0.1 to 225.0.0.255. Set the address of the group to be joined to 225.0.0.5. Set the address of the group to be joined to 236.0.0.5.
	<pre>VSU(config)#access-list 1 permit 225.0.0.1 225.0.0.255 VSU(config-if-GigabitEthernet 0/5)#ip igmp access-group 1 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 236.0.0.5</pre>
Verification	Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.
	<pre>VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.5 GigabitEthernet 0/5 00:14:00 00:02:45 192.168.1.90</pre>

Configuring the Maximum Number of IGMP Group Members

Scenario	<ul style="list-style-type: none"> Configure the basic functions of IGMP. Configure the maximum number of IGMP group members for the interface to 5. Add group information (225.0.0.5~225.0.0.12). View group information.
	<pre>VSU(config-if-GigabitEthernet 0/5)#ip igmp limit 5</pre>

	<pre> VSU(config-if-GigabitEthernet 0/5)# VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.5 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.6 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.7 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.8 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.9 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.10 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.11 VSU(config-if-GigabitEthernet 0/5)#ip igmp join-group 225.0.0.12 </pre>
Verification	<p>Run the show ip igmp groups [<i>interface-type interface-number</i>] [<i>group-address</i>] [detail] command to display the group information of the interface.</p>
	<pre> VSU(config-if-GigabitEthernet 0/5)#show ip igmp groups IGMP Connected Group Membership Group Address Interface Uptime Expires Last Reporter 225.0.0.5 GigabitEthernet 0/5 00:20:15 00:03:09 192.168.1.90 225.0.0.6 GigabitEthernet 0/5 00:20:24 00:02:58 192.168.1.90 225.0.0.7 GigabitEthernet 0/5 00:00:15 00:04:29 192.168.1.90 225.0.0.8 GigabitEthernet 0/5 00:00:13 00:04:34 192.168.1.90 225.0.0.9 GigabitEthernet 0/5 00:00:11 00:04:33 192.168.1.90 </pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.4 Configuring IGMP Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Configuring the IGMP Proxy Service

- Optional.

- If there is no special requirement, you can perform this configuration on directly connected upstream router interfaces.

↘ Configuring the IGMP Mroute Proxy

- Optional.
- If there is no special requirement, you can perform this configuration on directly connected downstream host interfaces.

Verification

- Set interface 7 for directly connecting to an upstream router as a multicast proxy server.
- Set interface 1 for directly connecting to a downstream host as a multicast proxy.
- Set interface 1 to be joined by groups whose addresses are 225.0.0.6 and 225.5.5.5.
- View the current group information.

Related Commands

↘ Configuring the IGMP Proxy Service

Command	ip igmp proxy-service

Common Errors

- The basic functions of IGMP are not enabled.

3.4.5 Configuring IGMP SSM Mapping

Configuration Effect

- IGMPv3 supports source filtering; however, IGMPv1 and IGMPv2 do not support source filtering, but provides the SSM mapping function to filter sources.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Enabling SSM Mapping

(Mandatory) Enable the SSM mapping function.

Enable the SSM mapping function on a router.

▾ Configuring Static SSM Mapping

Optional.

Configure this function on routers enabled with SSM mapping.

Verification

Run the **show ip igmp ssm-mapping** [*group-address*] command to display SSM mapping information.

Related Commands

▾ Enabling SSM Mapping

Command	ip igmp ssm-map enable
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp ssm-map enable command to enable the SSM mapping function. Run the ip igmp ssm-map static command to set static mapping entries. Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.

▾ Configuring Static SSM Mapping

Command	ip igmp ssm-map static <i>access-list source-address</i>
Parameter Description	<i>access-list</i> : Indicates the group address range set by a standard IP ACL. The value ranges from 1 to 99, 1300 to 1999 and words.

	<i>source-address</i> : Indicates the source address.
Command Mode	Global configuration mode
Usage Guide	<p>Run the ip igmp ssm-map enable command to enable the SSM mapping function.</p> <p>Run the ip igmp ssm-map static command to set static mapping entries.</p> <p>Run IGMPv3 on the interface. When IGMPv1 or IGMPv2 Report packets are received, source addresses of static mappings can be added.</p>

Configuration Example

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Enable SSM mapping. ● Configure static SSM mapping ACL 1.
	<pre>VSU(config)#ip igmp ssm-map enable VSU(config)#ip igmp ssm-map static 1 192.168.5.9</pre>
Verification	Run the show ip igmp ssm-mapping [group-address] command to display SSM mapping information.
	<pre>VSU#show ip igmp ssm-mapping SSM Mapping : Enabled Database : Static mappings configured</pre>

Common Errors

- The basic functions of IGMP are not enabled.

3.4.6 Configuring Alert Option

Configuration Effect

- Check whether IGMP packets contain the Router Alert option and discards the packets without the Router Alert option.
- Support sending IGMP packets with the Router Alert option.

Notes

- The basic functions of IGMP must be configured.

Configuration Steps

▾ Checking Router Alert Option

Optional.

▾ Sending IGMP Packets with Router Alert Option Encapsulated

Optional,

Verification

↘ Checking Router Alert Option

Check whether the IGMP-enabled interface discards the IGMP packets without the Router Alert option.

↘ Sending IGMP Packets with Router Alert Option Encapsulated

Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

Related Commands

↘ Checking Router Alert Option

Command	ip igmp enforce-router-alert
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp enforce-router-alert command to enable Router Alert option check. Run the no ip igmp enforce-router-alert command to disable Router Alert option check.

↘ Sending IGMP Packets with Router Alert Option Encapsulated

Command	ip igmp send-router-alert
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	Run the ip igmp send-router-alert command to enable the function of sending IGMP packets containing Router Alert option. Run the no ip igmp send-router-alert command to disable the function.

Configuration Example

↘ Checking Router Alert Option

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Configure Router Alert option check.
	<pre>VSU(config)#ip igmp enforce-router-alert</pre>

Verification	<p>IGMP packets containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are processed. Run the show ip igmp groups command and you will see 225.1.1.1.</p> <p>IGMP packets not containing Router Alert option 225.1.1.1 are sent to the IGMP-enabled interface and these packets are discarded. Run the show ip igmp groups command and you will not see 225.1.1.1</p>
---------------------	--

📌 Sending IGMP Packets with Router Alert Option Encapsulated

Scenario	<ul style="list-style-type: none"> ● Configure the basic functions of IGMP. ● Configure the function of sending IGMP packets containing router alert option.
	<code>VSU(config)#ip igmp send-router-alert</code>
Verification	Check whether the IGMP-enabled interface sends the IGMP packets containing the Router Alert option.

3.5 Monitoring

Clearing

Description	Command
Clears dynamic group membership from the IGMP buffer.	clear ip igmp group
Clears interface information from the IGMP buffer.	clear ip igmp interface <i>interface-type interface-number</i>

Displaying

Description	Command
Displays all groups in a directly connected subnet.	show ip igmp groups
Displays details about all groups in a directly connected subnet.	show ip igmp groups detail
Displays specified groups in a directly connected subnet.	show ip igmp groups <i>A.B.C.D</i>
Displays details about specified groups in a directly connected subnet.	show ip igmp groups <i>A.B.C.D detail</i>
Displays IGMP configurations of a specified interface in a directly connected subnet.	show ip igmp interface <i>interface-type interface-number</i>

Displays details about all groups of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number detail</i>
Displays information about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number A.B.C.D</i>
Displays details about a specified group of a specified interface in a directly connected subnet.	show ip igmp groups <i>interface-type interface-number A.B.C.D detail</i>
Displays configurations of an IGMP interface.	show ip igmp interface [<i>interface-type interface-number</i>]
Displays configurations of all IGMP interfaces.	show ip igmp interface
Displays configurations of IGMP SSM mapping.	show ip igmp ssm-mapping
Displays the information of IGMP SSM mapping to <i>A.B.C.D</i> .	show ip igmp ssm-mapping <i>A.B.C.D</i>

Debugging

Description	Command
Displays whether IGMP debugging is enabled.	show debugging
Debugs all IGMP information.	debug ip igmp all
Debugs IGMP packet decoding.	debug ip igmp decode
Debugs IGMP packet encoding.	debug ip igmp encode
Debugs IGMP events.	debug ip igmp events
Debugs IGMP FSM.	debug ip igmp fsm
Debugs IGMP state machine.	debug ip igmp tib
Debugs IGMP warning.	debug ip igmp warning

4 Configuring MLD

4.1 Overview

Multicast Listener Discovery (MLD) is a protocol used in the multicast technology.

This protocol receives the multicast member relationship between hosts and routers to determine multicast flow forwarding. Using information obtained from MLD, a device maintains an interface-based multicast listener status table. The multicast listener status table is activated only when at least one host in the link of the interface is a group member.

Currently, MLD has two versions: MLDv1 and MLDv2.

- MLD of both versions supports the Any-Source Multicast (ASM) model.
- MLDv2 can be directly applied to the Source-Specific Multicast (SSM) model.
- MLDv1 can be applied to the SSM model only when MLD SSM mapping is configured.

Protocols and Standards

- RFC2710: Multicast Listener Discovery (MLDv1) for IPv6
- RFC3810: Multicast Listener Discovery Version 2 (MLDv2) for IPv6

4.2 Applications

Application	Description
Configuring the MLD Service on the Local Network	Implements the MLD service on the local network.
Configuring the MLD Proxy Service	In the simple tree topology, the MLD proxy service, instead of the PIM service, is used.

4.2.1 Configuring the MLD Service on the Local Network

Scenario

As shown in Figure 4-1, the local network consists of receiver 1, receiver 2, router A, and router B.

Query messages sent by router A or router B are valid on the local network, and Report messages sent by receiver A and receiver B are also valid on the local network.

Figure 4-1

Remarks	Router C is the egress gateway. Routers A and B are local routers.
----------------	---

Deployment

- Routers A, B, and C run the OSPFv6 protocol.
- Interfaces on routers A, B, and C run the multicast protocol (PIM SMv6 or PIM DMv6).

4.2.2 Configuring the MLD Proxy Service

Scenario

As shown Figure 4-2, the proxy function is enabled on router A. Router A functions as a host and forms a local management group with router B. Router A forwards Report messages from receivers 1 and 2.

Figure 4-2

Remarks	Router A functions as the proxy. Router B provides the PIM service.
----------------	--

Deployment

- Routers A and B run the OSPFv6 protocol.

- Interfaces on routers A and B run the multicast protocol (PIM SMv6 or PIM DMv6).
- The multicast proxy service is enabled on Gi 0/0 and Gi 0/1 of router A.

4.3 Features

Basic Concepts

Host Behaviors and Device Behaviors

Layer-3 multicast devices running multicast management protocols are referred to as devices and their behaviors are device behaviors.

PCs or simulated PCs running multicast management protocols are referred to as hosts and their behaviors are host behaviors.

Querier

Devices interact and compete with each other. After IP address comparison, the device with a lower IP address becomes the querier and periodically sends Query messages.

MLD PROXY-SERVICE Interface

This interface, also called uplink interface, implements host behaviors. It receives Query messages sent by upstream devices and sends Report messages collected by the router proxy.

MLD MROUTE-PROXY Interface

This interface, also called downlink interface, implements router functions. It sends messages received by the proxy service interface and collects and sends host information to the proxy service interface.

MLD SSM-MAP

SSM mapping refers to mapping of source-specific multicast. MLDv1 does not support the SSM model until the SSM-MAP function is enabled.

Overview

Feature	Description
Setting MLD Router Parameters	Sends Query messages to obtain local member information.
Querier Selection Process or Timeout Mechanism	Selects the unique querier in the current network segment.
Filtering MLD Groups	Filters group members and limits the number of group members.
Supporting Static MLD Groups	Stores static group information on the local router instead of obtaining group information by sending Report messages.

Feature	Description
Configuring Simulated Host Group Information	Simulates host behaviors to directly configure group joining information.
Supporting MLD Proxy	Uses this function in the simple tree topology instead of complex multicast routing protocols, such as the PIM.
Supporting SSM-MAP	Provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

4.3.1 Setting MLD Router Parameters

Sends Query messages to obtain local member information.

[Working Principle](#)

A device periodically sends Query messages to ensure that a group has at least one host. If no host is available in a group, the group will be deleted.

[Related Configuration](#)

▾ [Enabling MLD](#)

By default, MLD is disabled on an interface.

Run the **ipv6 pim { sparse-mode | dense-mode }** command to enable or disable MLD on an interface.

MLD can be enabled only after PIM SM or PIM DM is enabled on the interface.

▾ [Configuring MLD Version](#)

By default, the MLD version is 2.

Run the **ipv6 mld version { 1 | 2 }** command to configure or restore the MLD version of an interface.

▾ [Configuring the Query Interval of the Last Member](#)

By default, the interval for sending Query messages is 1s.

Run the **ipv6 mld last-member-query-interval interval** command to configure or restore the interval for sending Query messages.

A larger value means a longer interval for sending Query messages.

▾ [Configuring the Number of Times for Querying the Last Member](#)

By default, the number of times for querying the last member is 2.

Run the **ipv6 mld last-member-query-count count** command to configure or restore the number of times for querying the last member.

A larger value means a larger number of times for querying the last member.

📌 Configuring the Interval for Querying a Common Member

By default, the interval for querying a common member is 125s.

Run the **ipv6 mld query-interval** *seconds* command to configure or restore the interval for querying a common member.

A larger value means a longer interval for querying a common member.

📌 Configuring the Maximum Response Time

By default, the maximum response time is 10s.

Run the **ipv6 mld query-max-response-time** *seconds* command to configure or restore the maximum response time.

A larger value means a longer maximum response time.

4.3.2 Querier Selection Process or Timeout Mechanism

Selects the unique querier in the current network segment. The querier sends a Query message to obtain group information on the local network.

Working Principle

On a multicast network running MLD, a multicast device dedicated to query sends MLD Query messages. The device is determined by election. Initially, all devices are in the querier state. When receiving member relationship Query messages from devices with lower IP addresses, the devices switch from the receiver state to non-querier state. Therefore, there is only one device in the query state in the end. This device has the lowest IP address among all multicast devices on the network. When the querier device does not work, MLD also works. Non-querier devices maintain the keepalive interval timer for other queriers. The timer is reset once the device receives a member relationship query message. If the timer times out, the device starts to send Query messages and a new querier election starts.

Related Configuration

📌 Configuring the Keepalive Interval of the Querier

By default, the keepalive interval of the querier is 255s.

Run the **ipv6 mld querier-timeout** *seconds* command to configure or restore the keepalive interval of the querier.

A larger value means a longer keepalive interval of the querier.

4.3.3 Filtering MLD Groups

Filters group members and limits the number of group members.

Working Principle

If you do not want hosts in the network segment where an interface resides to be added to certain multicast groups, you can configure ACL rules on the interface as a filter. The interface will filter received MLD member relationship Report messages

based on the ACL rules and maintain member relationships only for multicast groups permitted by the rules. The largest number of router members can also be set.

Related Configuration

↳ [Configuring Access Control for Multicast Groups](#)

By default, no access control is configured and hosts can be added to any groups.

Run the **ipv6 mld access-group** *access-list-name* command to configure or restore access control for multicast groups.

After the configuration, the router can receive messages only from hosts in groups specified in the access list.

↳ [Configuring the Maximum Number of MLD Group Members](#)

By default, an MLD group has a maximum of 1024 members.

Run the **ipv6 mld limit** *number* command to configure or restore the maximum number of MLD group members.

A larger value means a larger number of group members.

4.3.4 Supporting Static MLD Groups

Stores static group information on a local router instead of obtaining group information by sending Report messages. The local router can directly exchange group information with the PIM router.

Working Principle

Manually configure static group information.

Related Configuration

↳ [Configuring Static-Group](#)

By default, no static group information is configured.

Run the **ipv6 mld static-group** *group-address* command to configure or cancel static group information.

4.3.5 Configuring Simulated Host Group Information

Simulates host behaviors to directly configure group joining information.

Related Configuration

↳ [Configuring Join-Group](#)

By default, no join-group information is configured.

Run the **ipv6 mld join-group** *group-address* command to configure or cancel join-group information.

4.3.6 Supporting MLD Proxy

In the simply tree topology, it is not necessary to run complex multicast routing protocols (such as PIM). In this case, MLD proxy can be used to send MLD messages for downstream hosts and maintain member relationships.

Working Principle

When an upstream router is configured as an MLD proxy service interface, it functions as a host and can receive Query messages from upstream routers as well as forward group information of downstream hosts. When a downstream router is configured as an MLD multicast proxy interface, it functions as a router and can forward Query messages of upstream routers as well as receive Report messages from downstream routers.

Related Configuration

↘ **Configuring MLD PROXY-SERVICE**

By default, the MLD proxy service is disabled on an interface.

Run the **ipv6 mld proxy-service** command to configure or cancel the MLD proxy function on an interface.

This function must be configured when proxy is used.

↘ **Configuring MLD MROUTE-PROXY**

By default, the multicast proxy service is disabled on an interface.

Run the **ipv6 mld mroute-proxy** interfacename command to configure or cancel the multicast proxy function on an interface.

This function must be configured when proxy is used.

4.3.7 Supporting SSM-MAP

This function provides the SSM model for MLDv1. When a host is added to a group, a specific source can be specified to avoid network bandwidth occupation by unnecessary and invalid multicast data streams. This function is especially useful on a network where multiple multicast sources share the same multicast address.

Working Principle

Based on MLDv1, MLDv2 provides an extra function, that is, source filtering multicast. In MLDv1, a host determines to join a group only based on the group address and receives multicast streams sent to the group address from any source. However, an MLDv2 host advertises the multicast group that the host wants to join and the address of the multicast source that it wants to receive. In MLDv1, source address filtering can be implemented to some extent, but filtering is implemented by enabling SSM-MAP and configuring SSM-MAP static groups on multicast flow receivers.

Related Configuration

↘ **Enabling MLD SSM-MAP**

By default, SSM-MAP is disabled.

Run the **ipv6 mld ssm-map enable** command to enable or disable the SSM-MAP function.

This function must be enabled when SSM-MAP is used.

✚ [Configuring MLD SSM-MAP STATIC](#)

By default, no SSM-MAP static link table is configured.

Run the **ipv6 mld ssm-map static access-list-num A.B.C.D** command to enable or disable the SSM-MAP static link table.

4.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD	 (Mandatory) It is used to configure the multicast service.	
	ipv6 multicast-routing	Enables the IPv6 multicast routing function.
	ipv6 pim sparse-mode	Enables the PIM-SM function.
Configuring MLD Router Parameters	ipv6 mld version { 1 2 }	Configures the MLD version.
	ipv6 mld last-member-query-interval <i>interval</i>	Configures the interval for querying the last member.
	ipv6 mld last-member-query-count <i>count</i>	Configures the number of times for querying the last member.
	ipv6 mld query-interval <i>seconds</i>	Configures the interval for querying a common member.
	ipv6 mld query-max-response-time <i>seconds</i>	Configures the maximum response interval.
Querier Selection Process or Timeout Mechanism	ipv6 mld querier-timeout <i>seconds</i>	Configures the keepalive interval of the querier.
Filtering MLD Groups	ipv6 mld access-group <i>access-list</i>	Filters MLD group members.
MLD Proxy	ipv6 mld proxy-service	Configures the MLD PROXY-SERVICE.
	ipv6 mld mroute-proxy <i>interface-type interface-number</i>	Configures the MLD MROUTE-PROXY.
Supporting SSM-MAP	ipv6 mld ssm-map enable	Enables the SSM-MAP function.
	ipv6 mld ssm-map static <i>access-list</i> <i>source-address</i>	Configures the SSM-MAP static link table.

4.4.1 Configuring Basic Functions of MLD

[Configuration Effect](#)

- Enable the multicast routing function and collect group information on the local network.

Notes

- The PIM SM or PIM DM function must be enabled on an interface.

Configuration Steps

↳ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on all routers on the local network unless otherwise specified.

↳ Enabling the PIM SM or PIM DM Function

- Mandatory.
- The PIM SM or PIM DM function should be directly enabled on an interface on the local network unless otherwise specified.

Verification

Run the **show ipv6 mld interface *interface-type* *interface-number*** command to check whether MLD is enabled on the interface.

Related Commands

↳ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	-

↳ Enabling the PIM SM or PIM DM Function

Command	ipv6 pim { sparse-mode dense-mode }
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be layer-3 interfaces, including: routing, L3AP, SVI, and loopback interfaces. IPv6 unicast routes should be accessible to all PIM interfaces.

Configuration Example

↳ Enabling MLD on the Local Network

Configuration Steps	<ul style="list-style-type: none"> ● Configure an IPv6 unicast routing protocol (such as OSPF) on a router and ensure that unicast routes are accessible to the loopback interface. (Omitted) ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIM SM or PIM DM function on device interconnection interfaces and interfaces for connecting user hosts and multicast sources.
	<pre>VSU(config)#ipv6 multicast-routing VSU(config)#int gi 0/1 VSU(config-if-GigabitEthernet 0/1)# ipv6 address 2001::1/64 VSU(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode</pre>
Verification	Run the show ipv6 mld interface <i>interface-type</i> <i>interface-number</i> command to check whether MLD is enabled on the interface.
	<pre>VSU#show ipv6 mld interface gigabitEthernet 0/1 Interface GigabitEthernet 0/1 (Index 1) MLD Active, Querier, Version 2 (default) Internet address is fe80::2d0:f8ff:fe22:33b1 MLD interface limit is 1024 MLD interface has 0 group-record states MLD interface has 0 join-group records MLD interface has 0 static-group records MLD activity: 0 joins, 0 leaves MLD query interval is 125 seconds MLD querier timeout is 255 seconds MLD max query response time is 10 seconds Last member query response interval is 10 (1/10s) Last member query count is 2 Group Membership interval is 260 Robustness Variable is 2</pre>

Common Errors

- Multicast routing is disabled on routers on the network.
- No multicast interface is available on the network.

4.4.2 Configuring MLD Router Parameters

Configuration Effect

- Modify MLD router parameters to change the message type or sending mode.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

▾ Configuring MLD Version

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Interval for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Number of Times for Querying the Last Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Interval for Querying a Common Member

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

▾ Configuring the Maximum Response Interval

Optional.

This parameter can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

Run the **show ipv6 mld interface *interface-type* *interface-number*** command to view the configuration information.

Related Commands

▾ Configuring the MLD Version

Command	ipv6 mld version { 1 2 }
Parameter	1: Indicates version 1.

Description	2: Indicates version 2.
Command Mode	Interface configuration mode
Usage Guide	After this command is executed, MLD will automatically restart.

↘ Configuring the Interval for Querying the Last Member

Command	ipv6 mld last-member-query-interval <i>interval</i>
Parameter Description	<i>Interval</i> : Specifies the interval for sending Query messages of a specified group. The unit is 0.1s, the value ranges from 1 to 255, and the default value is 10 (1s).
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows: Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2.

↘ Configuring the Number of Times for Querying the Last Member

Command	ipv6 mld last-member-query-count <i>count</i>
Parameter Description	<i>count</i> : Specifies the number of times for sending Query messages of a specified group. The value ranges from 2 to 7. The default value is 2.
Command Mode	Interface configuration mode
Usage Guide	After receiving the Done message, the interface will continuously send Query messages of a specified group and wait for responses from the host. After timeout, it is considered that the no group member exists in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows: Timeout interval = last-member-query-interval x last-member-query-count + query-max-response-time/2

↘ Configuring the Interval for Querying a Common Member

Command	ipv6 mld query-interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Specifies the interval for querying a common member. The unit is s, the value ranges from 1 to 18000, and the default value is 125.
Command Mode	Interface configuration mode
Usage Guide	-

↘ Configuring the Maximum Response Interval

Command	ipv6 mld query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Specifies the maximum response time. The unit is s, the value ranges from 1 to 25, and the default value is 10.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for responses. After timeout, it is considered that no group member exists in the directly-connected network segment and group information is deleted.

Configuration Example

▾ Configuring Basic Router Parameters

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of MLD. (Omitted) ● Configure MLD version 2. ● Configure the interval for querying the last member as 15 (1.5s). ● Configure the number of times for querying the last member as 3. ● Configure the interval for querying the common member as 130s. ● Configure the maximum response time as 15s.
	<pre> VSU(config-if-GigabitEthernet 0/1)#ipv6 mld version 2 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-count 3 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld last-member-query-interval 15 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-interval 130 VSU(config-if-GigabitEthernet 0/1)#ipv6 mld query-max-response-time 15 </pre>
Verification	Run the show ipv6 mld interface <i>interface-type</i> <i>interface-number</i> command to check whether MLD is enabled on the interface.

```
VSU(config-if-GigabitEthernet 0/1)# show ipv6 mld interface gi 0/1

Interface GigabitEthernet 0/1 (Index 1)

MLD Enabled, Active, Querier, Version 2 (default)

Internet address is fe80::2d0:f8ff:fe22:33b1

MLD interface limit is 1024

MLD interface has 0 group-record states

MLD interface has 0 join-group records

MLD interface has 0 static-group records

MLD activity: 0 joins, 0 leaves

MLD query interval is 130 seconds

MLD querier timeout is 267 seconds

MLD max query response time is 15 seconds

Last member query response interval is 15 (1/10s)

Last member query count is 3

Group Membership interval is 275

Robustness Variable is 2
```

Common Errors

- Basic functions of MLD are not enabled.

4.4.3 Querier Selection Process or Timeout Mechanism

Configuration Effect

- Select the unique querier on the local network.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

- This function must be configured if the querier keepalive interval needs to be configured.
- This function can be configured on all MLD-enabled interfaces on the local network.

Verification

Run the **show ipv6 mld interface *interface-type* *interface-number*** command to view the configuration information of the interface.

Related Commands

Configuring the Keepalive Interval of Other Queriers

Command	<code>ipv6 mld querier-timeout seconds</code>
Parameter Description	<i>seconds</i> : Specifies the keepalive interval for other queriers. The unit is s, the value ranges from 60 to 300, and the default value is 255.
Command Mode	Interface configuration mode
Usage Guide	After sending Query messages, the interface waits for Query messages from other devices. After timeout, it is considered that it is the unique querier in the directly-connected network segment.

Configuration Example

Configuring the Keepalive Interval of Other Queriers

Configuration Steps	<ul style="list-style-type: none"> Configure the basic functions of MLD. (Omitted) Configure the keepalive interval of a querier as 280s.
	<pre>VSU(config-if-GigabitEthernet 0/1)#ipv6 mld querier-timeout 280</pre>
Verification	Run the <code>show ipv6 mld [vrf vrf-name] interface <i>interface-type</i> interface-number</code> command to check whether MLD is enabled on the interface.

```
VSU#show ipv6 mld interface gigabitEthernet 0/1

Interface GigabitEthernet 0/1 (Index 1)

  MLD Enabled, Active, Querier, Version 2 (default)

  Internet address is fe80::2d0:f8ff:fe22:33b1

  MLD interface limit is 1024

  MLD interface has 0 group-record states

  MLD interface has 0 join-group records

  MLD interface has 0 static-group records

  MLD activity: 0 joins, 0 leaves

  MLD query interval is 130 seconds

  MLD querier timeout is 280 seconds

  MLD max query response time is 15 seconds

  Last member query response interval is 15 (1/10s)

  Last member query count is 3

  Group Membership interval is 275

  Robustness Variable is 2
```

Common Errors

- The basic functions of MLD are not enabled.

4.4.4 Filtering MLD Groups

Configuration Effect

- A router filters MLD group information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

↘ Configuring Access Control for Multicast Groups

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

↘ Configuring the Maximum Number of MLD Group Members

Optional.

This function can be configured on all router interfaces directly connected to the local network unless otherwise specified.

Verification

Filtering MLD Groups

Configure the interface to allow for only groups in link table 1. The access address of link table 1 is (FF66::100/64).

Configure the interface to add a group FF66::05.

Configure the interface to add a group FF65::05.

Check group information on the interface.

Configuring the Maximum Number of MLD Group Members

Configure the number of group members as 5 on the interface.

Configure the interface to add a group (FF66::05 ~ FF65::0B).

Check group information on the interface.

Related Commands

Configuring Access Control for Multicast Groups

Command	<code>ipv6 mld access-group access-list</code>
Parameter Description	access-list: Specifies the group address range by using IP standard ACLs or IP extended ACLs. The value ranges from 1 to 199, 1300 to 2699, and WORD.
Command Mode	Interface configuration mode
Usage Guide	<p>After running this command on the interface, you can control the groups that hosts in the directly-connected network segment can join. Use ACLs to limit the group address range. Report messages denied by the ACLs will be discarded.</p> <p>When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 messages. When the received MLD Report message is (S1,S2,S3...Sn,G), this command will match (0,G) using the corresponding ACLs. Therefore, to normally use this command, you must explicitly configure a (0, G) in the extended ACLs to filter (S1,S2,S3...Sn,G).</p>

Configuring the Maximum Number of MLD Group Members

Command	<code>ipv6 mld limit number [except access-list]</code>
Parameter Description	<p><i>number</i>: Specifies the maximum number of MLD group members. The value range depends on the specific device. The interface default value is 1024 and the global one is 65536.</p> <p>except access-list: Groups in the access list are not counted.</p> <p>The access list is an IP standard ACL. The value ranges from 1 to 99, 1300 to 1999, and WORD.</p>
Command Mode	Interface configuration mode

Usage Guide	<p>Global configuration mode: Limits the number of MLD group members on the whole device.</p> <p>Interface configuration mode: Limits the number of MLD group members of the interface.</p> <p>If the number of group members exceeds the interface limit or global limit, subsequent Report messages will be ignored.</p> <p>If an except list is configured, Report messages in a specified range can be normally processed. Therefore, the group members are not counted.</p> <p>Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, use the global limit.</p>
--------------------	--

Configuration Example

Configuring Group Filtering

Configuration Steps	<ul style="list-style-type: none"> Configure the basic functions of MLD. (Omitted) Configure the access address of link table 1 as (FF66::100/64). Configure the group to join as FF66::05. Configure the group to join as FF65::05.

Common Errors

- The basic functions of MLD are not enabled.

4.4.5 MLD Proxy

Configuration Effect

- Configure the router proxy function and collect local member information.

Notes

- The basic functions of MLD must be configured.

Configuration Steps

▾ Configuring MLD PROXY-SERVICE

Optional.

This function can be configured on the interface of routers directly connected to the upstream devices unless otherwise specified.

▾ Configuring MLD MROUTE-PROXY

Optional

This function can be configured on the interface of hosts directly connected to the downstream devices unless otherwise specified.

Verification

- Configure the interface that directly connects interface 7 and upstream router as the multicast proxy service.
- Configure the interface that directly connects interface 1 and downstream host as the multicast proxy.
- Configure groups FF66::05 and FF66::06 to be added to interface 1.
- Check information of the current group.

5 Configuring PIM-DM

5.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC3973: Protocol Independent Multicast - Dense Mode (PIM-DM)
- RFC2715: Interoperability Rules for Multicast Routing Protocols

5.2 Applications

Application	Description
Providing the Multicast Service in the Same Network	The multicast service is provided in the same network.
PIM-DM Application in a Hot Backup Environment	The multicast PIM-DM protocol runs in a hot backup environment.

5.2.1 Providing the Multicast Service in the Same Network

Scenario

The multicast service is provided in the same network.

The following figure is taken as an example:

- A multicast source sends a multicast packet, and Receiver A and Receiver B in the same network receive the multicast packet.

Figure 5-1

Remarks	<p>A, B, and C are Layer-3 routers.</p> <p>The multicast source is connected to the Gi0/1 interface of A, Receiver A is connected to the Gi0/1 interface of B, and Receiver B is connected to Gi0/1 of C.</p>
----------------	---

Deployment

- Run the Open Shortest Path First (OSPF) protocol in the same network to implement unicast routing.
- Run the PIM-DM protocol in the same network to implement multicast routing.
- Run the Internet Group Management Protocol (IGMP) in a user host network segment to implement group member management.

5.2.2 PIM-DM Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-DM. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 5-2

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.
----------------	--

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-DM on R1 and R2 to implement multicast routing.
- Make R2 run in a hot backup environment.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.
----------------	---

5.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM Routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called Upstream Interfaces, and the PIM interfaces where multicast packets are sent are called Downstream Interfaces.

The network segments where upstream interfaces are located are called Upstream Network Segments. The network segments where downstream interfaces are located are called Downstream Network Segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders are able to reject specified multicast packets or limit the transmission of PIM messages.

↘ Multicast Distribution Tree

Multicast packets are packets transmitted from one point to multiple points. The forwarding path is in a tree structure. This forwarding path is called the Multicast Distribution Tree (MDT).

↘ (*,G), (S,G)

- (*,G): Packets sent from any source to Group G, the corresponding routing entries, and the forwarding path called Rendezvous Point Tree (RPT).
- (S,G): Packets sent from Source S to Group G, the corresponding routing entries, and the forwarding path called Shortest Path Tree (SPT).

Overview

Feature	Description
PIM-DM Neighbor	Neighbor relationships are established between PIM routers to form a PIM network.
PIM-DM SRM	PIM-DM uses a State Refresh Message (SRM) to update the network state.

5.3.1 PIM-DM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control messages can be exchanged or multicast packets can be forwarded.

Working Principle

A Hello message is sent from a PIM interface. For the IPv4 multicast packet with the Hello message encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet with the Hello message encapsulated, the destination address is ff02::d.

Function of a Hello message: It is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13 or ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a Triggered-Hello-Delay message is used to generate a random time. Within the time, the interface sends Hello packets.

Coordinating Protocol Parameters

A Hello message includes multiple protocol parameters, which are described as follows:

- DR_Priority: Router interfaces contend for the designated router (DR) based on their DR priorities. A higher priority means a higher chance of winning.
- Holdtime: Time in which a neighbor is held in the reachable state
- LAN_Delay: LAN delay for transmitting a Prune message in a shared network segment
- Override-Interval: Prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override message to the upstream interface within the Override-Interval.

$\text{LAN_Delay} + \text{Override-Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune message from a downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection message from the downstream interface, the PIM router cancels pruning.

Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

Enabling PIM-DM on an Interface

By default, PIM-DM is disabled on an interface.

Use the **ip pim dense-mode** command to enable or disable PIM-DM on an interface.

PIM-DM must be enabled on an interface to involve the interface in the PIM protocol.

📌 [Setting the Interval of Hello Messages on an Interface](#)

By default, a Hello message is sent at an interval of 30 seconds.

The **ip pim query-interval** *interval-seconds* command is used to adjust the interval of Hello messages. The value of the interval ranges from 1 to 65,535.

A Hello message is transmitted less frequently when the value of *interval-seconds* is larger.

5.3.2 PIM-DM MDT

The three basic mechanisms dense-mode PIM uses to build multicast forwarding trees are: flood, prune, and graft.

[Working Principle](#)

When a multicast source sends multicast packets, the system forwards them to the outgoing interfaces of multicast neighbors and local members. The Reverse Path Forwarding (RPF) check needs to be conducted on all packets received through the upstream interface of the device. Packets that fail the RPF check will be discarded. Multicast packets that pass the RPF check are further forwarded if there is an outgoing interface. If no outgoing interface is available, the device sends a prune packet to the upstream interface. After receiving the prune packet, the upstream interface identifies the source interface of the prune packet as the Pruned state and sets the Pruned Timer (PI). In this way, a multicast forwarding tree with the multicast source as the root is created.

When the system receives a Join message from a local member, if a downstream device in the Pruned state sends a Graft message to the upstream device, the upstream device returns a Graft-Ack message and resumes forwarding of multicast data to the interface of the downstream device after receiving the Graft message.

-
- 📘 In environment deployment, when multiple PIM-DM neighbors are created through multiple links between devices and downstream devices need to receive no or few packets, the CPU usage may be high. In this scenario, PIM-SM is recommended for the environment deployment
-

[Related Configuration](#)

📌 [Configuring the Prune Override Interval on an Interface](#)

By default, the prune override interval is 500 ms.

Run the **ip pim override-interval** *interval-milliseconds* command to change the prune override interval.

5.3.3 PIM-DM SRM

PIM-DM uses an SRM to refresh the network state.

Working Principle

Devices connected to a multicast source periodically send SRMs to downstream devices to notify changes of the network topology. After receiving the SRMs, the adjacent devices receiving the SRMs add the local topology state information to the messages by modifying some fields in SRMs, and send the messages to downstream devices. When the messages reach leaf devices, the state information of the entire network is updated.

Related Configuration

Disabling the Processing and Forwarding of SRMs

By default, the processing and forwarding of SRMs are enabled.

The **ip pim state-refresh disable** command is used to disable the processing and forwarding of SRMs.

- Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable SRM in general conditions.

Setting the Interval of SRMs

By default, an SRM is sent at an interval of 60 seconds.

The **ip pim state-refresh origination-interval *interval-seconds*** command is used to adjust the interval of SRMs. The value of the interval ranges from 1 to 100.

SRMs are transmitted less frequently when the value of *interval-seconds* is larger.

- Only devices that are directly connected to a multicast source will periodically send a PIM SRM to downstream interfaces. For a device not directly connected to the multicast source, the interval of SRMs on its downstream interfaces is invalid.

5.3.4 MIB

Connected to other agents, the Simple Network Management Protocol (SNMP) manager uses information in the Management Information Base (MIB) to directly manage the PIM-DM function.

Working Principle

The MIB specifies variables (namely information that can be queried and set by the management process) maintained by network elements and directly manages the PIM-DM function.

Related Configuration

Enabling PIM-DM MIB

By default, the PIM-DM MIB function is enabled.

The **ip pim mib dense-mode** command is used to enable the PIM-DM MIB function.

5.4 Configuration

Configuration	Description and Command	
Configuring PIM-DM Basic Functions	 (Mandatory) It is used to create the multicast service.	
	ip multicast-routing	Enables IPv4 multicast routing.
	ip pim dense-mode	Enables PIM-DM.
Configuring PIM-DM Neighbors	 (Optional) It is used to limit the (S,G) pairs of legitimate multicast packets in Any Source Multicast (ASM) model.	
	ip pim query-interval <i>interval-seconds</i>	Sets the Interval of Hello messages on an interface.
	ip pim propagation-delay <i>interval-milliseconds</i>	Sets the prune propagation delay on an interface.
	ip pim override-interval <i>interval-milliseconds</i>	Sets the prune override interval on an Interface.
	ip pim neighbor-filter <i>access-list</i>	Configures neighbor filtering on an interface.
Configuring PIM-DM SRMs	ip pim state-refresh disable	Disables the processing and forwarding of SRMs.
	ip pim state-refresh origination-interval <i>interval-seconds</i>	Sets the Interval of SRMs on an interface.
Configuring PIM-DM MIB	ip pim mib dense-mode	Enables PIM-DM MIB.

5.4.1 Configuring PIM-DM Basic Functions

Configuration Effect

- Create a PIM-DM network and provide data sources and user terminals in the network with the IPv4 multicast service.

Notes

- PIM-DM needs to use the unicast routes existing in the network. Therefore, IPv4 unicast routing must be configured in the network.

Configuration Steps

↘ Enabling IPv4 Multicast Routing

- Mandatory
- IPv4 multicast routing should be enabled on each router unless otherwise specified.

↘ Enabling PIM-DM

- Mandatory
- PIM-DM should be enabled on the following interfaces unless otherwise specified: interconnected interfaces on routers and interfaces connecting multicast sources and user hosts.

Verification

Make multicast sources send multicast packets and make user hosts join the groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether correct PIM-DM routing entries are created on routers.

Related Commands

↳ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling PIM-DM

Command	ip pim dense-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces. For all PIM interfaces, IPv4 unicast routes should be reachable.

↳ Displaying the PIM-DM Routing Table

Command	show ip pim dense-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [summary]
Parameter Description	<i>group-or-source-address</i> : Indicates a group address or source address. <i>group-or-source-address</i> : Indicates a group address or source address (The two addresses cannot be group addresses or source addresses at the same time). summary : Displays the routing table summary.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Check whether sufficient routing entries are provided.

Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.

Configuration Example

▾ Enabling IPv4 Multicast Routing on the IPv4 Network

<p>Scenario Figure 5-3</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure IPv4 unicast routing protocols (for example, OSPF) on all the routers. ● Enable the IPv4 multicast routing function on all the routers. ● Enable the PIM-DM function on all the interconnected interfaces of the routers, Source, and Receiver..
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim dense-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim dense-mode A(config-if)# exit</pre>
<p>B</p>	<pre>B# configure terminal B(config)# ip multicast-routing B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim dense-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim dense-mode B(config-if)# exit</pre>
<p>Verification</p>	<p>Configure the multicast source (192.168.1.10) to send packets to G (229.1.1.1). Make Receiver A join G.</p> <ul style="list-style-type: none"> ● Check whether the multicast packets from Source G are received by Receiver A..

<ul style="list-style-type: none"> ● Check PIM-DM routing tables on Router A and Router B. 	
A	<pre> A# show ip pim dense-mode mroute PIM-DM Multicast Routing Table (192.168.1.10, 229.1.1.1) MRT lifetime expires in 182 seconds Source directly connected on GigabitEthernet 0/1 State-Refresh Originator State: Originator SRT:57, SAT:147 Upstream IF: GigabitEthernet 0/1 Upstream State: Forwarding Assert State: NoInfo Downstream IF List: GigabitEthernet 0/2, in 'olist': Downstream State: NoInfo Assert State: NoInfo </pre>
B	<pre> B# show ip pim dense-mode mroute PIM-DM Multicast Routing Table (192.168.1.10, 229.1.1.1) MRT lifetime expires in 130 seconds RPF Neighbor: 192.168.2.1, Nexthop: 192.168.2.1, GigabitEthernet 0/2 Upstream IF: GigabitEthernet 0/2 Upstream State: Forwarding Assert State: Loser, AT:125 Downstream IF List: GigabitEthernet 0/1, in 'olist': Downstream State: NoInfo Assert State: NoInfo </pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.2 Configuring PIM-DM Neighbors

Configuration Effect

- Coordinate protocol parameters and adjust parameters in the Hello packet.
- Enable neighbor filtering to improve network security.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- Set parameters on PIM router interfaces unless otherwise specified.

Verification

- Set parameters in a Hello packet on an interface and run the **debug ip pim dense-mode encode** command to check parameters.
- Enable neighbor filtering and run the **show ip pim dense-mode decode** command to display neighbor filtering information.
- Run the **show running-config interface** [*interface-type interface-number*] command to display configurations on an interface.

Related Commands

▾ Setting the Interval of Hello Messages

Command	ip pim query-interval <i>interval-seconds</i>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 65,535 in the unit of seconds.
Command Mode	Interface configuration mode
Usage Guide	When the Hello interval is set, the holdtime value will be updated as its 3.5 times.
<p>i Every time when the interval of Hello messages is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval of Hello messages multiplied by 3.5 is greater than 65,535, the holdtime value is updated as 65,535.</p>	

▾ Setting the Prune Propagation Delay

Command	ip pim propagation-delay <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command	Interface configuration mode

Mode	
Usage Guide	Set propagation-delay of an interface, that is, configure the prune propagation delay of an interface.

▾ Setting the Prune Override Interval

Command	ip pim override-interval <i>interval-milliseconds</i>
Parameter Description	<i>interval-milliseconds</i> : The value ranges from 1 to 32,767 in the unit of milliseconds.
Command Mode	Interface configuration mode
Usage Guide	Set override-interval of an interface, that is, configure the prune override time of an interface.

▾ Configuring PIM-DM Neighbor Filtering

Command	ip pim neighbor-filter <i>access-list</i>
Parameter Description	<i>access-list</i> : The supported ACL ranges from 1 to 99. Naming an ACL is also supported.
Command Mode	Interface configuration mode
Usage Guide	<p>Only addresses that meet ACL filtering conditions can be used as PIM neighbors of the current interface. Otherwise, the addresses filtered out cannot be neighbors.</p> <p>Peering refers to exchange of protocol packets between PIM neighbors. If peering with a PIM device is suspended, the neighbor relationship with it cannot be formed so that PIM protocol packets will not be received from the device.</p>

Configuration Example

▾ Configuring PIM-DM Neighbors on the IPv4 Network

Scenario Figure 5-4	 <p>The diagram shows two routers, labeled A and B, connected by a line representing a network link. Both routers have a circular icon with four arrows pointing outwards, indicating they are multi-directional devices. The connection points are labeled 'Gi0/1' on both sides.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-DM (omitted). ● Set protocol parameters in a Hello packet on the Gi0/1 interface of device A.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim query-interval 60</pre>

	<pre>A(config-if)# ip pim propagation-delay 800 A(config-if)# ip pim override-interval 1000 A(config-if)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show running-config interface [<i>interface-type interface-number</i>] command to display configurations on an interface. ● Run the debug ip pim dense-mode encode command to debug parameters in a Hello packet.
A	<pre>A# (config)#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 245 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim query-interval 60 ip pim propagation-delay 800 ip pim override-interval 1000</pre>
	<pre>A# debug ip pim dense-mode encode *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello Hold-Time 210 *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello Gen-ID 1362200073 *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello PD=800 ms, OI=1000 ms *Dec 22 15:00:58: %7: [ENCODE] Enc Hello: Hello SR-Interval 60 *Dec 22 15:00:58: %7: [ENCODE] Enc Msg Hdr: Hello Checksum=65396, MsgLen=34 Assert State: Loser, AT:125</pre>

➤ **Configuring PIM-DM Neighbor Filtering on the IPv4 Network**

Scenario Figure 5-5	
Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-DM (omitted). ● Configure an ACL on device A.

	<ul style="list-style-type: none"> ● Configure PIM neighbor filtering on the Gi0/1 interface of device A.
A	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim query-interval 60 A(config-if)# ip pim propagation-delay 800 A(config-if)# ip pim override-interval 1000 A(config-if)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show running-config interface [interface-type interface-number] command to display configurations on the interface. ● Run the debug ip pim dense-mode decode command to debug parameters in a Hello packet.
A	<pre>A#show running-config interface gigabitEthernet 0/2 Building configuration... Current configuration : 187 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim neighbor-filter pim-dm</pre>
	<pre>A# debug ip pim dense-mode decode Dec 22 15:15:47: %7: [DECODE] Dec Msg: PIM Hello message, version 2 Dec 22 15:09:47: %7: [DECODE] Dec Msg: Neighbor 192.168.2.2/32 on GigabitEthernet 0/1 denied by access-list pim-dm</pre>

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.3 Configuring PIM-DM SRMs

Configuration Effect

- Enable or disable the PIM-DM SRM function.
- Adjust the interval of SRMs.

Notes

- Basic functions of PIM-DM must be configured.

Configuration Steps

- The interval of SRMs is only applicable only to the PIM router interfaces that are directly connected to the multicast source.

Verification

- Configure the PIM-DM SRMs and run the **show running-config** command to display the SRM status.
- Run the **show ip pim dense-mode track** command to display the SRM number.
- Run the **show running-config interface** [*interface-type interface-number*] command to display interface configurations.

Related Commands

▾ Disabling the Processing and Forwarding of SRMs

Command	ip pim state-refresh disable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the processing and forwarding of SRMs are disabled, the State Refresh Capable option is not included in a Hello packet, and is not processed when the Hello packet is received. Disabling the SRM function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, it is recommended not to disable this function in general conditions.

▾ Setting the Interval of SRMs

Command	ip pim state-refresh origination-interval <i>interval-seconds</i>
Parameter Description	<i>interval-seconds</i> : The value ranges from 1 to 100 in the unit of second.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

▾ Disabling the Processing and Forwarding of SRMs on an Interface on the IPv4 Network

<p>Scenario Figure 5-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-DM (omitted). ● Disable processing and forwarding of a PIM-DM SRM on an Interface of device A.
<p>A</p>	<pre>A# configure terminal A(config)# ip pim state-refresh disable</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show running-config command to check the configuration.
<p>A</p>	<pre>A# (config)# show running-config ... ! ip pim state-refresh disable ! ...</pre>

📌 **Setting the Interval of SRMs on the IPv4 Network**

<p>Scenario Figure 5-7</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-DM (omitted). ● Set the interval of PIM-DM SRMs on the Gi0/1 interface of device A.

<p>A</p>	<pre>A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim state-refresh origination-interval 5 A(config-if)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show running-config interface [<i>interface-type interface-number</i>] command to display interface configurations. ● Run the show ip pim dense-mode track command to display the SRM number.
<p>A</p>	<pre>A#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 201 bytes ! interface GigabitEthernet 0/1 ip pim dense-mode ip pim state-refresh origination-interval 5</pre>
	<pre>A #show ip pim dense-mode track PIM packet counters Elapsed time since counters cleared: 00:18:54 received sent Valid PIMDM packets: 38 102 Hello: 38 76 Join/Prune: 0 0 Graft: 0 0 Graft-Ack: 0 0 Assert: 0 0 State-Refresh: 0 26 PIM-SM-Register: 0 PIM-SM-Register-Stop: 0 PIM-SM-BSM: 0 PIM-SM-C-RP-ADV: 0</pre>

Unknown Type:	0
Errors:	
Malformed packets:	0
Bad checksums:	0
Unknown PIM version:	0
Send errors:	0

Common Errors

- IPv4 unicast routing is incorrectly configured.
- IPv4 multicast routing is not enabled on a certain router.
- PIM-DM is not enabled on a certain interface.

5.4.4 Configuring PIM-DM MIB

Configuration Effect

- Enable the MIB function for PIM-DM.

Verification

- Configure the MIB function of PIM-SM and run the **show running-config** command to check whether the function is configured.

Related Commands

↳ Enabling PIM-DM MIB

Command	ip pim mib dense-mode
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

5.5 Monitoring

Clearing

Description	Command
-------------	---------

Resets the statistic start time and clears the counters of PIM-DM packets.	clear ip pim dense-mode track
--	--------------------------------------

Displaying

Description	Command
Displays the help information of the commands with IP PIM as the key word.	ip pim help
Displays PIM-DM information of an interface.	show ip pim dense-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the PIM-DM neighbors.	show ip pim dense-mode neighbor [<i>interface-type interface-number</i>]
Displays the PIM-DM next-hop information .	show ip pim dense-mode nexthop
Displays the PIM-DM routing table.	show ip pim dense-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [summary]
Displays the number of PIM-DM packets sent and received since the statistic start time.	show ip pim dense-mode track

6 Configuring PIM-SM

6.1 Overview

Protocol Independent Multicast (PIM) is an intra-domain multicast routing protocol.

A multicast source sends a packet to a group address. The packet is forwarded by network devices hop by hop and finally reaches the group members. On Layer-3 network devices, PIM is used to create and maintain multicast routing entries, so as to support multicast forwarding.

PIM works in two modes: Protocol Independent Multicast - Sparse Mode (PIM-SM) and Protocol Independent Multicast - Dense Mode (PIM-DM).

- PIM-SM is applicable to large-scale networks where group members are sparsely distributed in a wide scope.
- PIM-DM is applicable to small networks where group members are densely distributed.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

6.2 Applications

Application	Description
Enabling ASM for PIM-SM	The receiver receives any multicast source.
Enabling SSM for PIM-SM	The receiver receives only a specific multicast source.

6.2.1 Enabling ASM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives any multicast source.

Figure 6-1

Remarks	R 1 is connected directly to the multicast source. R 2 serves as the rendezvous point (RP). R 3 is connected directly to Receiver A. R 4 is connected directly to Receiver B.
----------------	--

Deployment

- Run the Open Shortest Path First (OSPF) protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the Internet Group Management Protocol (IGMP) in the network segment of the user host to manage group members.

6.2.2 Enabling SSM for PIM-SM

Scenario

Provide multicast services within only one domain.

For example, in the following figure, the receiver receives a specific multicast source.

Figure 6-2

Remarks	R 1 is connected directly to the multicast source. R 2 serves as the RP.
----------------	---

R 2 is connected directly to Receiver A. R 2 is connected directly to Receiver B.
--

Deployment

- Run the OSPF protocol to realize unicast routing.
- Run PIM-SM to realize multicast routing.
- Run the source-specific multicast (SSM) of PIM-SM within the domain.
- Run IGMPv3 in the network segment of the user host to manage group members.

6.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

A router running PIM is called a PIM router. An interfaces running PIM is called a PIM interface.

Multicast packets are forwarded on PIM routers. The PIM interfaces where multicast packets are received are called upstream interfaces, and the PIM interfaces where multicast packets are sent are called downstream interfaces.

The network segments where upstream interfaces are located are called upstream network segments, and the network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces to form a PIM network.

On some PIM interfaces, borders can be set to divide a large PIM network into multiple PIM domains. The borders can reject the passage of specific multicast packets or limit the transmission of PIM packets.

↘ Multicast Distribution Tree, DR, and RP

Multicast packets are transmitted from one point to multiple points, forming a tree-shaped forwarding path. Such forwarding path is called the multicast distribution tree (MDT), which includes the following two types:

- RP Tree (RPT): It is rooted at an RP, and uses the designated router (DR) of the member groups connected to it as its leaves.
- Shortest path tree (SPT): It is rooted at a DR that is connected to the multicast source, and uses the RP or the DR of the member groups connected to it as its leaves.

Both the DR and RP are the functions of a PIM router.

- An RP collects the information of a multicast source or multicast member on the network.
- The DR connected to the multicast source advertises the multicast source information to the RP; the DR connected to multicast group members advertises the information of multicast group members to the RP.

↘ (*, G), (S, G)

- (*, G): Indicates the packets sent from any source to a group (G), the corresponding route entries, and the RPT.
- (S, G): Indicates the packets sent from the source (S) to a group (G), the corresponding routing entries, and the SPT.

📌 ASM, SSM

PIM-SM supports both any-source multicast (ASM) and SSM, and it is applicable to different multicast group address segments.

- ASM: In this model, a user is not allowed to select a multicast source. The user host joins a group, and receives the packets sent from all sources.
- SSM: In this model, a user can select a multicast source. The user host joins a group and specifies the source address. Then only the packets sent from this source address is received.

i Requirements for using an SSM model: Before selecting a multicast source, you need to learn the address of the multicast source using other network services.

Overview

Feature	Description
PIM-SM Neighbor	Establishes neighbor relationships between RIM routers to form a PIM network.
DR Election	In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members. In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.
BSR Mechanism	On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses.
RP Mechanism	On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router.
Register Information of the Multicast Source	When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.
Creating an RPT	When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.
Creating an SPT	When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT.
ASM and SSM	A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model.

6.3.1 PIM-SM Neighbor

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before PIM control packets can be exchanged or multicast packets can be forwarded.

Working Principle

A PIM interface sends a Hello packet. For the IPv4 multicast packet whose Hello packet is encapsulated, the destination address is 224.0.0.13 (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the Time To Live (TTL) value is 1. For the IPv6 multicast packet whose Hello packet is encapsulated, the destination address is ff02::d.

A Hello packet is used to discover neighbors, coordinate protocol parameters, and maintain neighbor relationships.

↘ Discovering Neighbors

PIM routers in the same network segment receive multicast packets from the destination address 224.0.0.13. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

↘ Coordinating Protocol Parameters

A Hello packet includes multiple protocol parameters, which are described as follows:

- DR_Priority: indicates the priority of a router interface for competing for the DR. A higher priority means a higher chance of winning.
- Holdtime: Indicates the time in which a neighbor is held in the reachable state
- LAN_Delay: Indicates the LAN delay for transmitting a Prune packet in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello packet.

When a PIM router receives a Prune packet from an upstream interface, it indicates that downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, the PIM router must send a Prune Override packet to the upstream interface within the override interval.

$\text{LAN_Delay} + \text{Override Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune packet from a downstream interface, the PIM router will not immediately perform pruning until PPT times out. Within the time of PPT, if the PIM router receives a Prune rejection packet from the downstream interface, the PIM router cancels pruning.

↘ Maintaining Neighbor Relationships

A Hello packet is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any change of PIM neighbors will cause change of the multicast topology in the network. If an upstream or downstream neighbor in an MDT is unreachable, multicast routes converge again and the MDT is reshaped.

Related Configuration

↳ Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, candidate RP (C-RP), or candidate BSR (C-BSR), corresponding roles of the PIM protocol cannot be run.

↳ Setting the Interval of Hello Packets on an Interface

By default, a Hello packet is sent every 30s.

Run **ip pim query-interval** *interval-seconds* to adjust the interval of Hello packets. The value ranges from 1 to 65,535.

A Hello packet is transmitted less frequently when the value of *interval-seconds* is greater.

6.3.2 DR Election

In the network segment where group member hosts are located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the group members.

In the network segment where the multicast source is located, PIM neighbors compete for the DR, and the one wins the election becomes the DR for connecting to the multicast source.

The DR sends Join/Prune packets toward the MDT, or sends the multicast source data to the MDT.

Working Principle

When creating a PIM neighbor, you can send a Hello packet to obtain the IP address and DR priority of the neighbor to elect a DR.

Two parameters play a key role in winning the DR election: the DR priority of an interface and the IP address of the interface.

↳ DR Priority of an Interface

During the DR election, the RIM router with the highest DR priority will be elected as the DR.

↳ Interface IP Address

During the DR election, if the priority of interfaces is the same, then interface IP addresses will be compared. The interface with the maximum IP address will be elected as the DR.

Related Configuration

↳ Enabling PIM-SM on an Interface

By default, PIM-SM is disabled on an interface.

Run **ip pim sparse-mode** to enable or disable PIM-SM on an interface.

PIM-SM must be enabled on an interface to involve the interface in the PIM protocol. If PIM-SM is not enabled for the interface of a DR, static RP, C-RP, or C-BSR, corresponding protocols cannot be run.

↘ Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run **ip pim dr-priority** *priority-value* to adjust the DR priority of the interface. The value ranges from 0 to 4,294,967,294.

The DR priority is used in the DR election in the network segment directly connected the interface. A greater value indicates a higher priority.

6.3.3 BSR Mechanism

On a PIM network, the BSR generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain. All the routers on the entire network will receive these bootstrap packets, and record these candidate RPs and their corresponding group addresses.

Working Principle

One or multiple candidate BSRs are configured in a PIM-SM domain. You need to apply a certain algorithm to select the BSR from these candidate BSRs.

Related Configuration

↘ Configuring Candidate BSRs

By default, candidate BSRs are not configured.

Run **ip pim bsr-candidate** *interface-type interface-number* [*hash-mask-length* [*priority-value*]] to configure or cancel the configuration of candidate BSRs.

Through bootstrap packet (BSM) learning and competition of candidate BSRs, a unique BSR is generated for the PIM-SM domain.

↘ Configuring BSR Borders

By default, BSR borders are not configured.

Run **ip pim bsr-border** to configure or cancel the configuration of BSR borders.

After this command is configured, BSMs received by the interface will be discarded and will not be forwarded by this interface, preventing BSM flooding.

↘ Filtering BSMs

By default, BSMs from the BSR are not filtered.

Run **ip pim accept-bsr list** { <1-99> | <1300-1999> | *WORD* } to configure whether to filter BSMs.

If this function is enabled, only legible BSMs are received by the interface; if this function is disabled, all the external BSMs will be received by the device running PIM-SM.

↘ Configuring Legible C-RP Addresses and the Multicast Groups They Serve for a Candidate BSR

By default, Candidate-RP-Advertisement (C-RP-Adv) packets are not filtered by a candidate BSR.

Run **ip pim accept-crp list** { <100-199> | <2000-2699> | *WORD* } to configure whether to filter C-RP-Adv packets.

If this function is enabled, C-RP addresses and corresponding multicast groups are filtered by a candidate BSR. If this function is disabled, all external C-RP-Adv packets are received by a candidate BSR.

↘ Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

By default, a candidate BSR cannot receive a C-RP-ADV packet whose prefix-count is 0.

Run **ip pim accept-crp-with-null-group** to configure whether to receive a C-RP-ADV packet whose prefix-count is 0.

If this function is enabled, a C-RP-ADV packet whose prefix-count is 0 can be received by a candidate BSR. If this function is disabled, a C-RP-ADV packet whose prefix-count is 0 cannot be received by a candidate BSR.

6.3.4 RP Mechanism

On a PIM network, through static RP configuration or dynamic RP election, the location of the RP can be learned by each PIM router. The RP as the root of the RPT, is the point where the RPT is rooted at and RPT data traffic is forwarded from.

Working Principle

All PIM routers in the same PIM domain must be mapped to the same RP as a specific multicast group address. On a PIM network, an RP can be configured as static or dynamic.

↘ Static RP

In static RP configuration, RP addresses are configured directly on PIM routers and these addresses are learnt by the entire PIM network.

↘ Dynamic RP

In a PIM-SM domain, there are candidate RPs that send unicast packets (including RP addresses and the multicast groups they serve) to the BSR, which generates periodic candidate RPs and bootstrap packets of corresponding group addresses. These bootstrap packets are sent hop by hop in the domain, and received and saved by PIM routers, which apply a hash function to map the group addresses to the candidate RP that can provide services. Then the RP corresponds to these multicast group addresses can be confirmed.

Related Configuration

↘ Configuring Static RP Addresses

By default, no RP address is configured.

Run **ip pim rp-address** *rp-address* [*access-list*] to configure a static RP address for a PIM router.

To use static RP addresses, the static RP address of all routers in the PIM-SM domain must be the same, so that the PIM SM multicast routing remains consistent.

✚ Configuring Candidate C-RP Addresses

By default, no C-RP address is configured.

Run **ip pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *access-list*] to configure or cancel a PIM router as a candidate C-RP.

After a candidate RP is configured, it can send periodic C-RP-Adv packets to the BSR, and the information carried by these C-RP-Adv packets will be advertized to all PIM-SMs in the domain, ensuring the uniqueness of RP mapping.

✚ Ignoring the RP Priority in RP-Set

By default, C-RP of the highest priority is configured.

Run **ip pim ignore-rp-set-priority** to select or deselect the RP priority when selecting the corresponding RP of a multicast group.

If you want to select an RP from multiples RPs that serve the same multicast group address, you can run this command to ignore the RP priority. If this command is not configured, RP priority will be considered when two RPs are compared.

6.3.5 Register Information of the Multicast Source

When the multicast source is detected on the network, the source DR sends a register packet to the RP, which obtains the source information and multicast packet.

Working Principle

When a source DR receives a multicast packet from the host directly connected to it, the source DR encapsulates the multicast packet into the register packet, and sends the unicast packet to RP to form an (S, G) entry.

If the RP has an outgoing interface for the forwarding entry, it encapsulates the data packet and forwards the packet to the outgoing interface.

If the RP does not have the forwarding entry of the present group, it generates the (S, G) entry and enables the timer. If the timer times out, the RP sends a Register-Stop packet to the DR to delete the entry. The source DR sends an inspection packet before timeout after it receives the Register-Stop packet.

If no Register-Stop packet is received by the DR, the DR on the timeout data source will encapsulate the multicast data in the register packet and send the unicast packet to the RP.

If a Register-Stop packet is received by the DR, time-delay will be performed once again, and an inspection packet will be sent before time delay.

Related Configuration

✚ Detecting the Reachability of a Register Packet

By default, the reachability of an RP is not detected.

Run **ip pim register-rp-reachability** to configure or cancel the detection of the reachability of an RP.

You can enable this function if you want to detect whether an RP is reachable for a register packet sent from a DR. After this function is enabled, the DR will detect the reachability of a register packet before it is sent to an RP, namely, the DR will check whether a route to the RP exists in the unicast routing entry and static multicast routing entry. If the route does not exist, the register packet will not be sent.

↘ **Configuring an RP to Filter the Addresses of Register Packets**

By default, all register packets are received an RP.

Run **ip pim accept-register** { **list** *access-list* [**route-map** *map-name*] | **route-map** *map-name* [**list** *access-list*] } to configure an RP to filter or cancel the filtering of the source addresses of received register packets.

You can run this command if you want to filter the source addresses of received register packets. If this function is not enabled, all register packets will be received by the RP. If this function is disabled, only the register packets whose source addresses and multicast group addresses included in access control lists (ACLs) are processed; otherwise, the packets will be filtered.

↘ **Limiting the Speed for Sending a Register Packet**

By default, the speed for sending a register packet is not limited.

Run **ip pim register-rate-limit** *rate* to limit or cancel the limitation of the speed for sending a register packet.

If the **no** form of this command is configured, the speed is not limited. This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system.

↘ **Calculating the Checksum of the Entire Register Packet Length**

By default, the checksum of a register packet is calculated as stipulated by the protocol.

Run **ip pim register-checksum-wholepkt** [**group-list** *access-list*] to configure the checksum of the register packet length.

You can enable this function if you want to include the length of encapsulated multicast packets into the checksum of the register packet length. If this function is disabled, the checksum of a register packet is calculated as stipulated by the protocol.

↘ **Configuring an RP to Forward Multicast Data Packets to Downstream Interfaces After Decapsulating Register Packets**

By default, register packets are not decapsulated and multicast packet are not forwarded to interfaces.

Run **ip pim register-decapsulate-forward** to forward or cancel the forwarding of data packets to downstream interfaces.

You can run this command if you want to decapsulate a register packet and forward the multicast packet. If this function is disabled, the multicast packet will not be forwarded.

↘ **Configuring the Source IP Address of a Register Packet**

By default, the source IP address of a register packet is the same as the interface address of the DR connected to the multicast source.

Run **ip pim register-source** { *local_address* | *Interface-type interface-number* } to configure the source IP address.

You can run this command if you want to configure the source IP address of the register packet sent by a DR. If this function is disabled or the **no** form of this command is used, the source address of the register packet will be the same as the interface address of the DR connected to the multicast source. If you want to configure *local_address*, the configured address must be reachable for a unicast route. *Interface-type interface-number* can be a typical loopback interface or an interface of other types. The interface address must have been advertised by a unicast route.

✚ Configuring the Suppression Time of a Register Packet

By default, the suppression time of a register packet is 60s.

Run **ip pim register-suppression** *seconds* to configure the suppression time.

If you run this command on a DR, you can change the suppression time of the register packets sent from the DR. If you run this command but does not run **ip pim rp-register-kat** on an RP, the keepalive period of the RP will be changed.

✚ Configuring the Inspection Time of a Null Register Packet

By default, the inspection time is 5s.

Run **ip pim probe-interval** *interval-seconds* to configure the inspection time.

In the time interval before the timeout of register packet suppression, the source DR can send a null register packet to an RP. This time interval is called the inspection time, which is 5s by default.

✚ Configuring the Time of a RP KAT

By default, the default value of a keepalive timer (KAT) is used. The default value is calculated as follows: Suppression time of a register packet x 3 + Inspection time of a null register packet.

Run **ip pim rp-register-kat** *seconds* to configure the KAT time.

You can run this command if you want to configure the keepalive time of (S, G) of a register packet sent from an RP.

6.3.6 Creating an RPT

When a group member is detected on the network, the DR connecting to the group members send packets toward the RP to form an RPT. If the multicast source already exists on the network, the packets arrived at the RP can be sent to the group members along the RPT.

Working Principle

To create an RPT, perform the following steps:

A receiver DR receives an IGMP (*, G) include report packet from the receiving end.

If the DR is not the RP of this group (G), the DR will send a (*, G) Join packet toward the RP. The router receiving this (*, G) Join packet will send the packet hop by hop until it is received by the RP, which means that the RP has joined the RPT.

When the data source host sends the multicast data to a group, the source data is encapsulated in the register packet, and sent from the source DR to the RP in unicast mode. Then the RP decapsulates the register packet, takes the data packets out, and forwards these packets to each group member along the RPT.

The RP sends the (S, G) Join packets along the data source to join the SPT of this source.

After the SPT between the RPs to the source DR is created, the data packets from the data source will be sent decapsulated to the RPs along the SPT.

When the first multicast data packet arrives at an RP along the SPT, the RP sends a Register-Stop packet to the source DR to stop sending a register packet. After the source DR receives the Register-Stop packet, it stops encapsulating a register packet and sends the packet along the SPT to the RP, which will forwards the packet to each group member.

Related Configuration

↘ Configuring the Interval for Sending a Join/Prune Packet

By default, the interval for sending a Join/Prune packet is 60s.

Run **ip pim jp-timer** *seconds* to configure the interval for sending a Join/Prune packet.

You can run this command to configure the interval for sending a Join/Prune packet. If not configured, the value will be a default 60s.

6.3.7 Creating an SPT

When data packets arrive at the DR connecting to group members, the DR sends these packets toward the multicast source to form an SPT, and multicast packets are sent to group members along the SPT. In this way, the burden on RP in the RPT is reduced, and the source DR will arrive at the receiver DR with less hops.

Working Principle

To create an SPT, perform the following steps:

The receiver DR sends (*, G) Join packets toward the source DR along the SPT, and (*, G) Join packets are then send hop by hop until they are received by the source DR, forming an SPT.

Related Configuration

By default, SPT switchover is not enabled.

Run **ip pim spt-threshold** [**group-list** *access-list*] to configure whether to switch to an SPT.

If this function is enabled, upon the reception of the first (S, G) packet, a PIM Join packet is triggered, and an SPT is created. If **group-list** is specified, all the specified groups will be switched to the SPT. If the **no** form of this command is used and **group-list** is not specified, an RPT will not be switched to an SPT, and the DR will remain in the RPT and send a Prune packet toward the source DR; if the **no** form of this command is used and **group-list** is specified, and that the ACLs have been configured, it means that the association between **group-list** and the ACLs is canceled, and all the groups are allowed to switch from an RPT to an SPT.

6.3.8 ASM and SSM

A PIM router can provide multicast services of both ASM model and SSM model at the same time. SSM model applies to the groups whose addresses are within the range of the SSM addresses. For other groups, use ASM model. In an ASM model,

only the multicast group (G) is specified for a multicast receiver, and the multicast source (S) is not specified. In an SSM model, both the multicast source (S) and multicast group (G) can be specified for a multicast receiver.

Working Principle

! To realize SSM in an IPv4 router, IGMPv3 needs to be applied for managing membership between the host and devices, and PIM-SM needs to be applied to connect to devices.

In an SSM model, as a multicast receiver has learnt the (S, G) of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement), when a multicast receiver needs to request a multicast service, the multicast receiver can send the IGMP (S, G) Join packet toward the router of last hop. For example, as shown in Figure 6-3, the multicast receiver A sends the IGMP (S, G) Join packet to request the multicast service (S, G). After the router of last hop receives the IGMP (S, G) Join packet, it sends the PIM (S, G) Join packet to the multicast source hop by hop. As shown in Figure 6-3, when R 1 receives the IGMP (S, G) Join packet sent from multicast Receiver 1, R 1 sends the PIM (S, G) Join packet to R 3, which then sends the packet to R 4, thereby forming an SPT connecting the multicast receiver and multicast source.

Figure 6-3 SSM Model

To create an SSM model, the following requirements need to be met:

- A multicast receiver needs to learn the (S, G) of the multicast source in advance, and an IGMP (S, G) Join packet needs to be sent if the receiver needs to request a multicast service.
- IGMPv3 must be run on the interface of the last hop router connecting to the multicast receiver. IGMPv1 and IGMPv2 does not support SSM.
- PIM-SM and SSM must be run on the devices connecting the multicast receiver and multicast source.

! The default range of SSM groups is 232/8. You can run a command to change the value.

An SSM has the following features:

- A multicast receiver can learn the information of the multicast source through a certain channel (for example, by visiting the server or receiving an advertisement) in advance.

- An SSM model is a specific subnet of PIM-SM. It handles only the PIM (S, G) Join and PIM (S, G) Prune packets and discards the RPT-related packets, for example, PIM (*, G) Join/Prune packets, that are within the scope the SSM. If the SSM detects a register packet within the scope, it will respond immediately with a Register-Stop packet.
- If an RP is not required, the election and distribution of RP information are not performed. The MDTs in an SSM are all SPTs.

Related Configuration

ASM is enabled by default.

Run `ip pim ssm { default | range access-list }` to configure whether to switch to SSM.

In SSM, multicast packets can be received by the multicast source directly but not along the RP tree.

6.4 Configuration

Configuration	Description and Command	
Configuring Basic PIM-SM Functions	 (Mandatory) It is used to configure the multicast service.	
	<code>ip multicast-routing</code>	Enables IPv4 multicast routing.
	<code>ip pim sparse-mode</code>	Enables PIM-SM.
	<code>ip pim rp-address</code>	Configures a static RP.
	<code>ip pim rp-candidate</code>	Configures a C-RP.
	<code>ip pim bsr-candidate</code>	Configures a C-BSR.
	<code>ip pim ssm</code>	Enables SSM.
Configuring BSR Parameters	 (Optional) It is used to configure a BSR.	
	<code>ip pim bsr-border</code>	Configures BSR borders.
	<code>ip pim accept-bsr list { <1-99> <1300-1999> WORD }</code>	Configures BSM packets limit on a PIM router.
	<code>ip pim accept-crp list access-list</code>	Configures a C-BSR to inspect the address range of a C-PR.
Configuring RP and DR Parameters	 (Optional) It is used to configure the parameters of an RP or a DR.	
	<code>ip pim ignore-rp-set-priority</code>	Ignores the C-RP priority.
	<code>ip pim register-rp-reachability</code>	Enables the source DR to detect the RP reachability.
	<code>ip pim accept-register list access-list</code>	Configures the range of source register (S, G) addresses.

Configuration	Description and Command	
	ip pim register-rate-limit <i>rate</i>	Limits the speed for sending register packets.
	ip pim register-checksum-wholepkt [group-list <i>access-list</i>]	Calculates the checksum of the entire register packet.
	ip pim register-decapsulate-forward	Enables an RP to decapsulate a register packet and forwards the multicast packet to interfaces.
	ip pim register-source { <i>local_address</i> <i>Interface-type interface-number</i> }	Configures the source IP address of a register packet.
	ip pim register-suppression <i>seconds</i>	Configures the suppression time of a register packet.
	ip pim probe-interval <i>seconds</i>	Configures the inspection time of a null register packet.
	ip pim rp-register-kat <i>seconds</i>	Configures the interval of KATs on an RP.
Configuring the Interval for Sending a Join/Prune Packet	 (Optional) It is used to specify the interval for sending a Join/Prune packet.	
	ip pim jp-timer <i>seconds</i>	Configures the interval for sending a Join/Prune packet.
Configuring the Router of Last Hop to Switch from an RPT to SPT	 (Optional) It is used to switch from SPT to RPT.	
	ip pim spt-threshold [group-list <i>access-list</i>]	Enables SPT switchover.

6.4.1 Configuring Basic PIM-SM Functions

Configuration Effect

- Create a PIM-SM network and provide data sources and user terminals on the network with the IPv4 multicast service.
- Any of ASM or SSM or both models can be configured.

Notes

- PIM-SM needs to use existing unicast routes on the network. Therefore, IPv4 unicast routes must be configured on the network.
- If the PIM network needs to support SSM multicast services, IGMPv3 or SSM mapping must be configured.

Configuration Steps

▾ Enabling IPv4 Multicast Routing

- Mandatory.

- If not specified, IPv4 multicast routing must be enabled on each router.

↳ Enabling PIM-SM

- Mandatory.
- If not specified, PIM-SM must be enabled on the following interfaces: interconnecting router interfaces, interfaces of static RPs, C-RPs, and C-BSRs, and the interfaces connecting to the multicast source and user hosts.

↳ Configuring an RP

- An RP must be configured if ASM multicast services need to be provided on a PIM network.
- An RP can be configured in three models: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and dynamic RP. If both a static RP and dynamic RP are configured, the dynamic RP takes precedence over the static RP.
- Configuring a static RP: If not specified, a static RP should be configured on each router.
- Configuring a dynamic RP: If not specified, a C-RP and C-BSR should be configured on one or multiple routers.

↳ Enabling SSM

- SSM must be enabled if SSM multicast services need to be provided on a PIM network.
- If not specified, SSM must be enabled on every router.

Verification

Send multicast packets from the multicast source to the groups within the address rang of ASM and SSM, and join user hosts to these groups.

- Check whether the user hosts can successfully receive packets from each group.
- Check whether PIM-SM routing entries are created on routers correctly.

Related Commands

↳ Enabling IPv4 Multicast Routing

Command	ip multicast-routing
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling PIM-SM

Command	ip pim sparse-mode
Parameter	N/A

Description	
Command Mode	Interface configuration mode
Usage Guide	PIM interfaces must be at Layer-3, including: routing interfaces, aggregate ports(APs), switch virtual interfaces (SVIs), and loopback interfaces. For all PIM interfaces, IPv4 unicast routes should be reachable.

▾ Configuring a Static RP

Command	ip pim rp-address <i>rp-address</i> [<i>access_list</i>]
Parameter Description	<i>rp-address</i> : Indicates the address of an RP. <i>access_list</i> : Specifies the range of multicast group addresses served by a static RP using an ACL. By default, an RP services all groups.
Command Mode	Global configuration mode
Usage Guide	This command is used to locate a static RP. A static RP should be one with good routing performance. It is recommended that the address of the loopback interface be used as the static RP address. The static RP of all routers must be the same (including the RP address and the range of multicast group addresses it serves). It is recommended that the address of the loopback interface be used as the static RP address. The load can be shared if you configure multiple static RPs to serve different multicast group addresses. It is recommended that the address of the loopback interface be used as the static RP address.

▾ Configuring a C-RP

Command	ip pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>seconds</i>] [group-list <i>access_list</i>]
Parameter Description	<i>interface-type interface-number</i> : Uses the address of this interface as the address of the C-RP. priority <i>priority-value</i> : Competes for the RP priority. A greater value indicates a higher priority. The value ranges from 0 to 255 (192 by default). interval <i>seconds</i> : Indicates the interval for sending a C-RP packet to a BSR. The value ranges from 1 to 16,383 (60 by default). group-list <i>access_list</i> : Specifies the range of multicast group addresses served by a C-RP using an ACL. By default, a C-RP services all multicast groups.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a router as a C-RP. A C-RP should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers.

	<p>It is recommended that the address of the loopback interface be used as the C-RP address.</p> <p>If multiple C-RPs serve the same group, redundancy can be realized.</p> <p>If multiple C-RPs serve the different groups, load can be shared.</p>
--	--

↘ Configuring a C-BSR

Command	ip pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<p><i>interface-type interface-number</i>: Uses the address of this interface as the address of the C-BSR.</p> <p><i>hash-mask-length</i>: Indicates the length of hash mask used to competing for the RP. The value ranges from 0 to 32 (10 by default).</p> <p><i>priority-value</i>: Indicates the priority for competing for the BSR. A greater value indicates a higher priority. The value ranges from 0 to 255 (64 by default).</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to configure a router as a C-BSR.</p> <p>A C-BSR should be one with good routing performance. A C-RP and C-BSR can be on the same router or different routers.</p> <p>It is recommended that the address of the loopback interface be used as the C-BSR address.</p> <p>Configuring multiple C-BSRs can realize redundancy.</p>

↘ Enabling SSM

Command	ip pim ssm { default / range <i>access_list</i> }
Parameter Description	<p>default: Indicates the default range of SSM group addresses, which is 232.0.0.0/8.</p> <p>range <i>access_list</i>: Specifies the range of SSM group addresses using an ACL.</p>
Command Mode	Global configuration mode
Usage Guide	The SSM group addresses configured on all routers must be the same.

↘ Displaying the PIM-SM Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]] [proxy]
Parameter Description	<p><i>group-or-source-address</i>: Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time).</p> <p>proxy: Indicates the RPF vector carried by an entry.</p>
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	<p>Check whether sufficient routing entries are provided.</p> <p>Check the upstream and downstream interface lists and ensure that a correct SPT tree is created.</p>

Configuration Example

▾ Enabling IPv4 Multicast Routing to Support ASM and SSM

<p>Scenario</p> <p>Figure 6-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a IPv4 unicast routing protocol (such as OSPF) on a router, and the router is reachable for the unicast route of a loopback interface. (Omitted) ● Enable IPv4 multicast routing on all the routers. ● Enable PIM-SM on all the interconnected interfaces of the routers, Source, and Receiver. ● Configure C-RP and C-BSR on the loopback interfaces of Router A and Router B, and enable PIM-SM on the loopback interfaces. ● Enable SSM on all routers. ● Enable IGMPv3 on the router interfaces connecting to user terminals. (Omitted)
<p>A</p>	<pre> A# configure terminal A(config)# ip multicast-routing A(config)# ip pim ssm default A(config)# interface GigabitEthernet 0/1 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# interface GigabitEthernet 0/2 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# interface loopback 0 A(config-if)# ip pim sparse-mode A(config-if)# exit A(config)# ip pim rp-candidate loopback 0 </pre>

B	<pre> B# configure terminal B(config)# ip multicast-routing B(config)# ip pim ssm default B(config)# interface GigabitEthernet 0/1 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# interface GigabitEthernet 0/2 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# interface loopback 0 B(config-if)# ip pim sparse-mode B(config-if)# exit B(config)# ip pim bsr-candidate loopback 0 </pre>
Verification	<p>Send packets from S (192.168.1.10) to G 1 (229.1.1.1) and G2 (232.1.1.1). Add the user to G 1 and G 2, and specify the source when the user joins G 2.</p> <ul style="list-style-type: none"> ● Check that multicast packets from S (192.168.1.10) to G 1 and G 2 are received by the user. ● Check the PIM-SM routing entries on Router A and Router B. Verification

Configure the parameters of a Hello packet sent from an interface and run **debug ip pim sparse-mode packet** to display the parameters.

Enable neighbor filtering and run **show ip pim sparse-mode neighbor** to display neighbor information.

Related Commands

↘ Configuring the Interval for Sending Hello Packets

Command	ip pim query-interval <i>interval-seconds</i>
Parameter Description	Indicates the interval for sending Hello packets, Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (30 by default).
Command Mode	Interface configuration mode
Usage Guide	Every time when the interval for sending Hello packets is updated, the holdtime value is automatically updated as 3.5 times of the interval. If the result of the interval for sending Hello packets multiplied by 3.5 is greater than 65, 535, the holdtime value is forcibly updated as 18,725.

↘ Configuring the Prune Propagation Delay

Command	ip pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 32,767 (500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed. As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.

↘ Configuring the Prune Override Interval

Command	ip pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is ms. The value ranges from 1 to 65,535 (2,500 by default).
Command Mode	Interface configuration mode
Usage Guide	Once the prune propagation delay or prune override interval is changed, the Join/Prune packet override interval will be changed.

	As specified by the protocol, the Join/Prune packet override interval must be smaller than the holdtime of a Join/Prune packet; otherwise, short break-up of traffic may be caused. The administrator should maintain such configuration.
--	---

▾ Enabling Suppression Capability of an Interface for Sending Join Packets

Command	ip pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Once Join packets suppression of an interface is enabled, when the present router is to send a Join packet to the upstream neighbor, which has sent a Join packet to its own upstream neighbor, the present router will not send the Join packet; if Join packets suppression is disabled, the Join packet will be sent. When Join packets suppression from downstream receivers are disabled, upstream neighbors will learn how many downstream neighbors are there by counting the Join packets it received, which is called neighbor tracking.

▾ Configuring the Delay for Sending Hello Packets

Command	ip pim triggered-hello-delay <i>interval-seconds</i>
Parameter Description	<i>Seconds</i> : The unit is second. The value ranges from 1 to 5 (5 by default).
Command Mode	Interface configuration mode
Usage Guide	When a PIM interface is enabled or detects a new neighbor, a triggered-hello-delay packet is used to generate a random time. Within the time, the interface sends Hello packets.

▾ Configuring the DR Priority of a Hello Packet

Command	ip pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A greater value indicates a higher priority. The value ranges from 0 to 4,294,967,294 (1 by default).
Command Mode	Interface configuration mode
Usage Guide	<p>A DR may be selected based on the following principles:</p> <p>If all the Hello packets sent from the routers on a local area network (LAN) are configured with priorities, when selecting a DR, the priorities will be compared, and the router with the highest priority will be selected as the DR. If the priority of all routers is the same, their IP addresses will be compared, and the router with the maximum IP address will be selected as the DR.</p> <p>If the priority of the Hello packets sent from a certain router is not configured, the IP addresses of the routers will be compared, and the router with the maximum IP address will be selected as the DR.</p>

▾ Configuring Neighbor Filtering

Command	<code>ip pim neighbor-filter access_list</code>
Parameter Description	<i>access_list</i> : Configures the range of neighbor addresses using a standard IP ACL. The value can be set from 1 to 99 or a string.
Command Mode	Interface configuration mode
Usage Guide	Enabling neighbor filtering can enhance the security of the PIM network and limit the range of legible neighbor addresses. Once a neighbor is filtered out, PIM-SM will not establish peering with it or stop the peering with it.

▾ Displaying the Neighbor Information of an Interface

Command	<code>show ip pim sparse-mode neighbor [detail]</code>
Parameter Description	detail : Displays detailed information.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the interval for sending Hello packets as 50s. ● Configure the prune propagation delay as 400 ms. ● Configure the prune override interval as 3,000 ms. ● Enable suppression capability of an interface for sending Join packets. ● Configure the delay for sending Hello packets as 3s. ● Configure the DR priority of a hello packet as 5.
	<pre>Nodexon# configure terminal Nodexon (config)#int gi 0/1 Nodexon (config-if-GigabitEthernet 0/1)#ip pim query-interval 50 Nodexon (config-if-GigabitEthernet 0/1)#ip pim propagation-delay 400 Nodexon (config-if-GigabitEthernet 0/1)#ip pim override-interval 3000 Nodexon (config-if-GigabitEthernet 0/1)#ip pim triggered-hello-delay 3</pre>
Verification	Run debug ip pim sparse-mode packet to display the parameters of a Hello packet.
	<pre>Nodexon# debug ip pim sparse-mode packet</pre>

	<pre>00:01:49:43: %7: VRF(0): Hello send to GigabitEthernet 0/1 00:01:49:43: %7: Send Hello packet 00:01:49:43: %7: Holdtime: 175 00:01:49:43: %7: T-bit: on 00:01:49:43: %7: Propagation delay: 400 00:01:49:43: %7: Override interval: 3000 00:01:49:43: %7: DR priority: 5 00:01:49:43: %7: Gen ID: 355154648 00:01:49:43: %7: RPF Vector capable</pre>
Configuration Steps	Configure neighbor filtering and set the allowed address range to 192.168.1.0 to 192.168.1.255.
	<pre>Nodexon# configure terminal Nodexon (config)#int gi 0/1 Nodexon (config-if-GigabitEthernet 0/1)# ip pim neighbor-filter 1 % access-list 1 not exist Nodexon(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Nodexon(config)#</pre>
Verification	Display neighbor information before neighbor filtering is configured.
	<pre>Nodexon# show ip pim sparse-mode neighbor Neighbor Interface Uptime/Expires Ver DR Address Priority/Mode 192.168.36.89 GigabitEthernet 0/1 01:12:13/00:01:32 v2 1 / P</pre>
	Display neighbor information after neighbor filtering is configured.
	<pre>Nodexon# show ip pim sparse-mode neighbor</pre>

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.

6.4.3 Configuring BSR Parameters

Configuration Effect

- Configure the address range of BSM packets.

Notes

- Basic PIM-SM functions must be configured.
- C-RPs and C-BSRs must be configured.
- Borders must be configured on the interfaces between domains.

Configuration Steps

↘ Configuring Borders

- Borders must be configured if there are multiple domains.
- Borders are configured on the interfaces separating two domains.

↘ Configuring BSM Packets Limit on a PIM Router

- Optional.
- If not specified, BSM packets limit can be configured on all PIM routers.

↘ Configuring a C-BSR to Inspect the Address Range of a C-PR

- Optional.
- If not specified, C-PR range inspection can be configured on all C-BSRs.

↘ Allowing a C-BSR to Receive a C-RP-ADV Packet Whose Prefix-Count Is 0

- Optional.
- If not specified, this function can be configured on all C-BSRs.

Verification

↘ Border Inspection

Enable basic PIM-SM functions. Configure two routers to be in different domains, configure Router B as the C-BSR, and Router A to receive BSM packets.

Configure the junction of Router A and Router B as the border so that Router A does not receive BSM packets.

↘ Configuring to Inspect BSM Packets Limit on a PIM Router

When basic PIM-SM functions are enabled, and Router B is set as the C-BSR, Router A can receive BSM packets. When the address range of C-BSRs are limited on Router A, BSM packets will not be received by Router A.

↘ Configuring a C-BSR to Inspect the Address Range of a C-PR

When basic PIM-SM functions are enabled, Router B is set as the C-BSR, and Router A as the C-RP, if the address range of the C-RPs is limited on C-BSR, Router B will not receive the packets sent from the C-RPs.

Related Commands

Configuring BSR Borders

Command	<code>ip pim bsr-border</code>
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To prevent BSM flooding, you can configure a BSR border on an interface, so that the BSM packets arriving at this interface will be discarded but not forwarded.

Configuring BSM Packets Limit on a PIM Router

Command	<code>ip pim accept-bsr list { <1-99> <1300-1999> WORD }</code>
Parameter Description	list access-list: Configures the range of BSR addresses using a standard IP ACL. The value can be 1 to 99, 1,300 to 1,999, or a string.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, PIM-SM routers receive only the BSM packets sent from legible BSRs.

Configuring a C-BSR to Inspect the Address Range of a C-PR

Command	<code>ip pim accept-crp list access-list</code>
Parameter Description	list access-list: Specifies the range of C-RP addresses and the multicast group addresses they serve using an extended IP ACL. The value can be 100 to 199, 2,000 to 2,699, or a string.
Command Mode	Global configuration mode
Usage Guide	This command should be configured on a C-BSR. When the C-BSR becomes a BSR, it can set the range of legible C-RP addresses and the range of multicast group addresses they serves.

Displaying BSM Packets Information

Command	<code>show ip pim sparse-mode bsr-router</code>
Parameter Description	-
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

Displaying the Packets of All RPs and the Multicast Group Addresses They Serve

➤ Configuring a C-BSR to Inspect the Address Range of a C-PR, Filtering C-RP Addresses, and Configuring the Range of C-RP Addresses to 192.168.1.1 to 192.168.1.255

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, and the address of the C-BSR as 192.168.6.6. ● On Router B, configure the range of allowed C-RP source addresses to 192.168.1.1 to 192.168.1.255.
	<pre>Nodexon# configure terminal Nodexon(config)# ip pim accept-crp list 100 % access-list 1 not exist Nodexon(config)# access-list 1 permit 192.168.1.0 0.0.0.255 Nodexon(config)#</pre>
Verification	<p>Before configuring C-RP filtering, display the information of all RP groups on Router B.</p>
	<pre>Nodexon#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.8.8(Not self) Info source: 192.168.8.8, via bootstrap, priority 192 Uptime: 00:15:16, expires: 00:02:18 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 18:52:30, expires: 00:02:00</pre>
	<p>After C-RP filtering is configured, display the information of all RP groups on Router B.</p>
	<pre>Nodexon#show ip pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): 224.0.0.0/4 RP: 192.168.5.5(Self) Info source: 192.168.6.6, via bootstrap, priority 192 Uptime: 21:38:20, expires: 00:02:10</pre>
	<p> After C-RP filtering is configured on a router, only the C-RP packets sent from other routers are filtered,</p>

and those sent from the present router are not filtered.
--

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- C-BSRs are not configured.
- The BSR border is not configured on the interfaces of different domains.

6.4.4 Configuring RP and DR Parameters

Configuration Effect

- Ignore the C-RP priority and reselect an RP.
- Detect the reachability of an RP for the source DR.
- Configure the range of (S, G) addresses of source register packets, and allow the ASM to serve only the multicast packets within the range.
- Limit the speed of the source DR for sending register packets.
- Configure the checksum of the register packet length.
- Configure an RP to decapsulate register packets and forward the multicast packets to downstream interfaces.
- Configure the source IP address of a register packet.
- Configure the suppression time of a register packet.
- Configure the inspection time of a null register packet.
- Configure the (S, G) lifetime based on the register packet received by an RP.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

↘ Ignoring the C-RP Priority and Reselecting an RP

- Optional.
- If not specified, the C-RP priority can be disabled on every router.

↘ Detecting the Reachability of an RP for the Source DR

- Optional.
- If not specified, this function can be enabled on the DR connected directly to the data source.

↘ Configuring the Range of Source Register (S, G) Addresses

- Optional.

- If not specified, source register address filtering can be enabled on all C-RPs or static RPs.
- **Limiting the Speed of the Source DR for Sending Register Packets**
- Optional.
- If not specified, this function can be enabled on the source DR.
- **Configuring the Checksum of the Register Packet Length**
- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.
- **Configuring Whether to Forward the Multicast Packet After Decapsulating a Register Packet**
- Optional.
- If not specified, this function can be enabled on all C-RPs or static RPs.
- **Configuring the Source IP Address of a Register Packet**
- Optional.
- If not specified, the source IP address of a register packet can be configured on the DR connected directly to the data source.
- **Configuring the Suppression Time of a Register Packet**
- Optional.
- If not specified, the suppression time of a register packet can be configured on the DR connected directly to the data source.
- **Configuring the Inspection Time of a Null Register Packet**
- Optional.
- If not specified, the inspection time of a null register packet can be configured on the DR connected directly to the data source.
- **Configuring the (S, G) Lifetime Based on the Register Packet Received by an RP**
- Optional.
- If not specified, the (S, G) lifetime can be configured on all C-RPs or static RPs.

Verification

➤ Ignoring the C-RP priority

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 200, and C-BSR address as 192.168.6.6.

- Run **show ip pim sparse-mode rp 233.3.3.3** to display the RPs of the present group.

↘ Enabling the Source DR to Detect RP Reachability

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the C-RP address as 192.168.5.5, priority as 192, and C-BSR address as 192.168.6.6. Enable Router B to detect RP reachability.

- Run **show running-config** to check whether the preceding configurations take effect.

↘ Configuring the Range of Source Register (S, G) Addresses

On Router A, configure the C-RP address as 192.168.8.8, and default priority as 192. On Router B, configure the address of the C-BSR as 192.168.6.6. Configure the source address a 192.168.1.100 and the multicast group address as 233.3.3.3. On Router A, configure the range of allowed source multicast group addresses to 192.168.2.0 to 192.168.2.255.

- Run **show ip pim sparse-mode mroute** to display the (S, G) entry.

↘ Limiting the Speed of the Source DR for Sending Register Packets

Configure the speed of Router B for sending register packets, and run **show ip pim sparse-mode track** to display the number of packets that has been sent.

↘ Configuring the Checksum of the Register Packet Length

On Router A, configure to calculate the checksum of the entire register packet length but not just the packet header. Run **show running-config** to check the configuration.

↘ Forwarding an RP Register Packet After It Is Decapsulated

On Router A, configure to forward a register packet after it is decapsulated. Run **show running-config** to display the configuration.

↘ Configuring the Source IP Address of a Register Packet

Configure the source address of a register packet on Router B, and run **show running-config** to display the configuration.

↘ Configuring the Suppression Time of a Register Packet and the Inspection Time of a Null Register Packet

On Router B, configure the suppression time and inspection time of a register packet, and run **show ip pim sparse-mode track** to display the configuration.

↘ Configuring an RP to Receive Register Packets and the (S, G) Lifetime

On Router A, configuring an RP to receive register packets and the (S, G) lifetime, and run **show ip pim sparse-mode mroute** to display the maximum (S, G) lifetime.

Related Commands

↘ Ignoring the C-RP priority

Command	ip pim ignore-rp-set-priority
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Displaying the RP Corresponding to a Group

Command	show ip pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed multicast group address.
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	N/A

▾ Enabling the Source DR to Detect RP Reachability

Command	ip pim register-rp-reachability
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, the source DR will detect the RP reachability before sending a register packet. If the RP is unreachable, the packet will not be sent.

▾ Configuring the Range of Source Register (S, G) Addresses

Command	ip pim accept-register { list <i>access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>access-list</i>] }
Parameter Description	list <i>access-list</i> : Configures the range of (S, G) addresses using an extended IP ACL. The value can be 100 to 199, 2,000 to 2699, or a string. route-map <i>map-name</i> : Configures the range of (S, G) addresses using a route map.
Command Mode	Global configuration mode
Usage Guide	This command is run on a static RP or a C-RP to specify the source address and multicast group address of a register packet.

▾ Displaying a Multicast Routing Entry

Command	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter Description	<i>group-or-source-address</i> : Indicates a multicast group address or source address (the two addresses cannot be multicast group addresses or source addresses at the same time).
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode

Mode	
Usage Guide	You can specify either a multicast group address or source address, or both a multicast group address and source address; or you can specify neither a multicast group address nor source address. The two addresses cannot be multicast group addresses or source addresses at the same time.

▾ Limiting the Speed of the Source DR for Sending Register Packets

Command	ip pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the maximum number of register packets that can be sent each second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	This command takes effect for only the register packet of each (S, G) packet, but not all the register packets in the entire system. Enabling this command can reduce the burden on the source DR and RPs. Only the packets within the speed limit can be sent.

▾ Displaying the Counters of PIM-SM Packets

Command	show ip pim sparse-mode track
Parameter Description	-
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	The start time for counting PIM-SM packets is automatically enabled upon system startup. Run clear ip pim sparse-mode track to reset the start time and clear the PIM-SM packet counters.

▾ Calculating the Checksum of the Entire Register Packet Length

Command	ip pim register-checksum-wholepkt [group-list <i>access-list</i>]
Parameter Description	group-list <i>access-list</i> : Configures the multicast group addresses applicable to this configuration using an ACL. <i>access-list</i> : The value can be set to 1 to 99, and 1300 to 1999. It also supports the naming of the ACL.
Command Mode	Global configuration mode
Usage Guide	You can enable this function if you want to calculate the length of the entire PIM-SM packet, including that of the multicast packet encapsulated in the register packet, but not just the length of the PIM-SM packet header. If group-list <i>access-list</i> is specified, this configuration takes effect for all multicast group addresses.

▾ Enabling an RP to Decapsulate a Register Packet and Forward the Multicast Packet to Interfaces

Command	ip pim register-decapsulate-forward
----------------	--

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is configured on a static RP or a C-RP. It is used to decapsulate a register packet with multicast packet and forward the multicast packet to interfaces. If there are too many register packets to be decapsulated, the CPU will be greatly burdened. In this case, this function is recommended to be disabled.

↘ Configuring the Source IP Address of a Register Packet

Command	ip pim register-source { <i>local_address</i> <i>Interface-type interface-number</i> }
Parameter Description	<i>local_address</i> : Specifies the source IP address of a register packet. <i>interface-type interface-number</i> : Specifies the IP address of this interface as the source IP address of the register packet.
Command Mode	Global configuration mode
Usage Guide	The specified address must be reachable. When an RP sends a Register-Stop packet, the PIM router corresponds to this address need to respond. Therefore, it is recommended that a loopback address (or other physical addresses) be used. This configuration does not require the enabling of PIM.

↘ Configuring the Suppression Time of a Register Packet

Command	ip pim register-suppression <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the suppression time of a register packet in the unit of seconds. The value ranges from 1 to 65,535 (60 by default).
Command Mode	Global configuration mode
Usage Guide	If you configure this parameter on a DR, the suppression time of a register packet sent from the DR will be changed. If ip pim rp-register-kat is not configured and if you configure this parameter on an RP, the RP keepalive will be changed.

↘ Configuring the Inspection Time of a Null Register Packet

Command	ip pim probe-interval <i>seconds</i>
Parameter Description	<i>vrf vid</i> : Specifies VRF. <i>Seconds</i> : Indicates the inspection time of a null register packet in the unit of seconds. The value ranges from 1 to 65,535 (5 by default).
Command Mode	Global configuration mode

Usage Guide	<p>The inspection time of a null register packet indicates the period of time for sending a null register packet to an RP before the timeout of suppression time.</p> <p>The inspection time cannot exceed half of the suppression time; otherwise, the configuration will not take effect, and a warning message will be displayed. Meanwhile, the result of suppression time multiplied by 3 plus the inspection time cannot exceed 65,535, otherwise, a warning will be displayed.</p>
--------------------	---

▾ Configuring the Interval of KATs on an RP

Command	<code>ip pim rp-register-kat seconds</code>
Parameter Description	<i>Seconds</i> : Indicates the interval of a KAT in the unit of second. The value ranges from 1 to 65,535 (210 by default).
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring the RPs of Corresponding Multicast Group Addresses When the C-RP Priority is Considered or Not Considered

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● On Router A, configure the address of the C-RP as 192.168.8.8. ● On Router B, configure the address of the C-RP as 192.168.5.5, priority as 200, and the address of the C-BSR as 192.168.6.6. ● Display the group corresponding to 233.3.3.3. ● Configure to ignore the C-RP priority on Router B.
	<pre>Nodexon# configure terminal Nodexon(config)# ip pim ignore-rp-set-priority</pre>
Verification	Display the information before you configure to ignore the C-RP priority.
	<pre>Nodexon# show ip pim sparse-mode rp-hash 233.3.3.3 RP: 192.168.8.8 Info source: 192.168.8.8, via bootstrap PIMv2 Hash Value 10(mask 255.192.0.0) RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102 RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709</pre>
	Display the information after you configure to ignore the C-RP priority.

```
Nodexon# show ip pim sparse-mode rp-hash 233.3.3.3

RP: 192.168.5.5

Info source: 192.168.6.6, via bootstrap

PIMv2 Hash Value 10(mask 255.192.0.0)

RP 192.168.8.8, via bootstrap, priority 192, hash value 1084558102

RP 192.168.5.5, via bootstrap, priority 200, hash value 1094656709
```

▾ **Configuring to Inspect the Reachability of a Source RP**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure to inspect the reachability of a source RP.
	<pre>Nodexon(config)# ip pim register-rp-reachability</pre>
Verification	Run show running-config to check whether the following information is displayed.
	<pre>Nodexon(config)#show running-config ip pim register-rp-reachability</pre>

▾ **Configuring the Range of Source Register (S, G) Addresses**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure source address filtering on Router A. The allowed address range is from 192.168.2.0 to 192.168.2.255.

Common Errors

- Basic PIM-SM functions are not configured or the configuration is not successful.
- The (S, G) of register packets is not configured on a C-RP or static RP, or the configuration is not successful.
- The ACL for limiting the (S, G) of register packets is not configured or the range of (S, G) in this ACL is not correctly configured.
- The range of (S, G) of register packets on each C-RP or static RP is not the same.

6.4.5 Configuring the Interval for Sending a Join/Prune Packet

Configuration Effect

- Change the interval for sending a Join/Prune packet to form an RPT or SPT.

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the interval for sending a Join/Prune packet.

Verification

On Router B, configure the interval for sending a Join/Prune packet as 120s. Run **show ip pim sparse-mode mroute** to display the lifetime of the entry.

Related Commands

▾ Configuring the Interval for Sending a Join/Prune Packet

Command	ip pim jp-timer <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the interval for sending a Join/Prune packet. The unit is second. The value ranges from 1 to 65,535 (60 by default).
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring the Interval for Sending a Join/Prune Packet

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the interval for sending a Join/Prune packet.
	<pre>Nodexon(config)#ip pim jp-timer 120</pre>

6.4.6 Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Effect

- Switch from an RPT to SPT

Notes

- Basic PIM-SM functions must be configured.

Configuration Steps

- Configure the router of last hop to switch from an RPT to SPT.

Verification

Configure basic PIM-SM functions first. Configure the source DR to send the data traffic (*, 233.3.3.3), and the receiving end to join group 233.3.3.3 forcibly to form an RPT. Configure the receiver DR to switch from the RPT to SPT forcibly. Run **show running-config** to display the result.

Related Commands

↳ Enabling SPT switchover

Command	ip pim spt-threshold [group-list access-list]
Parameter Description	group-list access-list: Specifies the range of multicast group addresses allowed for SPT switchover using an ACL. access-list: The supported value ranges from 1 to 99 or 1,300 to 1,999. Naming an ACL is also supported.
Command Mode	Global configuration mode
Usage Guide	If group-list access-list is not specified, all groups are allowed to perform SPT switchover.

Configuration Example

↳ Configuring the Router of Last Hop to Switch from an RPT to SPT

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic PIM-SM functions. (Omitted) ● Configure the source DR to send the data traffic of group 233.3.3.3. ● Configure the receiver DR to receive the data traffic of group 233.3.3.3. ● Configure the receiver DR of last hop to switch from an RPT to SPT.
	Nodexon(config)#ip pim spt-threshold
Verification	Run show running-config to display the configuration.
	<pre>! ! ip pim jp-timer 120 ip pim spt-threshold ip pim rp-candidate Loopback 0 ! ! !</pre>

6.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears multicast routing entries.	clear ip mroute { * <i>group-address</i> [<i>source-address</i>] }
Clears the counters of multicast routes.	clear ip mroute statistics { * <i>group-address</i> [<i>source-address</i>] }
Clears the information about dynamic RPs.	clear ip pim sparse-mode bsr rp-set *
Clears the counters of PIM-SM packets.	clear ip pim sparse-mode track

Displaying

Description	Command
Displays the details of BSR information.	show ip pim sparse-mode bsr-router
Displays the PIM-SM information of an interface.	show ip pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local IGMP information about a PIM-SM interface.	show ip pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the information about a PIM-SM multicast routing entry, and displays the RPF vector of a PIM-SM entry using proxy .	show ip pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Displays the information about PIM-SM neighbors.	show ip pim sparse-mode neighbor [detail]
Displays the information about the next hop of PIM-SM obtained from the NSM.	show ip pim sparse-mode nexthop
Displays the information about the RP corresponding the multicast group address <i>group-address</i> .	show ip pim sparse-mode rp-hash <i>group-address</i>
Displays the information about all the RPs and the groups they serve.	show ip pim sparse-mode rp mapping

Description	Command
Displays the number of PIM-SM packets sent and received since the statistic start time.	show ip pim sparse-mode track

7 Configuring PIM-SMv6

7.1 Overview

Protocol Independent Multicast (PIM) is a multicast routing protocol.

PIM does not rely on a specific unicast routing protocol. It uses the unicast routing table established by any unicast routing protocol to complete the reverse path forwarding (RPF) check and establish multicast routes. PIM does not need to transmit and receive multicast route updates. Therefore, the overhead of PIM is much lower than that of other multicast routing protocols.

PIM defines two modes: dense mode and sparse mode. Protocol Independent Multicast Sparse Mode (PIM-SM) is applicable to various network environments.

 PIM-SM running on IPv6 is called PIM-SMv6.

Protocols and Standards

- RFC4601: Protocol Independent Multicast -Sparse Mode (PIM-SM)
- RFC5059: Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)
- RFC3962: Protocol Independent Multicast - Dense Mode protocol
- RFC4607: Source-Specific Multicast for IP

7.2 Applications

Application	Description
ASM Implementation by Using PIM-SMv6	A receiver receives packets from any multicast source.
SSM Implementation by Using PIM-SMv6	A receiver selects a multicast source.
Application Example of an Embedded RP	An embedded RP address is configured within the IPv6 multicast group address.
PIM-SMv6 Application in a Hot Backup Environment	The multicast PIM-SMv6 protocol runs in a hot backup environment.

7.2.1 ASM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from any multicast source.

Figure 7-1

Remarks	<p>R1 is directly connected to the multicast source.</p> <p>R2 is configured as a rendezvous point (RP).</p> <p>R3 is directly connected to Receiver A.</p> <p>R4 is directly connected to Receiver B.</p>
----------------	--

Deployment

- Run the Open Shortest Path First for IPv6 (OSPFv6) protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Run the Internet Group Management Protocol version 6 (IGMPv6) protocol in a user host network segment to implement group member management.

7.2.2 SSM Implementation by Using PIM-SMv6

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, receivers receive packets from a specific multicast source.

Figure 7-2

Remarks	<p>R1 is directly connected to the multicast source.</p>
----------------	--

	<p>R2 is configured as an RP.</p> <p>R2 is directly connected to Receiver A.</p> <p>R2 is directly connected to Receiver B.</p>
--	---

Deployment

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the source-specific multicast (SSM) function of the PIM-SMv6 protocol to implement the SSM function.
- Run the Internet Group Management Protocol version 3 (IGMPv3) in a user host network segment to implement group member management.

7.2.3 Application Example of an Embedded RP

Scenario

The multicast service is provided only in one domain.

As shown in the following figure, an RP address is configured for R2 to make the router become an embedded RP.

Figure 7-3

Remarks	<p>R1 is directly connected to the multicast source.</p> <p>R2 is configured as an RP.</p> <p>R2 is directly connected to Receiver A.</p> <p>R2 is directly connected to Receiver B.</p> <p>R2 is configured as an embedded RP.</p>
----------------	---

Deployment

- Run the OSPFv6 protocol in the domain to implement unicast routing.
- Run the PIM-SMv6 protocol in the domain to implement multicast routing.
- Enable the SSM function of the PIM-SMv6 protocol to implement the SSM function.
- Run the IGMPv3 protocol in a user host network segment to implement group member management.
- Configure the RP address and embedded RP on R2.

7.2.4 PIM-SMv6 Application in a Hot Backup Environment

Scenario

In a hot backup environment, run PIM-SMv6. A device performs hot backup switching to ensure that traffic is not interrupted.

Figure 7-4

Remarks	R1 is connected to the video server, R2 is directly connected to the receiver, and R2 runs in hot backup mode. A Layer-3 multicast protocol runs on R1 and R2.
----------------	---

Deployment

- Run OSPF on R1 and R2 to implement unicast routing.
- Run PIM-SMv6 on R1 and R2 to implement multicast routing.
- Make R2 run in two-node cluster hot backup mode.

Remarks	R2 may perform hot backup switching in the hot backup environment. In this case, the query interval of PIM Hello packets (the default value is 30 seconds) needs to be adjusted on R2 because the keepalive timer of the neighbor in PIM Hello packets of R1 may have expired (the default value is 3.5 times the query interval, that is, 105 seconds). The multicast function relies on the unicast function currently, and the multicast function starts convergence after the unicast function convergence is complete. For example, the default graceful restart (GR) convergence time of the unicast function is 120 seconds. It is recommended that the query interval of PIM Hello packets be set to 60 seconds. The keepalive time of the neighbor in PIM Hello packets is 210 seconds. In this scenario, the query interval of PIM Hello packets need to be set with a reference to the GR convergence time of the unicast function and the value of 3.5 times the query interval of PIM Hello packets must be larger than the GR convergence time of the unicast function. In addition, if the convergence time of the unicast function is long, the transmission interval of PIM Join/Prune packets also need to be adjusted, because the keepalive time of PIM Join/Prune packets is 3.5 times the transmission interval of PIM Join/Prune packets. The default keepalive time of
----------------	--

PIM Join/Prune packets is 210 seconds. If R2 is configured as a dynamic RP, the interval for a candidate RP (C-RP) to transmit C-RP notifications also needs to be adjusted. The default transmission interval is 60 seconds and the keepalive time is 2.5 times the transmission interval of C-RP notifications. For example, if the convergence time of the unicast function is longer than 150 seconds, the transmission interval of C-RP notifications needs to be adjusted. In a hot backup environment, it is recommended that the query interval of PIM Hello packets be larger than the default value (30 seconds). Otherwise, the keepalive timer of the neighbor in PIM Hello packets of the peer end times out during hot backup switching.

7.3 Features

Basic Concepts

↘ PIM Router and PIM Interface

Routers where the PIM protocol is enabled are called PIM routers. Interfaces where the PIM protocol is enabled are called PIM interfaces.

Multicast packets are forwarded by PIM routers. The PIM interfaces for receiving multicast packets are called upstream interfaces, and the PIM interfaces for transmitting multicast packets are called downstream interfaces.

Network segments where upstream interfaces are located are called upstream network segments. Network segments where downstream interfaces are located are called downstream network segments.

↘ PIM Network and PIM Domain

PIM routers are connected through PIM interfaces and form a PIM network.

On some PIM interfaces, borders are set to divide a large PIM network into multiple PIM domains. The borders may reject specific multicast packets or limit transmission of PIM messages.

↘ Multicast Distribution Tree, DR, RP

Multicast packets are transmitted from one point to multiple points. The forwarding path presents a tree structure. This forwarding path is called a multicast distribution tree (MDT). MDTs are classified into two types:

- Rendezvous point tree (RPT): Uses the rendezvous point (RP) as the root and designated routers (DRs) connected to group members as leaves.
- Shortest path tree (SPT): Use the DR connected to a multicast source as the root and the RPs or DRs connected to group members as leaves.

DRs and RPs are function roles of PIM routers.

- RPs collect information about multicast sources and group members in the network.
- The DR connected to a multicast source reports multicast source information to the RP and the DRs connected to group members report the group member information to the RP.

↘ (*,G), (S,G)

- (*,G): Indicates the packets transmitted from any source to Group G, routing entries corresponding to the packets, and forwarding path (RPT) corresponding to the packets.
- (S,G): Indicates the packets transmitted from Source S to Group G, routing entries corresponding to the packets, and forwarding path (SPT) corresponding to the packets.

ASMP, SSM

PIM-SM supports two multicast service models: any-source multicast (ASM) and source-specific multicast (SSM), which are applicable to different multicast address segments.

- ASM: In the ASM model, a user host cannot select a multicast source. The user host joins a multicast group and receives all packets sent from all sources to the multicast group.
- SSM: In the SSM model, a user host can select a multicast source. The user host specifies the source address when joining a multicast group, and then receives packets only from the specified source to the multicast group.

i SSM model requirement: Other network services must be used to enable a user host to know the position of a multicast source in advance so that the user host selects the multicast source.

Overview

Feature	Description
Establishment of PIM Neighbor Relationships	Neighbor relationships are established between PIM routers to form a PIM network.
DR Election	In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to group members. In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.
RP Mechanism	In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP.
Registration Information About a Multicast Source	When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.
RPT Establishment	When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.
SPT Establishment	When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT.
ASM and SSM Models	PIM routers provide multicast services of the ASM model and SSM model. The SSM model is used for groups within the SSM address range, and the ASM model is used for other groups.

7.3.1 Establishment of PIM Neighbor Relationships

Neighbor relationships are established between PIM routers to form a PIM network. Neighbor relationships must be established between PIM routers before other PIM control messages are exchanged or multicast packets are forwarded.

Working Principle

A Hello message is sent by a PIM interface. For the multicast packet for encapsulating the Hello message, the destination address is ff02::d (indicating all PIM routers in the same network segment), the source address is the IP address of the PIM interface, and the time to live (TTL) value is 1.

Hello messages are used to discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.

↘ Discovering PIM Neighbors

PIM routers in the same network segment receive multicast packets with the destination address of ff02::d. In this way, the PIM routers obtain neighbor information and establish neighbor relationships.

When a PIM interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

↘ Negotiating About Protocol Parameters

A Hello message contains multiple protocol parameters, which are described as follows:

- DR_Priority: Indicates the priority of each router interface for DR election. A higher priority means a higher possibility of being elected as the DR.
- Holdtime: Indicates the timeout time in which a neighbor is held in the reachable state.
- LAN_Delay: Indicates the delay for transmitting a Prune message in a shared network segment.
- Override-Interval: Indicates the prune override time carried in a Hello message.

When a PIM router receives a Prune message from an upstream interface, it indicates that other downstream interfaces exist in the shared network segment. If the PIM router still needs to receive multicast data, it must send a Prune Override message to the upstream interface within the time of **Override-Interval**.

$\text{LAN_Delay} + \text{Override-Interval} = \text{PPT}$ (Prune-Pending Timer). After a PIM router receives a Prune message from a downstream interface, it does not immediately perform pruning but waits for PPT timeout. After the PPT times out, the PIM router performs pruning. Within the time of PPT, if the PIM router receives a Prune Override message from the downstream interface, it cancels pruning.

↘ Maintaining Neighbor Relationships

A Hello message is sent periodically between PIM routers. If a Hello packet is not received from a PIM neighbor within Holdtime, the neighbor is considered unreachable and is deleted from the neighbor list. Any changes in PIM neighbors will cause multicast topology changes in the network. If an upstream neighbor or a downstream neighbor in an MDT is unreachable, multicast routing re-convergence is performed again and the MDT is migrated.

Related Configuration

↳ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, candidate - rendezvous point (C-RP), or candidate – bootstrap router (C-BSR), the corresponding protocol role does not take effect.

↳ Adjusting the Transmission Interval of Hello Messages on an Interface

By default, Hello messages are transmitted at an interval of 30 seconds.

Run the **ipv6 pim query-interval** *seconds* command to adjust the transmission interval of Hello messages on an interface. The value ranges from 1 to 65,535.

A larger value of *interval-seconds* means a larger transmission interval of Hello messages and a smaller value of *interval-seconds* means a smaller transmission interval of Hello messages.

7.3.2 DR Election

In the shared network segment connected to group members, DR election is conducted among PIM neighbors to elect the DR connected to the group members.

In the shared network segment connected to a multicast source, DR election is conducted among PIM neighbors to elect the DR connected to the multicast source.

The DR transmits the Join/Prune message in the MDT root node direction for the directly connected group members, or transmits data of the directly connected multicast source to the MDT.

Working Principle

The neighbor IP address and DR priority are obtained from Hello packets of neighbors during establishment of PIM neighbor relationships, so as to elect the DR.

The key of DR election is the DR priorities and IP addresses of interfaces.

↳ Interface DR Priority

A higher interface DR priority means a higher probability that a PIM router is successfully elected as the DR during the DR election.

↳ Interface IP Address

If interfaces of PIM routers share the same DR priority during DR election, IP addresses of neighbors are compared. A larger IP address means a higher probability that a PIM router is successfully elected as the DR.

Related Configuration

▾ Setting IP Addresses of Interfaces

By default, no IP addresses are configured for interfaces.

Run the **ipv6 address** command to set an IP address for an interface.

When PIM routers share the same DR priority, the PIM router with a larger IP address is elected as the DR.

▾ Enabling the PIM-SMv6 Function on an Interface

By default, the PIM-SMv6 function is disabled on an interface.

Run the **ipv6 pim sparse-mode** command to enable or disable the PIM-SMv6 function on an interface.

The PIM-SMv6 function must be enabled on an interface so that the interface participates in the operation of PIM protocols. If the PIM-SMv6 function is disabled on an interface that functions as a DR, static RP, C-RP, or C-BSR, the corresponding protocol role does not take effect.

▾ Adjusting the DR Priority of an Interface

By default, the DR priority is 1.

Run the **ipv6 pim dr-priority *priority-value*** command to adjust the DR priority of an interface. The priority value ranges from 0 to 4,294,967,294.

The DR priority of an interface is used to elect the DR in the directly connected network segment of the interface. A larger priority value means a higher probability that a PIM router is elected as the DR.

7.3.3 BSR Mechanism

In a PIM network, the bootstrap router (BSR) periodically generates bootstrap messages (BSMs) including information about a series of C-RPs and relevant group addresses. BSMs are transmitted hop by hop in the entire domain. PIM routers throughout the network receive BSMs and record information about C-RPs and the relevant group addresses.

Working Principle

One or more C-BSRs are configured in the PIM-SMv6 domain and the BSR is elected from the candidate BSRs according to certain rules.

Related Configuration

▾ Configuring a C-BSR

By default, no C-BSR is configured.

Run the **ipv6 pim bsr-candidate *interface-type interface-number* [*hash-mask-length* [*priority-value*]]** command to configure or cancel a C-BSR.

C-BSRs elect the globally unique BSR in the PIM-SM domain by means of BSM learning and election. The BSR transmits BSMs.

↘ Configuring the BSR Border

By default, no BSR border is configured.

Run the **ipv6 pim bsr-border** command to configure or cancel the BSR border.

After this command is configured for an interface, the interface immediately discards the received BSMs and does not forward BSMs, thereby preventing BSM flooding. No BSR border is configured if this command is not configured.

↘ Defining the Valid BSR Range

By default, the BSMs of BSRs are not filtered.

Run the **ipv6 pim accept-bsr list** *ipv6_access-list* command to define or cancel the BSR range.

After this command is configured, the valid BSR range is defined. If this command is not configured, the device with the PIM-SMv6 function enabled will receive all BSMs.

↘ Configuring a C-BSR to Restrict the Address Range of Valid C-RPs and the Range of Multicast Groups Served by the C-RPs

A C-BSR receives notifications from all C-RPs.

Run the **ipv6 pim accept-crp list** *ipv6_access-list* command to configure whether to filter notifications from C-RPs.

After this command is configured, the C-BSR restricts the address range of valid C-RPs and the range of multicast groups served by the C-RPs. If this command is not configured, the C-BSR receives notifications from all C-RPs.

↘ Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

By default, a C-BSR does not receive C-RP-ADV packets with prefix-count of 0.

Run the **ipv6 pim accept-crp-with-null-group** command to configure whether to receive C-RP-ADV packets with prefix-count of 0.

After this command is configured, the C-BSR can receive C-RP-ADV packets with prefix-count of 0. If this command is not configured, the C-BSR does not process C-RP-ADV packets with prefix-count of 0.

7.3.4 RP Mechanism

In a PIM network, the RP is statically configured or dynamically elected so that each PIM router knows the position of the RP. The RP serves as the root of the RPT. The RPT establishment and the forwarding of RPT data streams must use the RP as the forwarding point.

Working Principle

All PIM routers in a PIM domain must be able to be mapped to the same RP through a specific multicast group address. RPs are classified into static RPs and dynamic RPs in a PIM network.

↘ Static RP

In static RP configuration, the RP address is directly configured on each PIM router so that all PIM routers in the PIM network know the RP address.

Dynamic RP

C-RPs are also configured in the PIM-SMv6 domain. These C-RPs transmit data packets that contain their addresses and information about multicast groups served by them to the BSR in unicast mode. The BSR periodically generates BSMs that contain information about a series of C-RPs and their group addresses. BSMs are transmitted hop by hop in the entire domain. Devices receive and store these BSMs. The DR at the receive end uses a hash algorithm to map a group address to the C-RP that can serve the group. Then, the RP corresponding to the group address can be determined.

Related Configuration

Setting a Static RP Address

By default, no RP address is configured.

Run the **ipv6 pim rp-address** *ipv6_rp-address* [*ipv6_access-list*] command to configure or cancel a static RP address for a PIM router.

An RP must be configured so as to implement ASM in a PIM-SMv6 network. You can configure a static RP or dynamic RP.

If a static RP is configured in a PIM-SMv6 network, the static RP configuration on all devices in the PIM-SMv6 domain must be consistent to prevent multicast route ambiguity in the PIM-SMv6 domain.

Configuring a C-RP Address

By default, no C-RP address is configured.

Run the **ipv6 pim rp-candidate** *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval-seconds*] [**group-list** *ipv6_access-list*] command to configure or cancel a PIM router as a C-RP.

C-RPs periodically transmit C-RP notifications to the BSR. Information contained in these C-RP notifications is dispersed to all PIM-SMv6 devices in the domain, thereby ensuring the uniqueness of RP mapping.

Ignoring the RP Priority in RP Setting

By default, a C-RP with a higher priority is selected preferentially.

Run the **ipv6 pim ignore-rp-set-priority** command to specify or ignore the RP priority when selecting the RP for a group.

When one RP needs to be selected for a multicast address and multiple RPs can serve this multicast address, use this command if the RP priority needs to be ignored during the RP comparison. If this command is not configured, the RP priority will be considered during the RP comparison.

Configuring the Static RP First

By default, a dynamic C-RP is adopted preferentially.

Run the **ipv6 pim static-rp-preferred** command to select the static RP first during RP selection.

After this command is configured, the static RP is adopted first. If this command is not configured, a C-RP is adopted first.

Configuring the Embedded RP Function

By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

Run the **ipv6 pim rp embedded [group-list *ipv6_acl_name*]** command to enable the embedded RP function.

The embedded RP function is the peculiar RP discovery mechanism of IPv6 PIM. This mechanism uses the IPv6 multicast address where the RP address is embedded, to enable a multicast device to directly extract the RP address from the multicast address. By default, the embedded RP function is enabled for all IPv6 multicast group addresses where the RP address is embedded.

7.3.5 Registration Information About a Multicast Source

When a multicast source arises in a network, the DR connected to the multicast source transmits the Register packet to the RP so that the RP obtains information about the multicast source and multicast packets.

Working Principle

The DR at the data source end receives a multicast data packet from the directly connected host, and encapsulates the multicast data into a Register message. Then, it transmits the Register message to the RP in unicast mode. The RP generates the (S,G) entry.

If the forwarding entry contains an outgoing interface on the RP, the RP forwards the encapsulated data packet to the outgoing interface.

If the RP does not have the forwarding entry of the current group, it starts the (S,G) entry start timer. After the timer expires, the RP transmits the Register-Stop message to the DR and deletes the entry. After the DR at the data source end receives the Register-Stop message, the DR transmits the probing packet before the Register-Stop message timer expires.

If the DR does not receive the Register-Stop message, after the timer expires, the DR at the data source end encapsulates the multicast data into the Register message and transmits it to the RP in unicast mode.

If the DR receives the Register-Stop message, it re-starts the delay and re-transmits the probing packet before the delay expires.

Related Configuration

▾ Configuring Reachability Detection of RP Register Packets

By default, the RP reachability is not detected.

Run the **ipv6 pim register-rp-reachability** command to set or cancel the RP reachability detection.

If the RP reachability needs to be detected for the Register packet transmitted from the DR to the RP, you can configure this command. After this command is configured, the RP reachability is detected before the DR transmits the Register packet to the RP. That is, the DR queries the unicast routing table and static multicast routing table to check whether a route reachable to the RP exists. If no, the DR does not transmit the Register packet.

▾ Configuring the RP to Filter Register Packets

By default, the RP allows every received Register packet.

Run the **ipv6 pim accept-register { list *ipv6_access-list* [route-map *map-name*] | route-map *map-name* [list *ipv6_access-list*] }** command to enable or disable the RP to filter received Register packets.

To filter received Register packets on the RP, configure this command. If this command is not configured, the RP allows every received Register packet. If this command is configured, only Register packets whose source addresses and group addresses are allowed by the ACL are processed. Otherwise, the Register packets are filtered out.

▾ Configuring the Transmission Rate Limit for Register Packets

By default, the transmission rate of Register packets is not limited.

Run the **ipv6 pim register-rate-limit** *rate* command to configure whether to limit the transmission rate of Register packets.

If **no** is set in this command, the transmission rate is not limited. This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the transmission rate of Register packets of the entire system.

▾ Configuring the Checksum Calculation of a Register Packet Based on the Entire Register Packet

By default, the checksum in a Register packet is calculated in default mode specified in the protocol.

Run the **ipv6 pim register-checksum-wholepkt** [**group-list** *ipv6_access-list*] command to set the packet length for checksum calculation.

If the entire PIM protocol packet including the encapsulated multicast data packet is used for checksum calculation of a Register packet, use this command. If this command is not configured, the checksum in a Register packet is calculated in default mode specified in the protocol.

▾ Configuring the Source Address of Register Packets

By default, the source address of Register packets uses the address of the DR interface connected to a multicast source.

Run the **ipv6 pim register-source** { *ipv6_local_address* | *interface-type interface-number* } command to configure the source address of Register packets.

To configure the source address of Register packets transmitted from the DR, use this command. If this command is not configured or **no** is set in this command, the source address of Register packets uses the address of the DR interface connected to a multicast source. If the address parameter of this command is used, the configured address must be a reachable unicast route. If the interface parameter of this command is used, this interface may be a loopback interface or an interface of other types and the interface address must be an advertised unicast route.

▾ Configuring the Suppression Time of Register Packets

The default suppression time of Register packets is 60 seconds.

Run the **ipv6 pim register-suppression** *seconds* command to configure the suppression time.

If this command is used to configure the suppression time of Register packets, configuring the value on the DR will change the suppression time of Register packets on the DR. If the **ipv6 pim rp-register-kat** *seconds* command is not configured, defining the value on the RP will change the keepalive time on the RP.

▾ Configuring the Probing Time of NULL Register Packets

The default probing time is 5 seconds.

Run the **ipv6 pim probe-interval** *interval-seconds* command to set the probing time.

The source DR transmits the NULL-Register packet to the RP within a certain interval prior to the timeout of the suppression time of the Register packet. This interval is the probing time. The default probing time is 5 seconds.

✚ Configuring the Time Value of the RP KAT Timer

By default, the KAT default value is used. KAT default value = Registration suppression time x 3 + Registration detection time.

Run the **ipv6 pim rp-register-kat** *seconds* command to set time of the KAT timer.

To configure the keepalive time of Register packets from the (S,G) multicast group address on the RP, use this command.

7.3.6 RPT Establishment

When a group member arises in a network, the DR connected to the group member transmits the Join packet in the RP direction to establish an RPT. If there is a multicast source in the network, the multicast packet transmitted to the RP can reach the group member along the RPT.

Working Principle

The RPT establishment process is as follows:

1. The DR at the receive end receives an MLD (*,G)Include report packet from a receiver.
2. If the DR at the receive end is not the RP of Group G, the DR at the receive end transmits one (*,G)join packet in the RP direction. The upstream device that receives the (*,G)join packet transmits the (*,G)join packet in the RP direction. The (*,G)join packet is transmitted hop by hop till the RP of Group G receives the (*,G)join packet, indicating that the DR at the receive end joins the RPT.
3. When the data source host transmits multicast data to a group, the source data is encapsulated into the Register message and is transmitted to the RP in unicast mode by the DR at the data source end. The RP decapsulates the Register message, retrieves the data packet, and then forwards it to each group member along the RPT.
4. The RP transmits the (S,G)join packet to the DR at the data source end to join the SPT of this data source.
5. After the SPT from the RP to the DR at the data source end is established, data packets from the data source are transmitted to the RP along the SPT without encapsulation.
6. When the first multicast data packet reaches the RP along the SPT, the RP transmits the Register-Stop message to the DR at the data source end to enable the DR to stop the encapsulation of Register packets. After the DR at the data source end receives the Register-Stop message, it does not encapsulate the Register packets but transmits the Register packets to the RP along the SPT of the data source. The RP forwards the Register packets to each group member along the RPT.

Related Configuration

✚ Configuring the Transmission Interval of Join/Prune Packets

The default transmission interval of Join/Prune packets is 60 seconds.

Run the **ipv6 pim jp-timer** *seconds* command to set the transmission interval of Join/Prune packets.

To change the default transmission interval of Join/Prune packets, configure this command. If this command is not configured, the default transmission interval of Join/Prune packets is 60 seconds.

7.3.7 SPT Establishment

When a data packet reaches the DR connected to a group member, the DR connected to the group member transmits the Join packet in the multicast source direction to establish an SPT. Then, multicast packets are forwarded along the SPT, thereby relieving the load of the RP in the RPT and reducing the number of hops from the DR at the data source end to the receive end.

Working Principle

The SPT establishment process is as follows:

The DR at the receive end transmits the (*,G)join packet to the DR at the source end along the SPT. The (*,G)join packet is transmitted hop by hop till the DR at the source end receives the (*,G)join packet, forming an SPT.

Related Configuration

By default, SPT switching is disabled.

Run the **ipv6 pim spt-threshold [group-list ipv6_access-list]** command to configure whether to start SPT switching.

After this command is configured, when the DR receives the (S,G) packet from the first group member, one PIM Join message is generated and forwarded to the RP to establish a SPT tree. If **group-list** is defined, the defined group is switched from the RPT to the SPT. If **no** is set in this command and **group-list** is not defined, the switching from the RPT to the SPT is disabled and the device redirects to the RPT and transmits one Prune packet to the source. If **no** is set in this command, **group-list** is defined, and the defined ACL is a configured ACL, the ACL associated with **group-list** is cancelled and all groups are allowed to switch from the RPT to the SPT.

7.3.8 ASM and SSM Models

PIM-SM supports two multicast models: ASM and SSM. In the ASM model, a multicast data receiver specifies only to join a multicast group G but does not specify the multicast source S. In the SSM model, a multicast data receiver can specify both the multicast source S and multicast group G.

-
- i** When the SSM model is implemented over IPv6, MLDv2 needs to be used to manage the member relationship between hosts and devices and PIM-SMv6 needs to be used to connect devices.
-

In the SSM model, a multicast receiver learns about the multicast source (S,G) information by means of some channels (such as accessing the server or receiving advertisements) in advance. When the multicast receiver needs to order a multicast service, it directly transmits the MLD(S,G) Join packet to the last-hop device, for example, as shown in the following figure, Multicast Receiver 1 transmits the MLD(S,G) Join packet to order the multicast service (S,G). After receiving the MLD(S,G) Join packet from the multicast receiver, the last-hop device transmits the PIM(S,G) Join packet to the multicast source hop by hop, for example, as shown in the following figure, after receiving the MLD(S,G) Join packet from Multicast Receiver 1, R1 transmits the PIM(S,G) Join packet to R3, which transmits the PIM (S,G) Join packet to R4. As a result, the SPT from the multicast receiver to the multicast source is established.

Figure 7-5

The following conditions need to be met for the implementation of the SSM model:

- A multicast receiver learns about the multicast source (S,G) information beforehand by means of some channels. The multicast receiver initiates the MLD(S,G) Join packet to the desired multicast service.
- MLDv2 must be enabled on the interface of the last-hop device connected to the multicast receiver. MLDv1 does not support SSM.
- PIM-SM and SSM must be enabled on the intermediate devices between the multicast receiver and the multicast source.

i After the SSM function is enabled, the default group range of SSM is FF3x::/32. You can run a command to change the group range of SSM.

The SSM model has the following features:

- In the SSM model, a multicast receiver can learn about the multicast source information in advance by means of some channels (for example, receiving advertisements or accessing a specified server).
- The SSM model is a specific subset of PIM-SM and processes only PIM(S,G) Join and PIM(S,G) Prune messages. It discards RPT-relevant messages within the SSM range, for example, PIM(*,G) Join/Prune messages. For Register packets within the SSM range, it immediately responds with the Register-Stop packet.
- In the SSM model, no RP is required and the election and distribution of RP messages are not required. The established MDT is the SPT in SSM.

7.4 Configuration

7.4.1 Configuring Basic Functions of PIM-SMv6

Configuration Effect

- Create a PIM network to provide the IPv6 multicast service for data sources and user terminals in the network.
- Both or either of the two multicast service models (ASM and SSM) can be supported.

Notes

- PIM-SMv6 needs to use the IPv6 unicast routing function.
- If the PIM network needs to support the multicast service of the SSM model, MLDv3 or SSM Mapping needs to be configured.

Configuration Steps

↳ Enabling the IPv6 Multicast Routing Function

- Mandatory.
- The IPv6 multicast routing function should be enabled on each router unless otherwise specified.

↳ Enabling the PIM-SMv6 Function

- Mandatory.
- The PIM-SMv6 function should be enabled on the following interfaces unless otherwise specified: router interconnection interfaces, interface that function as a static RP, C-RP, or C-BSR, interface for connecting to a multicast source, and interface for connecting to a user host.

↳ Configuring an RP

- If a PIM network needs to support the multicast service of the ASM model, an RP must be configured.
- There are three methods of configuring an RP: configuring only a static RP, configuring only a dynamic RP, and configuring both a static RP and a dynamic RP. If both a static RP and a dynamic RP are configured, the dynamic RP is preferred.
- Configuring a static RP: A static RP should be configured on each router unless otherwise specified.
- Configuring a dynamic RP: A C-RP or C-BSR should be configured on one or more routers unless otherwise specified.

↳ Enabling the SSM

- If a PIM network needs to support the multicast service of the SSM model, the SSM must be enabled.
- The SSM should be enabled on each router unless otherwise specified.

Verification

Make a multicast source in the network send packets to groups within the range of ASM and SSM and make a user host join the groups.

- Check whether the user host can successfully receive packets from each group.
- Check whether correct PIM-SMv6 routing entries are created on routers.

Related Commands

▾ Enabling the IPv6 Multicast Routing Function

Command	ipv6 multicast-routing
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling the PIM-SMv6 Function

Command	ipv6 pim sparse-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	<p>Before enabling the PIM-SMv6 function, enable the multicast routing forwarding function in global configuration mode. Otherwise, multicast data packets cannot be forwarded even if the PIM-SMv6 function is enabled.</p> <p>When the PIM-SMv6 function is enabled, MLD is automatically enabled on each interface without manual configuration.</p> <p>If the message "Failed to enable PIM-SMv6 on <interface name>, resource temporarily unavailable, please try again" is displayed during the configuration of this command, try to configure this command again.</p> <p>If the message "PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!" is displayed during the configuration of this command, the configured number of multicast interfaces reaches the upper limit of multicast interfaces that can be configured on the device. If the PIM-SMv6 function still needs to be enabled on an interface, delete some unnecessary PIM-SMv6 or PIM-DMv6 interfaces.</p> <p>If an interface is of the tunnel type, only the 6Over4 configuration tunnel, 6Over4 GRE tunnel, 6Over6 configuration tunnel, and 6Over6 GRE tunnel support the IPv6 multicast function. The multicast function can also be enabled on tunnel interfaces that do not support the multicast function but no prompts are displayed and multicast packets are neither received nor transmitted.</p> <p>Multicast tunnels can be established only on Ethernet ports. Embedded tunnels and QoS/ACL of multicast</p>

	data are not supported.
--	-------------------------

▾ Configuring a Static RP

Command	ipv6 pim rp-address <i>ipv6_rp-address</i> [<i>ipv6_access-list</i>]
Parameter Description	<i>ipv6_rp-address</i> : Indicates the IPv6 address of an RP. <i>ipv6_access_list</i> : References an IPv6 ACL to restrict the group address range served by the static RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	<p>Multicast static RPs can be configured. A static RP and a C-RP can coexist.</p> <p>Notes:</p> <ol style="list-style-type: none"> 1. If both the BSR mechanism and RP static configuration are effective, the dynamic configuration is preferred. 2. A control list can be used to statically configure the address of an RP for multiple multicast groups (using the ACL) or all multicast groups (without using the ACL), but one static RP address cannot be used multiple times. 3. If multiple static RPs serve the same group, the static RP with a larger IPv6 address is used preferentially. 4. Only multicast groups with the addresses allowed by the ACL are effective. By default, all multicast groups are allowed. 5. After the configuration is complete, the static RP source address will be inserted into the group range-based static RP group tree structure. The multicast static group in each group range maintains the linked list structure of one static RP group. This linked list is arranged in descending order by IPv6 address. When an RP is selected for a group range, the RP with the largest IPv6 address will be selected. 6. When a static RP address is deleted, this address is deleted from all existing groups and an address is selected from the existing static RP tree structure as the RP address.

▾ Configuring a C-RP

Command	ipv6 pim rp-candidate <i>interface-type interface-number</i> [priority <i>priority-value</i>] [interval <i>interval-seconds</i>] [group-list <i>ipv6_access-list</i>]
Parameter Description	<p><i>interface-type interface-number</i>: Indicates an interface name. This interface address is used as the C-RP address.</p> <p>priority <i>priority-value</i>: Specifies the priority of the C-RP. The value ranges from 0 to 255 and the default value is 192.</p> <p>interval <i>seconds</i>: Indicates the interval for transmitting C-RP messages to the BSR, with the unit of seconds. The value ranges from 1 to 16,383 and the default value is 60.</p> <p>group-list <i>ipv6_access-list</i>: References an IPv6 ACL to restrict the group address range served by the C-RP. A named ACL is supported.</p>
Command	Global configuration mode

Mode	
Usage Guide	<p>In the PIM-SMv6 protocol, the RPT created by the multicast routing uses an RP as the root node. After the BSR is elected, all C-RPs periodically transmit C-RP messages to the BSR in unicast mode and then the BSR disperses the messages in the entire PIM domain.</p> <p>To specify an interface as the C-RP of a specific group range, contain the ACL option in this command. Note that the calculation of the group range is based only on the permitted access control entries (ACEs) and denied ACEs are not involved in the calculation.</p> <p>If group-list ipv6_access-list is not carried in the command, all groups are served.</p>

↘ Configuring a C-BSR

Command	ipv6 pim bsr-candidate <i>interface-type interface-number</i> [<i>hash-mask-length</i> [<i>priority-value</i>]]
Parameter Description	<p><i>interface-type interface-number</i>: Indicates an interface name. This interface address is used as the C-BSR address.</p> <p><i>hash-mask-length</i>: Indicates the hash mask length. The value ranges from 0 to 128 and the default value is 126.</p> <p><i>priority-value</i>: Indicates the priority. The value ranges from 0 to 255 and the default value is 64.</p>
Command Mode	Global configuration mode
Usage Guide	<p>A unique BSR must exist in a PIM-SMv6 domain. The BSR collects and advertises RP information. The unique well-known BSR is elected from multiple C-BSRs by means of BSMs. All C-BSRs consider that they are the BSR before knowing the BSR information. They periodically transmit BSMs that contain the BSR address and priority in the PIM-SMv6 domain.</p> <p>This command can be used to enable a device to transmit one BSM to all PIM neighbors by using the allocated BSR address. Each neighbor compares the original BSR address with the address in the received BSM. If the IPv6 address in the received BSM is equal to or larger than its BSR address, the neighbor stores this address as the BSR address and forwards the BSM. Otherwise, the neighbor discards the BSM.</p> <p>The current device deems that it is the BSR till it receives a BSM from another C-BSR and learns that the C-BSR has a higher priority (or the same priority but a larger IPv6 address).</p>

↘ Enabling the SSM

Command	ipv6 pim ssm { default / range <i>ipv6_access-list</i> }
Parameter Description	<p>default: The default group address range of SSM is FF3x::/32.</p> <p>range <i>ipv6_access-list</i>: References an IPv6 ACL to restrict the SSM group address range. A named ACL is supported.</p>
Command Mode	Global configuration mode
Usage Guide	To apply SSM in a PIM-SMv6 network, you must configure this command.

↘ Displaying the PIM-SM Routing Table

Command	show ipv6 pim sparse-mode mroute [group-or-source-address [group-or-source-address]]
Parameter Description	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both group address and source address can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

Configuration Example

Creating the IPv6 Multicast Service on an IPv6 Network to Support ASM and SSM

Scenario Figure 7-6	
Configuration Steps	<ul style="list-style-type: none"> ● Configure an IPv6 unicast routing protocol (such as OSPFv6) on the routers and ensure that the unicast routes of the loopback interfaces are reachable. (Omitted) ● Enable the IPv6 multicast routing function on all routers. ● Enable the PIM-SMv6 function on device interconnection interfaces, interface for connecting to the user host, and interface for connecting to the multicast source. ● Configure a C-RP and a C-BSR on the loopback interfaces of Router A and Router B. Enable the PIM-SMv6 function on the loopback interfaces. ● Enable SSM on all routers. ● Enable MLDv3 on the router interface for connecting to the user host. (Omitted)
A	<pre>switch(config)#ipv6 multicast-routing switch(config)#ipv6 pim ssm default switch(config)#int gi 0/2 switch(config-if-GigabitEthernet 0/2)#ipv6 add 2000::2/64 switch(config-if-GigabitEthernet 0/2)#ipv6 pim sparse-mode</pre>

	<pre> switch(config-if-GigabitEthernet 0/2)#exit switch(config)#int gi 0/1 switch(config-if-GigabitEthernet 0/1)#ipv6 add 1000::1/64 switch(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode switch(config-if-GigabitEthernet 0/1)#exit switch(config)#int Loopback 0 switch(config-if-Loopback 0)#ipv6 add 3000::5/64 switch(config-if-Loopback 0)#ipv6 pim sparse-mode switch(config-if-Loopback 0)#exit switch(config)#ipv6 pim rp-candidate Loopback 0 </pre>
B	<pre> Nodexon(config)#ipv6 multicast-routing Nodexon(config)#ipv6 pim ssm default Nodexon(config)#int gi 0/2 Nodexon(config-if-GigabitEthernet 0/2)#ipv6 add 2000:: 1/64 Nodexon(config-if-GigabitEthernet 0/2)#ipv6 pim Nodexon(config-if-GigabitEthernet 0/2)#exit Nodexon(config)#int gi 0/1 Nodexon(config-if-GigabitEthernet 0/1)#ipv6 add 1100:: 1/64 Nodexon(config-if-GigabitEthernet 0/1)#exit Nodexon(config-if-GigabitEthernet 0/1)#ipv6 pim sparse-mode Nodexon(config)#int Loopback 0 Nodexon(config-if-Loopback 0)#ipv6 add 5000::5/64 Nodexon(config-if-Loopback 0)#exit Nodexon(config-if-Loopback 0)#ipv6 pim sparse-mode </pre>
Verification	<p>Nodexon(config)#ipv6 pim bsr-candidate Loopback 0 Make Source(2000::2/64) send packets to G1(FF16::1) and make User join G1.</p> <ul style="list-style-type: none"> ● Check the multicast packets received by the User. The User should be able to receive multicast packets from G1. ● Check PIM-SMv6 routing tables on Router A and Router B. Entries should exist on the PIM-SMv6 routing tables.

Common Errors

- IPv6 unicast routing is incorrectly configured.
- IPv6 multicast routing is not enabled on a router.
- SSM is not enabled on a router or the SSM group address range of the router is different from that of other routers.
- PIM-SMv6 is not enabled on an interface (for example, interface that is specified as a C-RP or C-BSR, or interface that functions as the gateway of a user host or multicast source).
- MLDv3 is not enabled on an interface connected to a user host.
- No RP is configured in the network.
- No static RP is configured on a router or the configured static RP is different from that on other routers.
- A C-RP is configured but no C-BSR is configured in the network.
- The unicast route to the static RP, C-RP, or C-BSR is unreachable.

7.4.2 Configuring PIM Neighbor Parameters

Configuration Effect

- Negotiate about protocol parameters and adjust parameters in a Hello packet.
- PIM routers discover neighbors, negotiate about protocol parameters, and maintain neighbor relationships.
- Protect neighbor relationships to restrict neighbors.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Set parameters on each PIM router interface unless otherwise specified.

Verification

Set parameters in a Hello packet on an interface and run the **debug ipv6 pim sparse-mode packet** command to check parameters in the Hello packet.

Set neighbor filtering and run the **show ipv6 pim sparse-mode neighbor** command to check the neighbor relationship.

Related Commands

▾ Configuring the Transmission Interval of Hello Messages

Command	ipv6 pim query-interval <i>seconds</i>
Parameter Description	Indicates the transmission interval of Hello packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 30 .
Command Mode	Interface configuration mode
Usage Guide	Each time the transmission interval of Hello messages is updated, the Holdtime of Hello messages is accordingly updated according to the following rule: The Holdtime of Hello messages is updated to 3.5 times transmission interval of Hello messages. If the transmission interval of Hello messages multiplied by 3.5 is larger than 65,535, the transmission interval of Hello messages is forcibly updated to 18,725.

▾ Configuring the Propagation Delay for Hello Messages

Command	ipv6 pim propagation-delay <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 32,767 and the default value is 500 .
Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred. This must be maintained and guaranteed by network administrators.

▾ Configuring the Prune Override Interval for Hello Messages

Command	ipv6 pim override-interval <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : The unit is milliseconds. The value ranges from 1 to 65,535 and the default value is 2500 .
Command Mode	Interface configuration mode
Usage Guide	Changing the propagation delay or prune override delay will affect J/P-override-interval. According to the protocol, J/P-override-interval must be smaller than the Holdtime of Join-Prune packets. Otherwise, short flow interruption will be incurred.

▾ Configuring the Interface Joining Suppression Capability for Hello Messages

Command	ipv6 pim neighbor-tracking
Parameter Description	N/A
Command Mode	Interface configuration mode

Mode	
Usage Guide	When the joining suppression capability of an interface is enabled and the local router needs to transmit a Join packet to an upstream neighbor, the Join packet of the local router is suppressed and is not transmitted if the local router receives a Join packet from a neighbor to the upstream router. If the joining suppression capability of the interface is disabled, the local router transmits the Join packet. When the joining suppression capability of a downstream receiver is disabled, the upstream neighbor can accurately know the number of receivers connected to the downstream neighbor through the received Join packet, thereby implementing neighbor tracking.

📌 Configuring the Delay of Sending Out Hello Messages

Command	ipv6 pim triggered-hello-delay <i>seconds</i>
Parameter Description	<i>Seconds</i> : The unit is seconds. The value ranges from 1 to 5 and the default value is 5 .
Command Mode	Interface configuration mode
Usage Guide	When an interface is enabled or detects a new neighbor, the Triggered-Hello-Delay message is used to generate a random time period. Within the time period, the interface sends Hello packets.

📌 Configuring the DR Priority for Hello Messages

Command	ipv6 pim dr-priority <i>priority-value</i>
Parameter Description	<i>priority-value</i> : Indicates the priority. A larger value means a higher priority. The value ranges from 0 to 4,294,967,294 and the default value is 1 .
Command Mode	Interface configuration mode
Usage Guide	The process of selecting a DR is as follows: The priority parameter is set for Hello packets of devices in the same LAN. The priority is compared for the selection of a DR. The device with a higher priority is the DR. If multiple devices share the same priority, the device with a larger IP address is the DR. When the priority parameter is not set for Hello packets of a device in a LAN, the device with a larger IP address is elected as the DR in the LAN.

📌 Configuring Neighbor filtering

Command	ipv6 pim neighbor-filter <i>ipv6_access-list</i>
Parameter Description	<i>ipv6_access-list</i> : References an IPv6 ACL to restrict the neighbor address range.
Command Mode	Interface configuration mode
Usage Guide	This command can be used to filter neighbors to strengthen the security of the PIM network and restrict the

address range of legitimate neighbors. If a neighbor is rejected by an ACL, PIM-SMv6 will not establish a peering relationship with this neighbor or suspend the peering relationship with this neighbor.

▾ Displaying Neighbor Information About an Interface

Command	show ipv6 pim sparse-mode neighbor [detail]
Parameter Description	detail: Displays details.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the transmission interval of Hello packets of PIM-SMv6 to 50 seconds. ● Set the propagation delay of Hello packets of PIM-SMv6 to 400 milliseconds. ● Set the prune override interval of Hello packets of PIM-SMv6 to 3,000 milliseconds. ● Configure the interface joining suppression capability for Hello messages of PIM-SMv6. ● Set the delay of sending out Hello messages of PIM-SMv6 to 3 seconds. ● Set the DR priority of Hello messages of PIM-SMv6 to 5.
	<pre>switch # configure terminal switch (config)#int gi 0/1 switch (config-if-GigabitEthernet 0/1)#ipv6 pim query-interval 50 switch (config-if-GigabitEthernet 0/1)#ipv6 pim propagation-delay 400 switch (config-if-GigabitEthernet 0/1)#ipv6 pim override-interval 3000 switch (config-if-GigabitEthernet 0/1)#ipv6 pim triggered-hello-delay 3 switch (config-if-GigabitEthernet 0/1)# ipv6 pim dr-priority 5</pre>
Verification	Run the debug ipv6 pim sparse-mode packet command to check parameters in a Hello packet.

	<pre>switch # debug ipv6 pim sparse-mode packet *Jan 2 02:37:55: %7: Hello send to GigabitEthernet 0/2 *Jan 2 02:37:55: %7: Send Hello message *Jan 2 02:37:55: %7: Holdtime: 175 *Jan 2 02:37:55: %7: T-bit: off *Jan 2 02:37:55: %7: Propagation delay: 400 *Jan 2 02:37:55: %7: Override interval: 3000 *Jan 2 02:37:55: %7: DR priority: 5 *Jan 2 02:37:55: %7: Gen ID: 99572792 *Jan 2 02:37:55: %7: Secondary Addresses: *Jan 2 02:37:55: %7: 2000::2</pre>
Configuration Steps	Configure neighbor filtering on an interface to receive neighbor packets with the address of (8000::1/64).
	<pre>switch(config-if-GigabitEthernet 0/2)#ipv6 pim neighbor-filter acl % access-list acl not exist switch(config-if-GigabitEthernet 0/2)#exit switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::1/64 any</pre>
Verification	Before neighbor filtering is configured, display the neighbor information.
	<pre>switch#show ipv6 pim sparse-mode neighbor Neighbor Address Interface Uptime/Expires DR Pri/Mode fe80::21a:a9ff:fe3a:6355 GigabitEthernet 0/2 00:32:29/00:01:16 1 /</pre>
Verification	After neighbor filtering is configured, the neighbor information is blank.
	<pre>switch#show ipv6 pim sparse-mode neighbor</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.

7.4.3 Configuring BSR Parameters

Configuration Effect

- Restrict the range of BSMs.

Notes

- The basic functions of PIM-SMv6 must be configured.
- A C-RP and a C-BSR must be configured.
- The border must be configured on the interface between domains.

Configuration Steps

↘ Configuring the Border

- The border must be configured if there are multiple domains.
- Configure the border the interface between two domains.

↘ Configuring a PIM Router to Restrict BSMs

- Optional.
- This configuration can be performed on a PIM router unless otherwise specified.

↘ Configuring a C-BSR to Restrict the C-PR Range

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

↘ Configuring a C-BSR to Receive C-RP-ADV Packets with prefix-count of 0

- Optional.
- This configuration can be performed on all C-BSRs unless otherwise specified.

Verification

↘ Verifying the Border

Enable the basic functions of PIM-SMv6, set two routers in different domains, and set Router B as a C-BSR. Router A can normally receive BSMs.

Set the common border between Router A and Router B as a border interface. Router A cannot receive BSMs.

↘ Verifying a PIM Router to Restrict BSMs

Enable the basic functions of PIM-SMv6 and set Router B as a C-BSR. Router A can normally receive BSMs. Restrict the C-BSR range on Router A. Router A cannot receive BSMs.

↘ Verifying a C-BSR to Restrict the C-PR Range

Enable the basic functions of PIM-SMv6, set Router B as a C-BSR, set Router A as a C-RP, and restrict the C-RP range on the C-BSR. Router B cannot receive packets from the C-RP.

Related Commands

▾ Configuring the BSR Border

Command	ipv6 pim bsr-border
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The BSR border can be configured on an interface to restrict flooding of BSMs. When this interface receives BSMs, it immediately discards them and BSMs are not forwarded by this interface.

▾ Configuring a PIM Router to Restrict BSMs

Command	ipv6 pim accept-bsr list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the BSR address range. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring a C-BSR to Restrict the C-PR Range

Command	ipv6 pim accept-crp list <i>ipv6_access-list</i>
Parameter Description	list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the address range of the C-RP and the group address range served by the C-RP. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	Configure this command on a C-BSR. When this C-BSR is elected as the BSR, it can restrict the address range of the valid C-RP and the multicast group range served by the C-RP.

▾ Displaying BSMs

Command	show ipv6 pim sparse-mode bsr-router
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

➤ **Displaying All RPs Configured on the Local Device and the Multicast Groups Served by the RPs**

Command	show ipv6 pim sparse-mode rp mapping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

➤ **Configuring the BSR Border**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the BSR border on the juncture interface between Router B and Router A.
	<code>Nodexon(config-if-GigabitEthernet 0/2)#ipv6 pim bsr-border</code>
Verification	Before the BSR border is configured, the BSM information of Router A is displayed as follows:
	<pre>switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch#</pre>
	 Candidate RP: Indicates all C-RPs configured on the local router, excluding other routers.
	After the BSR border is configured, the BSM information of Router A is displayed as follows:

```
switch#show ipv6 pim sparse-mode bsr-router

Candidate RP: 3000::5(Loopback 0)

Advertisement interval 60 seconds

Next Cand_RP_advertisement in 00:00:53
```

📌 **Configuring a PIM Router to Restrict the Source Address Range of BSMs to (8000::5/64)**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure PIM Router A to restrict BSMs. The restricted source address range is (8000::5/64).
	<pre>switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 8000::5/64 any switch(config-ipv6-acl)#exit switch(config)#ipv6 pim accept-crp list acl</pre>
<p>Verification</p>	<p>Before the BSM restriction is configured, the BSM information of Router A is displayed as follows:</p>
	<pre>switch#show ipv6 pim sparse-mode bsr-router PIMv2 Bootstrap information BSR address: 5000::5 Uptime: 00:05:42, BSR Priority: 64, Hash mask length: 126 Expires: 00:01:28 Role: Non-candidate BSR Priority: 0, Hash mask length: 126 State: Accept Preferred Candidate RP: 3000::5(Loopback 0) Advertisement interval 60 seconds Next Cand_RP_advertisement in 00:00:24 switch#</pre>
	<p>After the BSM restriction is configured, the BSM information of Router A is displayed as follows:</p>

```
switch#show ipv6 pim sparse-mode bsr-router

Candidate RP: 3000::5(Loopback 0)

Advertisement interval 60 seconds

Next Cand_RP_advertisement in 00:00:34
```

📌 **Configuring a C-BSR to Restrict the Source Address Range of C-PR Packets to (9000::5/64)**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure Router B to restrict C-RP packets. The restricted source address range is (9000::5/64).
	<pre>Nodexon(config)#ipv6 access-list acl Nodexon(config-ipv6-acl)#permit ipv6 9000::5/64 any Nodexon(config-ipv6-acl)#exit Nodexon(config)#ipv6 pim accept-crp list acl</pre>
<p>Verification</p>	<p>Before C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:</p>
	<pre>Nodexon#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2) Group(s): ff00::/8 RP: 3000::5(Not self) Info source: 3000::5, via bootstrap, priority 192 Uptime: 00:02:26, expires: 00:02:08 Nodexon#</pre>
	<p>After C-RP packet filtering is configured, information about all RP groups on Router B is displayed as follows:</p>
	<pre>Nodexon#show ipv6 pim sparse-mode rp mapping PIM Group-to-RP Mappings This system is the Bootstrap Router (v2)</pre>

📌 **Configuring the Static RP First**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address of Interface Loopback0 of Router A to 3000::5. (Omitted) ● Set the address of Interface Loopback1 of Router A to 4000::5. (Omitted) ● Set the static address of Router A to 3300::5. (Omitted) ● Set the static address of Router B to 3300::5. ● Configure the static RP first on Router A.
	<pre>switch(config)#ipv6 pim rp-address 3300::5 switch(config)#ipv6 pim static-rp-preferred</pre>
Verification	Before static RP first is configured, display information about the RP corresponding to FF16::1.
	<pre>switch#show ipv6 pim sparse-mode rp ff16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765 RP 3300::5, static (hash value 204800453 not used)</pre>
Verification	After static RP first is configured, display information about the RP corresponding to FF16::1.
	<pre>switch(config)#show ipv6 pim sparse-mode rp ff16::1 RP: 3300::5 (Static) PIMv2 STATIC RP PREFERRED PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765 RP 3300::5, static (hash value 204800453 not used) switch(config)#</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- No C-BSR is configured.

- The BSR border is not configured on an interface between different domains.

7.4.4 Configuring RP and DR Parameters

Configuration Effect

- Configure the ignorance of the C-RP priority for the RP reselection.
- Configure the DR at the data source end to detect the RP reachability.
- Restrict the (S,G) multicast group address of the data source so that the ASM model provides the multicast service only for multicast packets within the allowable range.
- Configure the rate limit for the DR at the data source end to transmit Register packets.
- Configure the checksum length of Register packets.
- Configure the source address of Register packets.
- Configure the suppression time of Register packets.
- Configure the probing time of NULL packets.
- Configure the TTL of Register packets received by the RP from the (S,G) multicast group address.
- Configure the static RP first.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

▾ **Configuring the Ignorance of the C-RP Priority for the RP Reselection**

- Optional.
- The ignorance of the C-RP priority can be enabled on each router unless otherwise specified.

▾ **Configuring the DR at the Data Source End to Detect the RP Reachability**

- Optional.
- The reachability detection can be enabled on the DR that is directly connected to the data source unless otherwise specified.

▾ **Restricting the (S,G) Address Range of Register Packets at the Data Source End**

- Optional.
- The (S,G) address range of Register packets at the data source end can be restricted on all routers that function as C-RPs or static RPs unless otherwise specified.

▾ **Restricting the Rate for the DR at the Data Source End to Transmit Register Packets**

- Optional.

- The transmission rate limit of Register packets can be enabled on the DR that is directly connected to the data source unless otherwise specified.

▾ Configuring the Checksum Length of Register Packets

- Optional.
- The checksum length of Register packets can be configured on all C-RPs or static RPs unless otherwise specified.

▾ Configuring the Source Address of Register Packets

- Optional.
- The source address of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

▾ Configuring the Suppression Time of Register Packets

- Optional.
- The suppression time of Register packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

▾ Configuring the Probing Time of NULL Packets

- Optional.
- The probing time of NULL packets can be configured on the DR that is directly connected to the data source unless otherwise specified.

▾ Configuring the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

- Optional.
- The TTL of Register packets from the (S,G) multicast group address can be configured on all routers that function as C-RPs or static RPs unless otherwise specified.

▾ Configuring the Static RP First

- Optional.
- The static RP first can be configured on all routers unless otherwise specified.

Verification

▾ Verifying the Ignorance of the C-RP Priority

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000::5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000::5 on Router B.

- Run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the RP that serves the current group.

▾ Verifying the DR at the Data Source End to Detect the RP Reachability

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000: : 5 on Router B. Configure the RP reachability detection on Router B.

- Run the **show running-config** command to check whether the RP reachability detection is configured.

↘ Verifying the Restriction of the (S,G) Address Range of Register Packets at the Data Source End

Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. Set the C-BSR address to 5000: : 5 on Router B. The address of the multicast group is FF16::2. Set Router A to receive packets only from the multicast source with the source address of (1300::1/64).

- Run the **show ip pim sparse-mode mroute** command to display the (S,G) entries.

↘ Verifying the Rate Limit for the DR at the Data Source End to Transmit Register Packets

- Set the rate of transmitting Register packets for Router B and then run the **show ip pim sparse-mode track** command to check the number of transmitted Register packets for confirmation.

↘ Verifying the Checksum Length of Register Packets

- Set Router A to check a Register packet based on the entire packet rather than based only on the packet header and Register packet header. Run the **show running-config** command to check the configuration.

↘ Verifying the Source Address of Register Packets

- Configure the source address of Register packets on Router B and run the **show running-config** command to check the configuration on Router A.

↘ Verifying the Suppression Time and Probing Time of Register Packets

- Configure the suppression time and probing time of Register packets on Router B and run the **show running-config** command to check the configuration.

↘ Verifying the TTL of Register Packets Received by the RP from the (S,G) Multicast Group Address

- Configure the TTL of Register packets from the (S,G) multicast group address on Router A and run the **show ip pim sparse-mode mroute** command to display the maximum (S,G) TTL.

↘ Verifying the Static RP First

- Configure a static RP and a C-RP on Router A, configure the static RP first, and then run the **show ipv6 pim sparse-mode rp ff16::2** command to display information about the current RP.

Related Commands

↘ Ignoring the C-RP Priority

Command	ipv6 pim ignore-rp-set-priority
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Displaying Information About the RP That Serves a Group

Command	show ipv6 pim sparse-mode rp-hash <i>group-address</i>
Parameter Description	<i>group-address</i> : Indicates the parsed group address.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

▾ Configuring the DR Directly Connected to the Data Source to Detect RP Reachability

Command	ipv6 pim register-rp-reachability
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the RP reachability is detected before Register packets are transmitted. If the RP is reachable, Register packets are transmitted. If the RP is unreachable, Register packets are not transmitted.

▾ Restricting the (S,G) Address Range of Register Packets at the Data Source End

Command	ipv6 pim accept-register { list <i>ipv6_access-list</i> [route-map <i>map-name</i>] route-map <i>map-name</i> [list <i>ipv6_access-list</i>] }
Parameter Description	list <i>ipv6_access-list</i> : References an IP extended ACL to restrict the (S,G) address range. The value range is 100-199, 2000-2699, and Word. route-map <i>map-name</i> : Uses a route map to restrict the (S,G) address range.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, when receiving a Register packet from an unauthorized source, the RP immediately returns the Register-Stop packet.

▾ Displaying Multicast Routing Entries

Command	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Parameter	<i>group-or-source-address</i> : Indicates the group address or source address. The two addresses cannot be

Description	group addresses or source addresses at the same time.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	A group address, a source address, or both addresses can be specified each time. You can also not specify a specific group address or source address but you cannot specify two group addresses or two source addresses at the same time.

▾ Configuring the Rate Limit for the DR to Transmit Register Packets

Command	ipv6 pim register-rate-limit <i>rate</i>
Parameter Description	<i>Rate</i> : Indicates the number of Register packets that are allowed to be transmitted per second. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the transmission rate of Register packets from the (S,G) multicast group address rather than the Register packets of the entire system. After this command is configured, the load of the source DR and RP will be relieved and Register packets whose rate does not exceed the limit will be transmitted.

▾ Displaying the Statistics on PIM Packets

Command	show ipv6 pim sparse-mode track
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	When the system is started, the statistics start time point is first set. Each time clear ip pim sparse-mode track is called, the statistics start time point is set again and the PIM packet counter is cleared.

▾ Configuring the Checksum Calculation of a Register Packet Based on the Entire Packet

Command	ipv6 pim register-checksum-wholepkt [group-list <i>ipv6_access-list</i>]
Parameter Description	group-list <i>access-list</i> : Uses an ACL to restrict the group addresses that use this configuration. <i>access-list</i> : Supports digits <1,99> and <1300,1999>. A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	The device calculates the checksum of a Register packet based on the entire PIM protocol packet including the encapsulated multicast data packet, rather than the PIM header of the Register packet. If group-list <i>ipv6_access-list</i> is not carried in this command, all group addresses apply this configuration.

▾ Configuring the Source Address of Register Packets

Command	ipv6 pim register-source { <i>ipv6_local_address</i> <i>interface-type interface-number</i> }
Parameter Description	<i>local_address</i> : Specifies an IPv6 address as the source address of Register packets. <i>interface-type interface-number</i> : Specifies the IPv6 address of an interface as the source address of Register packets.
Command Mode	Global configuration mode
Usage Guide	The configured address must be reachable. When the RP receives a Register packet, it transmits the Register-Stop packet with the source IPv6 address of the Register packet as the destination address. PIM-SMv6 does not need to be enabled on associated interfaces.

↘ Configuring the Suppression Time of Register Packets

Command	ipv6 pim register-suppression <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the suppression time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command Mode	Global configuration mode
Usage Guide	Configuring this value on the DR will change the suppression time of Register packets defined on the DR. If the ipv6 pim rp-register-kat command is not configured, configuring this value on the RP will change the keepalive time of the RP.

↘ Configuring the Probing Time of Register Packets

Command	ipv6 pim probe-interval <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the probing time of Register packets. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 5 .
Command Mode	Global configuration mode
Usage Guide	Probing time of Register packets is the interval for the source DR to transmit the NULL-Register packet to the RP prior to the timeout of the suppression time of Register packets. The probing time of Register packets cannot be larger than half of the suppression time of Register packets. Otherwise, the configuration fails and a warning is displayed. In addition, the suppression time of Register packets multiplied by three plus the probing time of Register packets cannot be larger than 65,535. Otherwise, a warning will be displayed.

↘ Configuring the KAT Interval on the RP

Command	ipv6 pim rp-register-kat <i>seconds</i>
Parameter Description	<i>Seconds</i> : Indicates the time of the KAT timer. The unit is seconds. The value ranges from 1 to 65,535 and the default value is 210 .

Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Configuring the Static RP First**

Command	ipv6 pim static-rp-preferred
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the priority of the static RP is higher than that of the RP elected by using the BSR mechanism.

Configuration Example

↘ **Configuring Whether the C-RP Priority Is Considered for the Group-to-RP Mapping**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set the address to 3000::5 and priority to 200 for Interface Loopback0 on Router A. (Omitted) ● Set the address to 4000: : 5 and priority to 56 for Interface Loopback1 on Router A. (Omitted) ● Set the C-BSR address to 5000: : 5 on Router B. (Omitted) ● Display the group corresponding to FF16::1. ● Configure the ignorance of C-RP priority on Router B.
	<pre>switch#configure terminal Nodexon(config)# ipv6 pim ignore-rp-set-priority</pre>
Verification	Before the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 4000::5 Info source: 5000::5, via bootstrap PIMv2 Hash Value 126 RP 4000::5, via bootstrap, priority 56, hash value 892666309 RP 3000::5, via bootstrap, priority 200, hash value 1161101765</pre>
	After the ignorance of the C-RP priority is configured, the following information is displayed:
	<pre>switch(config)#show ipv6 pim sparse-mode rp FF16::1 RP: 3000::5</pre>

```
Info source: 5000::5, via bootstrap
```

📌 **Configuring the Reachability Detection of the RP Directly Connected to the Data Source**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Configure the reachability detection of the RP directly connected to the data source.
	<code>Nodexon(config)#ipv6 pim register-rp-reachability</code>
Verification	Run the show running-config command to check the configuration. The following information is displayed:
	<pre>Nodexon(config)#show running-config ! ! ! ipv6 pim register-rp-reachability ipv6 pim bsr-candidate Loopback 0 ! !</pre>

📌 **Restricting the (S,G) Address Range of Register Packets at the Data Source End**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Set Router A to filter packets by source address and receive packets only from the source address (1300::1/64).
	<pre>switch(config)#ipv6 pim accept-register list acl % access-list 101 not exist switch(config)#ipv6 access-list acl switch(config-ipv6-acl)#permit ipv6 1300::1/64 any switch(config-ipv6-acl)#exit</pre>
Verification	Before the (S,G) address range of Register packets at the data source end is restricted, run the show ipv6 pim sparse-mode mroute command to display multicast entries. The (S,G) entry and (S,G,RPT) entry exist.
	<pre>switch#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.
- The (S,G) address range of Register packets at the data source end is not restricted or fails to be configured on a C-RP or static RP.
- When the (S,G) address range of Register packets at the data source end is restricted, the referenced ACL is not configured or the source/group address range allowed by the ACL is configured incorrectly.
- The source/group address ranges allowed by C-RPs or static RPs are inconsistent.

7.4.5 Configuring the Transmission Interval of Join/Prune Packets

Configuration Effect

- Change the transmission interval of Join/Prune packets to form an RPT or SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the transmission interval of Join/Prune packets.

Verification

Set the transmission interval of Join/Prune packets to 120 seconds on Router B. Run the **show ipv6 pim sparse-mode mroute** command to check the entry TTL.

Related Commands

↘ **Configuring the Transmission Interval of Join/Prune Packets**

Command	ipv6 pim jp-timer <i>seconds</i>
Parameter	<i>Seconds</i> : Indicates the transmission interval of Join/Prune packets.
Description	The unit is seconds. The value ranges from 1 to 65,535 and the default value is 60 .
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuration Example

Configuring the Transmission Interval of Join/Prune Packets on a Router

Configuration Steps	<ul style="list-style-type: none"> Configure basic functions of PIM-SMv6. (Omitted) Configure the transmission interval of Join/Prune packets on a router.
	<pre>Nodexon(config)#ip pim jp-timer 120</pre>
Verification	<p>Run the show ipv6 pim sparse-mode mroute command to check the entry. The transmission time of Join/Prune packets is not larger than 120.</p> <pre>switch(config)#show ipv6 pim sparse-mode mroute IPv6 Multicast Routing Table (*,*,RP) Entries: 0 (*,G) Entries: 1 (S,G) Entries: 1 (S,G,rpt) Entries: 1 FCR Entries: 0 REG Entries: 0 (*, ff16::1) RP: 4000::5 RPF nbr: :: RPF idx: None Upstream State: JOINED 00 01 02 03 04 05 06 07 08 09 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24 25 26 27 28 29 30 31 Local 0 . i 1 Joined 0</pre>

Common Errors

- The basic functions of PIM-SMv6 are not configured or fail to be configured.

7.4.6 Configuring the Last-Hop Device to Switch from the RPT to the SPT

Configuration Effect

- Switch the last-hop device from the RPT to the SPT.

Notes

- The basic functions of PIM-SMv6 must be configured.

Configuration Steps

- Configure the last-hop device to switch from the RPT to the SPT.

Verification

Configure basic functions of PIM-SMv6, make the DR at the data source end transmit data streams to Group FF16::1, and make the receiver forcibly join the Group FF16::1 to form a RPT. The DR at the receive end forcibly performs the switching from the RPT to SPT. Check the configuration on the RP.

Related Commands

▾ Enabling the SPT Switching Function

Command	<code>ipv6 pim spt-threshold [group-list <i>ipv6_access-list</i>]</code>
Parameter Description	group-list <i>ipv6_access-list</i> : References an IPv6 ACL to restrict the group address range that allows SPT switching. <i>ipv6_access-list</i> : A named ACL is supported.
Command Mode	Global configuration mode
Usage Guide	If group-list <i>ipv6_access-list</i> parameter is not carried in this command, all multicast groups are allowed to conduct SPT switching. If no is set in this command, group-list is carried, and the carried ACL is a configured ACL, the restriction of the ACL associated with group-list is cancelled and all groups are allowed to switch from the RPT to the SPT.

Configuration Example

▾ Configuring the Last-Hop Device to Switch from the RPT to the SPT

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic functions of PIM-SMv6. (Omitted) ● Make the DR at the data source end transmit code streams to Group FF16::1. ● Make the DR at the receive end receive code streams from Group FF16::1. ● Configure the last-hop device to switch from the RPT to the SPT on the DR at the receive end.
	<pre>switch(config)#ipv6 pim spt-threshold</pre>
Verification	Run the show running-config command to check the configuration.

```

switch(config)#show running-config
!
!
ip pim jp-timer 120
ip pim spt-threshold
ip pim rp-candidate Loopback 0
!
!

```

7.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears information about the dynamic RP.	clear ipv6 pim sparse-mode bsr rp-set *
Sets the packet statistics start time again and clears the PIMv6 packet counter.	clear ipv6 pim sparse-mode track

Displaying

Description	Command
Displays details about the BSR.	show ipv6 pim sparse-mode bsr-router
Displays the PIM-SM information about an interface.	show ipv6 pim sparse-mode interface [<i>interface-type interface-number</i>] [detail]
Displays the local MLD information about a PIM-SMv6 interface.	show ipv6 pim sparse-mode local-members [<i>interface-type interface-number</i>]
Displays the PIM-SMv6 routing information.	show ipv6 pim sparse-mode mroute [<i>group-or-source-address</i> [<i>group-or-source-address</i>]]
Displays the PIM-SMv6 neighbor information.	show ipv6 pim sparse-mode neighbor [detail]
Displays next hop-relevant information, including the next-hop interface ID, address, and metric.	show ipv6 pim sparse-mode nexthop

Displays all RPs configured on the local device and the groups served by the RPs.	show ipv6 pim sparse-mode rp mapping
Displays information about the RP that serves the group address.	show ipv6 pim sparse-mode rp-hash <i>ipv6-group-address</i>
Displays the number of PIM packets transmitted and received from the statistics start time to the current time.	show ipv6 pim sparse-mode track

8 Configuring IGMP Snooping

8.1 Overview

Internet Group Management Protocol (IGMP) snooping is a mechanism of listening to IP multicast. It is used to manage and control the forwarding of IP multicast traffic within VLANs, realizing Layer-2 multicasting.

As shown in the following figure, when a Layer-2 device is not running IGMP snooping, IP multicast packets are broadcasted within the VLAN; when the Layer-2 device is running IGMP snooping, IP multicast packets are transmitted only to profile members.

Figure 8-1 Networking Topology of IP Multicast Forwarding within the VLAN Before and After IGMP Snooping Is Run on the Layer-2 Device

Protocols and Standards

- RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

8.2 Applications

Application	Description
Layer-2 Multicast Control	Enables precise forwarding of Layer-2 multicast packets to avoid flooding at this layer.
Shared Multicast Services (Multicast VLAN)	Multiple users can share the multicast traffic of the same VLAN.
Premium Channels and Preview	Controls the range of multicast addresses that allow user demanding and allows preview for profiles who are inhibited from demanding.

8.2.1 Layer-2 Multicast Control

Scenario

As shown in the following figure, multicast packets are transmitted to users through a Layer-2 switch. When Layer-2 multicast control is not performed, namely, when IGMP snooping is not implemented, multicast packets are flooded to all the users including those who are not expected to receive these packets. After IGMP snooping is implemented, the multicast packets from an IP multicast profile will no longer be broadcast within the VLAN but transmitted to designated receivers.

Figure 8-2 Networking Topology of Implementing Layer-2 Multicast Control (Multicast VLAN)

Deployment

- Configure basic IGMP snooping functions.

8.2.2 Shared Multicast Services (Multicast VLAN)

Scenario

In Shared VLAN Group Learning (SVGL) mode or IVGL-SVGL mode (IVGL: Independent VLAN Group Learning), a device running IGMP snooping can provide shared multicast services (or multicast VLAN services) to the VLAN users. Typically, this function is used to provide the same video-on-demand (VOD) services to multiple VLAN users.

The following figure shows the operation of a Layer-2 multicast device in SVGL mode of IGMP snooping. The multicast router sends a multicast packet to VLAN 1, and the Layer-2 multicast device automatically transfers the packet to VLAN 1, VLAN 2, and VLAN 3. In this way, the multicast services of VLAN 1 are shared by VLAN 2 and VLAN 3.

Figure 8-3 Networking Topology of Shared Multicast Services (Multicast VLAN)

- i If the Layer-2 multicast device operates in IVGL mode, the router must send a packet to each VLAN, which wastes bandwidth and burdens the Layer-2 multicast device.

Deployment

- Configure basic IGMP snooping functions (in SVGL mode or IVGL-SVG mode).

8.2.3 Premium Channels and Preview

Scenario

In VOD application, by limiting the range of the multicast addresses that a user host can access, unpaid users will not be able to watch the premium channels. Thereafter, the preview service is offered to unpaid users before they decide whether to pay for it.

The users can preview a premium channel for a certain period of time (for example 1 minute) after demanding it.

Deployment

- Configure basic IGMP snooping functions (in any working mode).
- Configure the range of multicast addresses that a user can access.
- Enable the preview function for VOD profiles that are denied access.

8.3 Features

Basic Concepts

↳ Multicast Router Ports and Member Ports

i IGMP snooping is VLAN-based. The ports involved refer to the member ports within the VLAN.

The device running IGMP snooping identifies the ports within the VLAN as a multicast router port or member port so as to manage and control the forwarding of IP multicast traffic within the VLAN. As shown in the following figure, when IGMP snooping is run on a Layer-2 device, multicast traffic enters the multicast router port and exits from the member ports.

Figure 8-4 Networking Topology of Two IGMP Snooping Ports

- **Multicast router port:** The location of the multicast source is directed by the port on the Layer-2 multicast device which is connected to the multicast router (Layer-3 multicast device): By listening to IGMP packets, the Layer-2 multicast device can automatically detect the multicast router port and maintain the port dynamically. It also allows users to configure a static router port.
- **Member port:** The port is on a Layer-2 multicast device and is connected to member hosts. It directs the profile members. It is also called the Listener Port. By listening to IGMP packets, the Layer-2 multicast device can automatically detect the member port and maintain the port dynamically. It also allows users to configure a static member port.

Overview

Feature	Description
Listening to IGMP Packets	Discovers and identifies the router port and member port to establish and maintain the IGMP snooping forwarding entries. :
IGMP Snooping Working Modes	Provides independent or shared multicast services to the user VLAN.
Multicast Security Control	Controls the multicast service scope and load to prevent illegal multicast traffic.
Profile	Defines the range of multicast addresses that permit or deny user requests for reference of other functions.

Handling QinQ	Sets the forwarding mode of multicast packets on the QinQ interface.
IGMP Querier	On a network without a Layer-3 multicast device, the Layer-2 multicast device acts as an IGMP querier.

8.3.1 Listening to IGMP Packets

A device running IGMP snooping analyzes IGMP packets received, and finds and identifies the router port and member port using these packets, thereby creating and maintaining an IGMP snooping entry.

Working Principle

A device running IGMP snooping can identify and handle the following types of IGMP packets:

Query Packets

- An IGMP querier periodically sends General Query packets. When the IGMP querier receives Leave packets, it sends Group-Specific Query packets.

When the device running IGMP snooping receives the Query packets, it performs the following operations within the VLAN:

- Forward the IGMP Query packets to all the ports (except the receiving port of these packets).
- If the receiving port is a dynamic router port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- If the receiving port is not a dynamic router port, use it as a dynamic router port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- For general queries, reset the aging timer for all the dynamic member ports. If the timer expires, the port will no longer be used as the dynamic member port for the general group. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- For designated query packets, reset the aging timer for all the dynamic member ports of the designated profile. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile. By default, the maximum response time carried by the IGMP query packets is used as the timeout time of the aging timer. If **ip igmp snooping query-max-response-time** is run, the time displayed is used as the timeout time of the aging timer.
- If dynamic router port learning is disabled, IGMP snooping will not learn the dynamic router port.

Report Packets

- When a member host receives a query, it responds to the query with a Report packet. If a host requests to join a profile, it will also send a report.
- By default, IGMP Snooping is capable of processing IGMPv1 and IGMPv2 packets. For IGMPv3 Report packets, it processes profile information but does not process carried source information. IGMP Snooping v3 can be configured to process all information in IGMPv1, IGMPv2, and IGMPv3 packets.

When the device running IGMP snooping receives the Report packets, it performs the following operations within the VLAN:

- Forward the Report packets from all the router ports. After the **ip igmp snooping suppression enable** command is run in one IGMP query cycle, only the first report received by each profile will be forwarded.
- If the port on which Report packets are received is a dynamic member port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.
- If the port on which Report packets are received is not a dynamic member port, use it as a dynamic member port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.

↳ Leave Packets

- If a host requests to leave a profile, it will send a Leave packet.

When the device running IGMP snooping receives the Leave packets, it performs the following operations within the VLAN:

- Forward the leave packets from all the router ports.
- If the port on which leave packets are received is a dynamic member port and the Leave function is enabled, the port will be immediately deleted from the IGMP snooping forwarding entry of the designated profile and will no longer be used as the dynamic member port.
- If the port on which the leave packets are received is a dynamic member port and the Leave function is disabled, the port state should be maintained.

Related Configuration

↳ Configuring a Static Router Port

Run the **ip igmp snooping vlan mrouter interface** command to configure a static router port.

↳ Configuring a Static Member Port

Run the **ip igmp snooping vlan static interface** command to configure a static member port.

↳ Enabling Report Suppression

Report suppression is disabled by default.

Run the **ip igmp snooping suppression enable** command to enable report suppression.

After report suppression is enabled, in one IGMP query cycle, only the first Report packet received by each profile will be forwarded. The source media access control (MAC) address of the forwarded report will be changed to the MAC address of the device.

↳ Enabling Immediate Leave

Immediate leave is disabled by default.

Run the **ip igmp snooping fast-leave enable** command to enable immediate leave.

↳ Enabling Dynamic Router Port Learning

Dynamic router port learning is enabled by default.

Run the **no ip igmp snooping mrouter learn pim-dvmrp** command to disable dynamic router port learning.

Run the **no ip igmp snooping vlan vid mrouter learn pim-dvmrp** command to disable dynamic router port learning for designated VLANs.

📌 Configuring the Aging Time of a Dynamic Router Port

The default aging time is 300s.

When a dynamic router port receives a query packet, the aging timer of the port is enabled or reset; if the aging time is not configured, the maximum response time carried by the query packet is used as the aging time.

Run **ip igmp snooping dyn-mr-aging-time** to configure the aging time of the dynamic router port.

📌 Configuring the Aging Time of a Dynamic Member Port

The default aging time is 260s.

When a dynamic member port receives a query packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time carried by the query packet.

When a dynamic member port receives a Report packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time of the dynamic member port.

Run **ip igmp snooping host-aging-time** to configure the aging time of the dynamic member port.

📌 Configuring the Maximum Response Time of a Query Packet

The maximum response time of a query packet is not configured by default and the maximum response time carries by the query packet is used.

Run **ip igmp snooping query-max-response-time** to configure the maximum response time of a query packet.

8.3.2 IGMP Snooping Working Modes

A device running in the three modes (IVGL, SVGL, and IVGL-SVGL) of IGMP snooping can provide independent multicast services or shared multicast services to the user VLAN.

Working Principle

📌 IVGL

In IVGL mode, a device running IGMP snooping can provide independent multicast services to each user VLAN.

Independent multicast services indicate that multicast traffic can be forwarded only within the VLAN it belongs to, and a user host can subscribe to the multicast traffic within the VLAN that the host belongs to.

📌 SVGL

In SVGL mode, a device running IGMP snooping can provide shared multicast services to the user VLAN.

Shared multicast services can be provided only on shared VLANs and sub VLANs and SVGL multicast addresses are used. In a shared VLAN, the multicast traffic within the range of SVGL multicast addresses is forwarded to a sub VLAN, and the user hosts within the sub VLAN subscribe to such multicast traffic from the shared VLAN.

- In a shared VLAN and sub VLAN, shared multicast services will be provided to the multicast traffic within the range of SVGL multicast addresses. Other multicast traffic will be discarded.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

i When the user VLAN is set to a shared VLAN or sub VLAN, shared multicast services are provided; when a user VLAN is set to other VLANs, independent multicast services are provided.

IVGL-SVGL

IVGL-SVGL mode is also called the hybrid mode. In this mode, a device running IGMP snooping can provide both shared and independent multicast services to the user VLAN.

- In a shared VLAN and sub VLAN, multicast services will be provided to the multicast traffic within an SVGL profile. For other multicast traffic, independent multicast services will be provided.
- Other VLANs (except shared VLANs and sub VLANs) apply to independent multicast services.

i When a user VLAN is configured as a shared VLAN or sub VLAN, both public multicast services and independent multicast services are available. When a user VLAN is configured as a VLAN other than shared VLAN and sub VLAN, only the independent multicast services are available.

Related Configuration

Enabling IGMP Snooping and Selecting a Working Mode

IGMP snooping is disabled by default.

Run the **ip igmp snooping ivgl** command to enable IGMP snooping in IVGL mode.

Run the **ip igmp snooping svgl** command to enable IGMP snooping in SVGL mode.

Run the **ip igmp snooping ivgl-svgl** command to enable IGMP snooping in IVGL-SVGL mode.

A working mode must be designated when enabling IGMP snooping, namely, one of the preceding working modes must be selected.

Configuring Shared VLAN

The shared VLAN is VLAN 1 by default.

Run the **ip igmp snooping svgl vlan** command to designate a VLAN as the shared VLAN.

In SVGL mode and IVGL-SVGL mode, only one VLAN can be configured as the shared VLAN.

Configuring Sub VLAN

By default, a sub VLAN is any VLAN except the shared VLAN.

Run the **ip igmp snooping svgl subvlan** command to designate a VLAN as the sub VLAN.

In SVGL mode and IVGL-SVGL mode, the number of sub VLANs is not limited.

↘ Configuring an SVGL Profile

No default setting.

Run the **ip igmp snooping svgl profile** *profile_num* command to configure the address range of an SVGL profile.

 In SVGL mode and IVGL-SVGL mode, the SVGL profile range must be configured; otherwise, shared multicast services cannot be provided.

8.3.3 IGMP Security Control

A device running IGMP snooping can control the multicast service scope and load, and effectively prevents illegal multicast traffic.

Working Principle

↘ Configuring the Profile Filtering for User Demanding

By configuring the profile list that a user can access, you can customize the multicast service scope to guarantee the interest of operators and prevent illegal multicast traffic.

To enable this function, you should use a profile to define the range of multicast addresses that a user is allowed to access.

- When the profile is applied on a VLAN, you can define the multicast addresses that a user is allowed to access within the VLAN.
- When the profile is applied on an interface, you can define the multicast addresses that a user is allowed to access under the port.

↘ Multicast Preview

If the service provider wants to allow the users to preview some multicast video traffic that denies the users' access, and stop the multicast video traffic after the preview duration is reached, the user-based multicast preview function should be provided. The multicast preview function is used together with multicast permission control. For example, in the application of videos, the administrator controls some premium channels by running the **ip igmp profile** command on a port or VLAN. In this way, unsubscribed users will not be able to watch these channels on demand. If users want to preview the channels before they decide whether to pay for watching or not, the multicast preview function can be enabled, allowing the premium channels to be previewed by unpaid users for a certain period of time (for example 1 minute).

↘ Controlling the Maximum Number of Profiles Allowed for Concurrent Request

If there is too much multicast traffic requested at the same time, the device will be severely burdened. Configuring the maximum number of profiles allowed for concurrent request can guarantee the bandwidth.

- You can limit the number of profiles allowed for concurrent request globally.
- You can also limit the number of profiles allowed for concurrent request on a port.

↘ Controlling the Entry of Multicast Traffic

By running the **ip igmp snooping source-check port** command to enable source port inspection, you can restrict the entry of multicast traffic to prevent illegal traffic.

- When source port inspection is enabled, only the multicast traffic entered from the router port is considered as legal; the traffic from other ports is considered as illegal and will be discarded.
- When source port inspection is disabled, the traffic entered from any port is considered as legal.

↘ **Configuring the Source IP Inspection for Multicast Traffic**

By enabling source IP inspection, you can restrict the IP address of multicast traffic to prevent illegal traffic.

Source IP inspection includes the inspection of the source IP addresses of specific profiles and of default profiles.

- Inspection of the source IP addresses of default profiles (also called source-check default-server): Specifies the source IP addresses for all the multicast profiles within all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- Inspection of the source IP addresses of specific profiles (also called limit-ipmc): Specifies the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Related Configuration

↘ **Configuring the Profile Filtering**

By default, profiles are not filtered and allow user access.

To filter multicast profiles, run the **ip igmp snooping filter** command in interface configuration mode or global configuration mode.

↘ **Enabling Preview**

Preview is not enabled by default.

Run the **ip igmp snooping preview** command to enable preview and restrict the range of the profiles permitted for multicast preview.

Run the **ip igmp snooping preview interval** to set the multicast preview duration.

↘ **Configuring the Maximum Number of Profiles Allowed for Concurrent Request on a Port**

By default, the number of profiles allowed for concurrent request is not limited.

Run the **ip igmp snooping max-groups** command to configure the maximum number of profiles allowed for concurrent request.

↘ **Configuring the Maximum Number of Multicast Profiles Allowed Globally**

By default, the maximum number of multicast profiles allowed globally is 65,536.

Run the **ip igmp snooping l2-entry-limit** command to configure the maximum number of multicast profiles allowed globally.

↘ **Enabling Source Port Inspection**

By default, source port inspection is not configured.

Run the **ip igmp snooping source-check port** command to enable source port inspection.

↳ Enabling Source IP Inspection

By default, source IP inspection is disabled.

- Run the **ip igmp snooping source-check default-server** *address* command to enable source IP inspection and specify the default source IP address (applicable to any profile of any VLAN).
- (Optional) Run the **ip igmp snooping limit-ipmc vlan** *vid address group-address server source-address* command to specify a specific source IP address for a specific profile of specific VLAN (applicable to a specific profile of specific VLAN).

First, you must enable source IP inspection to specify default source address, and then a specific source address can be specified for a specific profile of specific VLAN. If a source address is specified for a specific profile of specific VLAN, the multicast traffic of the specific profile will perform inspection for the source address specified by this command. Other multicast traffic will perform inspection for default source addresses.

8.3.4 IGMP Profile

A multicast profile is used to define the range of multicast addresses that permit or deny user demanding request for reference of other functions.

Working Principle

The profile is used to define the range of multicast addresses.

When SVGL mode is enabled, an SVGL profile is used to define the range of SVGL multicast addresses.

When the multicast filter is configured on an interface, a profile is used to define the range of multicast addresses that permit or deny user request under the interface.

When a VLAN filter is configured, a profile is used to define the range of multicast addresses that permit or deny user request under within the VLAN.

When the preview function is enabled, a profile is used to define the range of multicast address allowed for preview.

Related Configuration

↳ Configuring a Profile

Default configuration:

- Create a profile, which is **deny** by default.

Configuration steps:

- Run the **ip igmp profile** *profile-number* command to create a profile.
- Run the **range** *low-address high-address* command to define the range of multicast addresses. Multiple address ranges are configured for each profile.

- (Optional) Run the **permit** or **deny** command to permit or deny user request (**deny** by default). Only one **permit** or **deny** command can be configured for each profile.

8.3.5 IGMP QinQ

Working Principle

On a device with IGMP snooping enabled and dot1q-tunnel (QinQ) port configured, IGMP snooping will handle the IGMP packets received by the QinQ port using the following two approaches:

- Approach 1: Create a multicast entry on the VLAN where IGMP packets are located. The forwarding of IGMP packets on the VLAN where these packets are located is called transparent transmission. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 10 and forwards the multicast Query packet to the router port of VLAN 10.
- Approach 2: Create a multicast entry on the default VLAN of the QinQ port. Encapsulate the multicast packet with the VLAN tag of the default VLAN where the QinQ port is located and forward the packet within the default VLAN. For example, presume that IGMP snooping is enabled for a device, Port A is designated as the QinQ port, the default VLAN of this port is VLAN 1, and it allows the passage of VLAN 1 and VLAN 10 packets. When a multicast Query packet is sent by VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 1, encapsulates the multicast query packet with the tag of VLAN 1, and forward the packet to VLAN 1 router port.

Related Configuration

📄 [Configuring QinQ](#)

By default, IGMP snooping works in the mode specified in Approach 2.

Run the **ip igmp snooping tunnel** command to implement Approach 1.

8.3.6 IGMP Querier

On a network with a Layer-3 multicast device, the Layer-3 multicast device acts as an IGMP querier. In this case, a Layer-2 device needs only to listen to IGMP packets to establish and maintain the forwarding entry, realizing Layer-2 multicast.

On a network without a Layer-3 multicast device, the Layer-2 multicast device must be configured with the IGMP querier function so that the device can listen to IGMP packets. In this case, a Layer-2 device needs to act as an IGMP querier as well as listen to IGMP packets to establish and maintain the forwarding entry to realize Layer-2 multicast.

Working Principle

A Layer-2 device acts as an IGMP querier to periodically send IGMP Query packets, listen to and maintain the IGMP Report packets replied by a user, and create a Layer-2 multicast forwarding entry. You can adjust relevant parameters of the Query packets sent by the IGMP querier through configuration.

When the device receives a Protocol-Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP) packet, it considers that a multicast router, which will act as an IGMP querier, exists on the network and disables the querier function. In this way, IGMP routing will not be affected.

When the device receives the IGMP Query packets from other devices, it will compete with other devices for the IGMP querier.

↳ Enabling the Querier Function

You can enable the querier for a specific VLAN or all VLANs.

Only when the global querier function is enabled can the queriers for specific VLANs take effect.

↳ Specifying the IGMP Version for a Querier

The version of IGMP used for sending Query packets can be configured as IGMPv1, IGMPv2, or IGMPv3.

↳ Configuring the Source IP Address of a Querier

You can configure the source IP address of a query packet sent by the querier based on VLANs.

When the source IP address of the querier is not configured, the querier will not take effect.

↳ Configuring the Query Interval of a Querier

You can configure the intervals for sending global Query packets based on different queriers on different VLANs.

↳ Configuring the Maximum Response Time of a Query Packet

You can configure the maximum response time carried by a Query packet that is sent by a querier. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1. You can configure different maximum response time for queriers on different VLANs.

↳ Configuring the Aging Time of a Querier

When other IGMP queriers exist on a network, the existing device will compete with other queriers. If the existing device fails to be elected and is in the non-querier state, the aging timer of a querier will be enabled. After the timer expires, other queriers on the network are considered as expired and the existing device will be resumed as the querier.

Related Configuration

↳ Enabling the Querier Function

By default, the querier function of a device is disabled.

Run the **ip igmp snooping querier** command to enable the global querier function.

Run the **ip igmp snooping vlan num querier** command to enable the querier function for specific VLANs.

↳ Specifying the IGMP Version for a Querier

By default, a querier runs IGMPv2.

Run the **ip igmp snooping querier version** command to configure the global querier version.

Run the **ip igmp snooping vlan querier version** command to specify the querier version for specific VLANs.

↘ **Configuring the Source IP Address of a Querier**

By default, the source IP address of a querier is 0.

Run the **ip igmp snooping querier address** command to enable global source IP addresses of queriers.

Run the **ip igmp snooping vlan querier address** command to specify the source IP addresses of the queriers on specific VLANs.

↘ **Configuring the Query Interval of a Querier**

By default, the query interval of a querier is 60s.

Run the **ip igmp snooping querier query-interval** command to enable the global query interval of queriers.

Run **ip igmp snooping vlan querier query-interval** to specify the global query interval of the queriers on specific VLANs.

↘ **Configuring the Maximum Response Time of a Query Packet**

By default, the maximum response time of a query packet is 10s.

Run the **ip igmp snooping querier max-response-time** command to configure the maximum response time of the query packets sent by global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to specify the maximum response time of the query packets sent by the queriers on specific VLANs.

↘ **Configuring the Aging Time of a Querier**

By default, the aging time of a querier is 125s.

Run the **ip igmp snooping querier max-response-time** command to configure the aging time of global queriers.

Run the **ip igmp snooping vlan querier max-response-time** command to configure the aging time of queriers on specific VLANs.

8.4 Configuration

Configuration	Description and Command
Configuring Basic IGMP Snooping Functions (IVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected.
	ip igmp snooping ivgl Enables global IGMP snooping in IVGL mode.
	no ip igmp snooping vlan <i>num</i> Disables IGMP snooping for a VLAN.
Configuring Basic IGMP Snooping Functions (SVGL Mode)	 Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in SVGL mode.

<p>Mode</p>	<p>ip igmp snooping svgl</p>	<p>Enables global IGMP snooping in IVGL mode.</p>
	<p>no ip igmp snooping vlan <i>num</i></p>	<p>Disables IGMP snooping for a VLAN.</p>
	<p>ip igmp snooping svgl profile <i>profile_num</i></p>	<p>Configures the SVGL profile.</p>
	<p>ip igmp snooping svgl vlan</p>	<p>Specifies the SVGL shared VLAN.</p>
	<p>ip igmp snooping svgl subvlan</p>	<p>Specifies the SVGL sub VLAN.</p>
<p>Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)</p>	<p> Any of IVGL mode, SVGL mode, and IVGL-SVGL mode must be selected. It is used to enable IGMP snooping in IVGL-SVGL mode.</p>

	<p>ip igmp snooping query-max-response-time <i>time</i></p>	<p>Configures the maximum response time of an IGMP query packet.</p>
	<p>ip igmp snooping suppression enable</p>	<p>Enables IGMP Report packet suppression.</p>
<p>Configuring IGMP Security Control</p>	<p> (Optional) It used to guarantee the security when a user requests a multicast profile.</p>	
	<p>ip igmp snooping filter <i>profile-number</i></p>	<p>Configures the profile filtering for user access.</p>

	ip igmp snooping vlan num filter <i>profile-number</i>	Configures the per-VLAN profile filtering for user access.
	ip igmp snooping l2-entry-limit <i>number</i>	Configures the maximum number of profiles globally for user access.
	ip igmp snooping max-groups <i>number</i>	Configures the maximum number of dynamic profiles for user access.
	ip igmp snooping source-check port	Enables source IP inspection, which ensures the multicast traffic from the router port is legal.
	ip igmp snooping source-check default-server <i>address</i>	Enables source IP inspection. The multicast traffic whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping limit-ipmc vlan vid address <i>group-address server source-address</i>	Specifies a VLAN. In the multicast traffic of multicast addresses, the one whose source IP address matches the specified source IP address is considered as legal traffic.
	ip igmp snooping preview <i>profile-number</i>	Enables the preview function for a specified profile.
	ip igmp snooping preview interval <i>num</i>	Configures the preview duration.
Configuring an IGMP Profile	 (Optional) It is used to define the range of multicast addresses that permits or denies the access of a user host.	
	ip igmp profile <i>profile-number</i>	Creates a profile.
	range <i>low-address high_address</i>	Configures the profile range.
	permit	Permits the access of a user host.
	deny	Denies the access of a user host.
Configuring IGMP QinQ	 (Optional) It is used to configure QinQ interface to forward multicast packets using the VLAN identifier (VID) carried by packets.	
	ip igmp snooping tunnel	Configures QinQ to transmit IGMP packets transparently.
Configuring an IGMP Querier	 (Optional) It is used to enable IGMP querier function on a network without a Layer-3 multicast device.	
	ip igmp snooping querier	Enables global querier function.
	ip igmp snooping vlan num querier	Enables the querier for a VLAN.

ip igmp snooping querier version <i>num</i>	Specifies the IGMP version for queriers globally.
ip igmp snooping vlan <i>num</i> querier version <i>num</i>	Specifies the IGMP version for a querier of a VLAN.
ip igmp snooping querier address a.b.c.d	Configures the source IP address of queriers globally.
ip igmp snooping vlan <i>num</i> querier address a.b.c.d	Configures the source IP address for a querier of a VLAN.
ip igmp snooping querier query-interval <i>num</i>	Configures the query interval of queriers globally.
ip igmp snooping vlan <i>num</i> querier query-interval <i>num</i>	Configures the query interval for a querier of a VLAN.
ip igmp snooping querier max-response-time <i>num</i>	Configures the maximum response time for query packets globally.
ip igmp snooping vlan <i>num</i> querier max-response-time <i>num</i>	Configures the maximum response time of query packets for a VLAN.
ip igmp snooping querier timer expiry <i>num</i>	Configures the aging timer for queriers globally.
ip igmp snooping vlan <i>num</i> querier timer expiry <i>num</i>	Configures the aging timer for a querier of a VLAN.

8.4.1 Configuring Basic IGMP Snooping Functions (IVGL Mode)

Configuration Effect

- Enable IGMP snooping to realize Layer-2 multicast.
- Provide independent multicast services to each VLAN.

Notes

- IP multicast cannot be realized in SVGL mode. If IP multicast must be used, select the IVGL mode.

Configuration Steps

📌 Enabling Global IGMP Snooping in IVGL Mode

Mandatory.

After IGMP snooping is enabled globally, this function will be enabled for all VLANs.

If not specified, it is advised to run global IGMP snooping on all the devices connected user hosts.

📌 Disabling IGMP Snooping for a VLAN

(Optional) You can use this function if you wish to disable IGMP snooping on specified VLANs.

Only when global IGMP snooping is enabled can it be disabled on specified VLANs.

In IVGL mode, each VLAN can enjoy independent multicast services. Disabling any VLAN multicast services will not interfere in the services provided to the others.

Verification

- Run the **show ip igmp snooping gda-table** command to display the IGMP snooping forwarding table and verify that the member ports include only those connecting member hosts.
- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL mode.

Related Commands

↘ Enabling Global IGMP Snooping in IVGL Mode

Command	ip igmp snooping ivgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is executed, IGMP snooping will be run on all VLANs. By default, IGMP snooping is disabled.

↘ Disabling IGMP Snooping for a VLAN

Command	no ip igmp snooping vlan <i>num</i>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Only when global IGMP snooping is enabled can it be disabled on specified VLANs. In IVGL mode, you can disable IGMP snooping on any VLAN.

↘ Displaying the IGMP Snooping Entry

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	This command is used to verify that the ports include only those connecting member hosts.

↘ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in IVGL mode, the following information is displayed: <div style="background-color: #f0f0f0; padding: 5px; margin-top: 5px;">IGMP Snooping running mode: IVGL</div>

Configuration Example

▾ Providing Layer-2 Multicast Services for the Subnet Hosts

<p>Scenario</p> <p>Figure 8-5</p>	
	<p>A is the multicast router and is connected directly to the multicast source.</p> <p>B is the Layer-2 device and is connected directly to the user host.</p> <p>Receiver 1, Receiver 2, and Receiver 3 belong to VLAN 1.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit</pre>

	<pre>A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)# ip igmp snooping ivgl</pre>
Verification	<p>Send packets from the source (10.1.1.1) to G (229.1.1.1) to add Receiver 1 to G.</p> <ul style="list-style-type: none"> ● Confirm that the packets (10.1.1.1 and 229.1.1.1) are received by Receiver 1. ● Display the IGMP snooping forwarding entry on B and ensure that the port (10.1.1.1, 229.1.1.1, 1) includes only Fa0/2. ● Check whether the IGMP snooping working mode is IVGL.
B	<pre>B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 2 OPORTS: FastEthernet 0/1(M) FastEthernet 0/2(D) B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Global Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds)</pre>

```
Dynamic Host Aging Time : 260(Seconds)

vlan 1
-----

IGMP Snooping state: Enable
Multicast router learning mode: pim-dvmrp
IGMP Fast-Leave: Disabled
IGMP VLAN querier: Disable
IGMP VLAN Mode: STATIC
```

Common Errors

- The working mode of IGMP snooping is improper.

8.4.2 Configuring Basic IGMP Snooping Functions (SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select SVGL mode to realize Layer-2 multicast.
- Share the VLAN multicast services.

Configuration Steps

▾ Enabling Global IGMP Snooping in SVGL Mode

Mandatory.

Enable global IGMP snooping in SVGL mode.

Configure the range of associated SVGL profiles.

▾ Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

▾ Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the `show ip igmp snooping` command to display the basic IGMP snooping information and verify that IGMP snooping is working in SVGL mode.
- Run the `show ip igmp snooping gda-table` command to check whether inter-VLAN multicast entries are properly formed.

Related Commands

↳ Enabling Global IGMP Snooping in SVGL Mode

Command	<code>ip igmp snooping svgl</code>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the SVGL mode is selected, the range of profiles within SVGL multicast addresses needs to be associated.

↳ Configuring the SVGL profile

Command	<code>ip igmp snooping svgl profile <i>profile_num</i></code>
Parameter Description	<i>profile_num</i> : Configures SVGL to associate a profile.
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

↳ Specifying the SVGL Shared VLAN

Command	<code>ip igmp snooping svgl vlan <i>vid</i></code>
Parameter Description	<i>vid</i> : Indicates a VLAN.
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

↳ Specifying the SVGL Sub VLAN

Command	<code>ip igmp snooping svgl subvlan <i>vid-range</i></code>
Parameter Description	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Command Mode	Interface configuration mode
Usage Guide	By default, all the VLANs except the shared VLAN are used as sub VLANs.

↳ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in SVGL mode, the following information is displayed: <div style="background-color: #f0f0f0; padding: 5px; margin-top: 5px;">IGMP Snooping running mode: SVGL</div>

Configuration Example

Enabling SVGL on the Access Device

<p>Scenario</p> <p>Figure 8-6</p>	
	<p>A is the multicast router and is connected directly to the multicast source.</p> <p>B is the Layer-2 device and is connected directly to the user host.</p> <p>Receiver 1 is connected to VLAN 2, Receiver 2 is connected to VLAN 3, and Receiver 3 is connected to VLAN 4.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select SVGL mode. ● Configure the range of associated SVGL multicast addresses on B.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit</pre>

	<pre>A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range 224.1.1.1 238.1.1.1 B(config-profile)#exit B(config)#ip igmp snooping svgl B(config)#ip igmp snooping svgl profile 1</pre>
Verification	<p>Send packets from the source (10.1.1.1) to G (229.1.1.1) and add Receiver 1, Receiver 2 and Receiver 3 to G.</p> <ul style="list-style-type: none"> ● Confirm that the packets (10.1.1.1 and 224.1.1.1) are received by Receiver 1, Receiver 2, and Receiver 3. ● Display the IGMP snooping forwarding entry on B and ensure that the ports (*, 224.1.1.1, 1) include Gi0/2, Gi0/3, and Gi0/4. ● Check whether the IGMP snooping working mode is SVGL.
B	<pre>B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(2) 1 OPORTS: GigabitEthernet 0/2(D) VLAN(3) 1 OPORTS: GigabitEthernet 0/3(D) VLAN(4) 1 OPORTS: GigabitEthernet 0/4(D) B# show ip igmp snooping IGMP Snooping running mode: SVGL</pre>

```

IGMP Snooping L2-entry-limit: 65536

SVGL vlan: 1

SVGL profile number: 1

Source port check: Disable

Source ip check: Disable

IGMP Preview: Disable

IGMP Tunnel: Disable

IGMP Preview group aging time : 60(Seconds)

Dynamic Mroute Aging Time : 300(Seconds)

Dynamic Host Aging Time : 260(Seconds)

```

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.

8.4.3 Configuring Basic IGMP Snooping Functions (IVGL-SVGL Mode)

Configuration Effect

- Enable IGMP snooping and select IVGL-SVGL mode to realize Layer-2 multicast.
- The SVGL profiles can share the multicast services.
- The non-SVGL profiles run in IVGL mode.

Configuration Steps

📌 Enabling Global IGMP Snooping in IVGL-SVGL Mode

Mandatory.

Enable global IGMP snooping in IVGL-SVGL mode.

Configure the range of associated SVGL profiles.

📌 Specifying the SVGL Shared VLAN

(Optional) By default, VLAN 1 is used as the shared VLAN. You can adjust this configuration for other options.

📌 Specifying the SVGL Sub VLAN

(Optional) By default, all the VLANs are used as the sub VLANs of SVGL and can share the multicast services of the shared VLAN. You can adjust this configuration for other options.

Verification

- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL-SVGL mode.
- Run the **show ip igmp snooping gda-table** command to check whether inter-VLAN multicast entries are properly formed for the SVGL profiles.
- Run the **show ip igmp snooping gda-table** command to check whether intra-VLAN multicast entries are properly formed for the SVGL profiles.

Related Commands

↳ Enabling Global IGMP Snooping in IVGL-SVGL Mode

Command	ip igmp snooping ivgl-svgl
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, IGMP snooping is disabled. After the IVGL-SVGL mode is selected, the SVGL profiles needs to be associated.

↳ Configuring the SVGL Profile

Command	ip igmp snooping svgl profile <i>profile_num</i>
Parameter Description	<i>profile_num</i> : Configures SVGL to associate a profile.
Command Mode	Global configuration mode
Usage Guide	By default, no profile is associated with SVGL.

↳ Specifying the SVGL Shared VLAN

Command	ip igmp snooping svgl vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates a VLAN.
Command Mode	Interface configuration mode
Usage Guide	By default, VLAN 1 is used as the shared VLAN.

↳ Specifying the SVGL Sub VLAN

Command	ip igmp snooping svgl subvlan <i>vid-range</i>
Parameter Description	<i>vid-range</i> : Indicates VLAN ID or the range of VLAN IDs.
Command Mode	Interface configuration mode
Usage Guide	By default, all the VLANs except the shared VLAN are used as sub VLANs.

▾ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in SVGL mode, the following information is displayed: <pre>IGMP Snooping running mode: SVGL</pre>

▾ Displaying the IGMP Snooping Working Mode

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Common Errors

- The SVGL profile is not configured.
- The sent multicast traffic is not within the SVGL profile.
- The IVGL multicast traffic cannot be forwarded within the SVGL profile.

8.4.4 Configuring the Packet Processing

Configuration Effect

- Configure specified ports as the static router ports to receive the multicast traffic from all profiles.
- Configure specified ports as the static member ports to receive the multicast traffic from specified profiles
- Enable Report packets suppression to forward only the first Report packet from a specified VLAN or profile to the router port within a query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.
- Configure the immediate-leave function to delete a port from the entry of member ports when a leave packet is received by the port.
- Disable dynamic router port learning to disable the learning of any router port.
- Based on network load and configuration of a multicast device, you can adjust the aging time of a router port and member port as well as the maximum response time of a query packet.

Notes

- Only when basic IGMP snooping is configured can relevant configurations take effect.

Configuration Steps

↘ **Configuring a Static Router Port**

- Optional.
- You can perform this configuration if you want to specify a static port to receive all the multicast traffic within the VLAN.

↘ **Configuring a Static Member Port**

- Optional.
- You can perform this configuration if you want to specify a static port to receive specific multicast traffic within the VLAN.

↘ **Enabling Report Packet Suppression**

- Optional.
- When there are numerous receivers to receive the packets from the same multicast profile, you can enable Report packets suppression to suppress the number of Report packets to be sent.

↘ **Enabling the Immediate-Leave Function**

- Optional.
- When there is only one receiver on a port, you can enable Leave to speed up the convergence of protocol upon leave.

↘ **Disabling Dynamic Router Port Learning**

- Optional.
- This function is used when multicast traffic needs to be forwarded only within the Layer-2 topology but not to a Layer-3 router.

↘ **Configuring the Aging Time of a Dynamic Router Port**

- Optional.
- You can configure the aging time based on network load.

↘ **Configuring the Aging Time of a Dynamic Member Port**

- Optional.
- You can configure the aging time based on the interval for sending IGMP query packets by the connected multicast router. Typically, the aging time is calculated as follows: Interval for sending IGMP query packets x 2 + Maximum response time of IGMP packets

↘ **Configuring the Maximum Response Time of a Query Packet**

- Optional.
- You can configure the aging time based on network load.

Verification

- Run the **show ip igmp snooping mrouter** command to check whether the configured static router port has an "S" in the displayed configuration information.
- Run the **show ip igmp snooping gda** command to check whether the configured static member port is marked with an S.
- Run the **show ip igmp snooping** command to check whether Report packets suppression, immediate leave, router port learning, router port aging time, member port aging time, and the maximum response time of the Query packet take effect.

Related Commands

▾ Configuring a Static Router Port

Command	ip igmp snooping vlan <i>vid</i> mrouter interface <i>interface-type interface-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	In SVGL mode, if a sub VLAN is not configured, only the configurations for the static router port within the shared VLAN can take effect, and the others can be configured but cannot take effect. If a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL-SVGL mode, if a sub VLAN is not configured, the configurations for the static router ports within all the VLANs can take effect; if a sub VLAN is configured, only the configurations for the static router port within the shared VLAN or a non-sub VLAN can take effect, and the others can be configured but cannot take effect. In IVGL mode, the configurations for the static router ports within all the VLANs can take effect.

▾ Configuring a Static Member Port

Command	ip igmp snooping vlan <i>vid</i> static <i>group-address</i> interface <i>interface-type interface-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>group-address</i> : Indicates a profile address. <i>interface-type interface-number</i> : Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	By default, no static member port is configured.

▾ Enabling Report Packet Suppression

Command	ip igmp snooping suppression enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>When Report packets suppression is enabled, only the first Report packet from a specified VLAN or profile is forwarded to the router port within a Query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.</p> <p>Only the IGMPv1 and IGMPv2 Report packets can be suppressed, and the IGMPv3 Report packets cannot be suppressed.</p>

▾ Enabling the Immediate-Leave Function

Command	ip igmp snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>When this function is enabled, a port will be deleted from the entry of the member port when the port receives a leave packet. After that, the packets will no longer be forwarded to this port when it receives the query packets of specified profiles. Leave packets include the IGMPv2 Leave packets as well as the IGMPv3 Report packets that include types but carry no source address.</p> <p>The immediate-leave function applies only to the scenario where only one host is connected to a device port. It is used to conserve bandwidth and resources.</p>

▾ Enabling Dynamic Router Port Learning

Command	ip igmp snooping [vlan <i>vid</i>] mrouter learn pim-dvmrp
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A router port is the port that is connected directly to a multicast device running IGMP snooping and a multicast neighbor device running multicast routing protocol. By default, dynamic router port learning is enabled and the device automatically listens to IGMP Query packets, DVMRP packets, and PIM Hello packets.

▾ Configuring the Aging Time of a Dynamic Router Port

Command	ip igmp snooping dyn-mr-aging-time <i>seconds</i>
Parameter	<i>seconds</i> : Indicates the aging time of a dynamic router port in the unit of seconds. The value ranges from 1 to

Description	3,600.
Command Mode	Global configuration mode
Usage Guide	<p>If a dynamic router port does not receive an IGMP general query packet or a PIM Hello packet before the aging timer expires, the device will delete this port from the router port entry.</p> <p>When dynamic router port learning is enabled, you can run this command to adjust the aging time of the dynamic router port. If the aging time is too short, the multicast device may frequently add or delete a router port.</p>

↘ Configuring the Aging Time of a Dynamic Member Port

Command	ip igmp snooping host-aging-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	<p>The aging time of a dynamic member port indicates the time when a device port receives the IGMP join packet sent from host for subscribing to an IP multicast profile.</p> <p>When the IGMP join packet is received, the aging time of the dynamic member port will be reset. The value of the timer time is host-aging-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. After the aging time is configured, the aging time of following received IGMP join packets will be host-aging-time. This configuration takes effect after the next IGMP join packet is received, and the timer of the port in use will not be refreshed.</p>

↘ Configuring the Maximum Response Time of a Query Packet

Command	ip igmp snooping query-max-response-time <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the maximum response time.
Command Mode	Global configuration mode
Usage Guide	<p>When an IGMP general Query packet is received, the multicast device will reset the aging time of all the dynamic member ports, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port.</p> <p>When an IGMP profile-specific Query packet is received, the multicast device will reset the aging time of all the dynamic member ports of the specific profile, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port.</p>

This configuration takes effect after the next Query packet is received, and the timer in use will not be refreshed. The timer of an IGMPv3 profile-specific Query packet is not refreshed.

↘ Displaying Router Ports

Command	show ip igmp snooping mroute
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>If the router port is successfully configured, an "S" will be displayed in the port information.</p> <pre>Nodexon(config)#show ip igmp snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S)</pre>

↘ Displaying the Information of Dynamic Router Port Learning

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>Run the show ip igmp snooping command to display the aging time and learning status of the dynamic router port.</p> <pre>Dynamic Mroute Aging Time : 300(Seconds) Multicast router learning mode: pim-dvmrp</pre>

↘ Displaying the Information of a Member Port

Command	show ip igmp snooping gda-table
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	<p>If the member port is successfully configured, an "S" will be displayed in the port information.</p> <pre>Nodexon(config)#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/1(S)</pre>
--------------------	--

▾ **Displaying Other Parameters**

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>Run the show ip igmp snooping command to display the aging time of the router port, aging time of the dynamic member port, response time of the query packet, and Report packets suppression, and immediate leave.</p> <pre>IGMP Fast-Leave: Enable IGMP Report suppress: Enable Query Max Response Time: 20(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)</pre>

Configuration Example

▾ **Configuring a Static Router Port and Static Member Port**

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.
	<pre>Nodexon# configure terminal Nodexon(config)# ip igmp snooping vlan 1 mrouter interface GigabitEthernet 0/0 Nodexon(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface GigabitEthernet 0/0 Nodexon(config)# end</pre>

<p>Verification</p>	<p>Run the show ip igmp snooping mrouter and show ip igmp snooping gda-table commands to check whether the configuration takes effect.</p>
	<pre>Nodexon#show ip igmp snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/0(S) Nodexon#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/0(SM)</pre>

➤ **Enabling Report Packet Suppression**

<p>Scenario Figure 8-8</p>	 <p>The diagram illustrates a network topology for IGMP snooping configuration. On the left, a server icon labeled 'Source 1' is connected to 'Device A' (a switch) via a link labeled '10.1.1.1/24' on Device A's 'Gi 0/1' interface. Device A is also connected to 'Device B' (another switch) via a link labeled 'VLAN 1:192.168.1.1' on Device A's 'Gi 0/2' interface and Device B's 'Gi 0/1' interface. Device B is connected to three desktop computer icons labeled 'Receiver 1', 'Receiver 2', and 'Receiver 3' via links labeled 'Gi 0/2', 'Gi 0/3', and 'Gi 0/4' respectively.</p>
	<p>A is the multicast router and is connected directly to multicast Source 1.</p>

	<p>B is a Layer-2 device and is connected directly to the user host and multicast Source 2.</p> <p>Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable Report packets suppression on B.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)#ip igmp snooping ivgl B(config)# ip igmp snooping suppression enable</pre>
Verification	<p>Check whether Receiver 1 and Receiver 2 are added to profile 239.1.1.1, and only the IGMP Report packets of profile 239.1.1.1 are forwarded from interface Gi0/1 of B.</p>
B	<pre>B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Enable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Snooping version: 2IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds)</pre>

	Dynamic Host Aging Time : 260(Seconds)
--	--

↘ Configuring Other Parameters

Configuration Steps	<ul style="list-style-type: none"> ● Configure basic IGMP snooping functions. ● Enable Immediate-leave function. ● Disable router port learning. ● Configure the aging time of a router port. ● Configuring the aging time of a member port. ● Configure the response time of a Query packet.
	<pre>Nodexon# configure terminal Nodexon(config)# ip igmp snooping fast-leave enable Nodexon(config)# no ip igmp snooping mrouter learn pim-dvmrp Nodexon(config)#ip igmp snooping dyn-mr-aging-time 200 Nodexon(config)#ip igmp snooping host-aging-time 100 Nodexon(config)#ip igmp snooping query-max-response-time 60 Nodexon(config)# end</pre>
Verification	Run the show ip igmp snooping command to check whether the configuration is successful.
	<pre>Nodexon#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Enable IGMP Report suppress: Enable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Snooping version: 2Query Max Response Time: 60(Seconds) IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 200(Seconds) Dynamic Host Aging Time : 100(Seconds)</pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

8.4.5 Configuring IGMP Security Control

Configuration Effect

- Configure the range of multicast addresses that a user can access.
- Configure to allow a user from an unauthorized profile to preview a multicast channel.
- Configure the number of multicast addresses that a user can access.
- Configure to limit a user to receive only the multicast traffic from a router port to prevent illegal multicast traffic sent by the end user.
- Configure to limit a user to receive only the multicast traffic from designated source IP addresses to prevent illegal multicast traffic.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

▾ Configuring the Profile Filtering

- Optional.
- If you want to limit the profile packets to be received by a port, you can configure the profile filtering on the port.
- If you want to limit the multicast packets to be received by a VLAN, you can configure the per-VLAN profile filtering.

▾ Enabling Multicast Preview

- Optional.
- You can enable multicast preview for a user from an unauthorized profile.

▾ Configuring the Maximum Number of Profiles

- Optional.
- If you want to limit the number of multicast profiles that a port is allowed to receive, you can configure the maximum number of multicast profiles allowed for this port.
- If you want to limit the number of multicast profiles that global ports are allowed to receive, you can configure the maximum number of multicast profiles allowed for these ports.

▾ Configuring Source Port Inspection

- Optional.
- You can perform this configuration if you want to allow a port to receive only the multicast traffic from the router port.

▾ Configuring Source IP Inspection

- Optional.

- You can perform this configuration to specify the source IP address for all the multicast profiles of all VLANs. Only the multicast traffic whose source IP address is the same as the set one is considered as legal.
- You can also specify the source IP addresses for specific multicast profiles within specific VLANs. Among the multicast traffic received from the specific multicast profiles within the VLANs, only the one with the same source IP address as the set one is considered as legal and will be forwarded by the multicast device; other traffic will be discarded.

Verification

- Run the **show ip igmp snooping interfaces** command to display the profile filtering and the maximum number of multicast profiles for a port.
- Run the **show ip igmp snooping vlan** command to display the per-VLAN profile filtering.
- Run the **show ip igmp snooping** command to check whether the maximum number of global multicast profiles, preview function, source port inspection, and source IP address inspection take effect.

Related Commands

▾ Configuring the Profile Filtering

Command	ip igmp snooping filter <i>profile-number</i>
Parameter Description	<i>profile-number</i> : Indicates a profile number.
Command Mode	Interface configuration mode
Usage Guide	N/A

▾ Configuring the Per-VLAN Profile Filtering

Command	ip igmp snooping vlan <i>vid filter profile-number</i>
Parameter Description	<i>vid</i> : Indicates a VLAN. The value ranges from 1 to 4,094. <i>profile-number</i> : Indicates a profile number.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Maximum Number of Profiles on a Port

Command	ip igmp snooping max-groups <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Interface configuration mode
Usage Guide	This value indicates only the number of dynamic multicast profiles, and the number of static profiles is not

included. The counter of multicast profiles is based on the VLAN that the port belongs to. For example, if a port belongs to three VLANs, and all three of them receive a request packet from multicast profile 224.1.1.1 simultaneously, then the counter of multicast profiles will be 3 but not 1.

↘ Configuring the Maximum Number of Global Profiles

Command	ip igmp snooping l2-entry-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of multicast profiles.
Command Mode	Global configuration mode
Usage Guide	This value includes the number of both dynamic profiles as well as static profiles.

↘ Configuring Source Port Inspection

Command	ip igmp snooping source-check port
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After source port inspection is enabled, the multicast traffic received by a device will be discarded if no router port is detected in the network environment.

↘ Configuring Source IP Inspection

Command	ip igmp snooping source-check default-server <i>source-address</i>
Parameter Description	<i>source-address</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling Source IP Inspection for a Specific Profile

Command	ip igmp snooping limit-ipmc vlan <i>vid</i> address <i>group-address</i> server <i>source-address</i>
Parameter Description	<i>vid</i> vlan id <i>group-address</i> : Indicates a profile address. <i>source-address</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Enabling Preview

Command	ip igmp snooping preview <i>profile-number</i>
Parameter Description	<i>profile number</i> : Indicates the range of multicast addresses allowed for preview. The value ranges from 1 to 1,024.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Preview Duration

Command	ip igmp snooping preview interval <i>num</i>
Parameter Description	<i>num</i> : Specifies the preview duration which ranges from 1s to 300s (60s by default).
Command Mode	Global configuration mode
Usage Guide	This configuration allows unauthorized users to receive multicast traffic within the preview duration. After the duration is met, the preview will be stopped; the preview can be resumed in 300s.

▾ Displaying the Per-Port Profile Filtering

Command	show ip igmp snooping interface						
Parameter Description	N/A						
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode						
Usage Guide	<p>If the function is configured, the profile will be displayed, for example:</p> <pre>Nodexon#show ip igmp snooping interfaces gigabitEthernet 0/1</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Filter profile number</th> <th>max-group</th> </tr> </thead> <tbody> <tr> <td>GigabitEthernet 0/1</td> <td>1</td> <td></td> </tr> </tbody> </table>	Interface	Filter profile number	max-group	GigabitEthernet 0/1	1	
Interface	Filter profile number	max-group					
GigabitEthernet 0/1	1						

▾ Displaying the Per-VLAN Profile Filtering

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the function is configured, the profile will be displayed, for example:

	IGMP VLAN filter: 1
--	---------------------

▾ **Displaying the Maximum Number of Interface Profiles**

Command	show ip igmp snooping interface						
Parameter Description	N/A						
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode						
Usage Guide	<p>If the maximum number of multicast addresses for a port is configured, the value will be displayed, for example:</p> <pre>Nodexon#show ip igmp snooping interfaces gigabitEthernet 0/1</pre> <table border="1" style="margin-left: 40px;"> <thead> <tr> <th style="text-align: left;">Interface</th> <th style="text-align: left;">Filter profile number</th> <th style="text-align: left;">max-group</th> </tr> </thead> <tbody> <tr> <td style="border-top: 1px dashed black;">GigabitEthernet 0/1</td> <td style="border-top: 1px dashed black;">1</td> <td style="border-top: 1px dashed black;">200</td> </tr> </tbody> </table>	Interface	Filter profile number	max-group	GigabitEthernet 0/1	1	200
Interface	Filter profile number	max-group					
GigabitEthernet 0/1	1	200					

▾ **Displaying the Maximum Number of Global Profiles**

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>If the function is configured, the profile will be displayed, for example:</p> <pre>IGMP Snooping L2-entry-limit: 65536</pre>

▾ **Displaying the Information of Source Port Inspection**

Command	show ip igmp snooping vlan
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	<p>If source port inspection is enabled, the following information will be displayed:</p> <pre>Source port check: Enable</pre>

▾ **Displaying the Information of Source IP Inspection**

Command	show ip igmp snooping vlan
----------------	-----------------------------------

Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If source IP address inspection is enabled, the following information will be displayed: <pre>Source ip check: Enable</pre>

▾ **Displaying the Information of the Preview Function**

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If the range of multicast addresses for a port is configured, preview will be enabled, for example: <pre>IGMP Preview: Enable</pre> <pre>IGMP Preview group aging time : 60(Seconds)</pre>

Configuration Example

▾ **Configuring the Profile Filtering and the Maximum Number of Demanded Profiles**

<p>Scenario Figure 8-9</p>	
<p>A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1. By configuring VLAN 1, you can configure to allow the users within VLAN 1 to receive only the profiles</p>	

	<p>whose addresses range from 225.1.1.1 to 225.1.255.255.</p> <p>You can configure Receiver 1 to receive only the profiles whose addresses range from 225.1.1.1 to 225.1.1.255, Receiver 2 to receive only the profiles whose addresses range from 225.1.2.1 to 255.1.2.255, and Receiver 3 to receive only the profiles whose addresses range from 225.1.3.1 to 225.1.3.255.</p> <p>At most 10 profiles can be added to a port and at most 100 profiles can be added globally.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Configure the range and maximum number of multicast addresses on B.
A	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>

➤ **Configuring Source Port Inspection**

<p>Scenario</p> <p>Figure 8-10</p>	
	<p>A is the multicast router and is connected directly to multicast Source 1.</p> <p>B is a Layer-2 device and is connected directly to the user host and multicast Source 2.</p> <p>Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.</p> <p>Source 1 sends the multicast address traffic from profile 224.1.1.1, and Source 2 sends the multicast address traffic from profile 225.1.1.1.</p> <p>Receiver 1 can request profiles 224.1.1.1 and 225.1.1.1 respectively.</p> <p>Source port inspection is enabled.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.
<p>A</p>	<pre>A# configure terminal</pre>

	<pre>A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>
B	<pre>B# configure terminal B(config)#ip igmp snooping ivgl B(config)#ip igmp snooping source-check port</pre>
Verification	<ul style="list-style-type: none"> ● Run the show ip igmp snooping mroute command to check whether Gi0/1 is learned as a router port. ● Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and cannot request that of profile 225.1.1.1.
B	<pre>Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S) B#show ip igmp snooping IGMP Snooping L2-entry-limit: 100 Source port check: Enable Source ip check: Disable</pre>

↘ Configuring Source IP Inspection

<p>Scenario</p> <p>Figure 8-11</p>	
	<p>A is the multicast router and is connected directly to multicast Source 1.</p> <p>B is a Layer-2 device and is connected directly to the user host and multicast Source 2.</p> <p>Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.</p> <p>Source 1 sends the multicast address traffic from profiles 10.1.1.1 and 224.1.1.1, Source 2 sends the multicast address traffic from profiles 192.168.1.3 and 225.1.1.1, and Source 3 sends the multicast address traffic from profiles 192.168.1.3 and 226.1.1.1.</p> <p>Receiver 1 can request profiles 224.1.1.1, 225.1.1.1, and 226.1.1.1 respectively.</p> <p>The default IP address for source IP inspection is 10.1.1.1.</p> <p>Configure limit-ipmc and the multicast traffic of profile 225.1.1.1, and set the legal source address as 192.168.1.3.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode. ● Enable source port inspection on B.
<p>A</p>	<pre>A# configure terminal A(config)# ip multicast-routing A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit</pre>

B	<pre>B# configure terminal B(config)#ip igmp snooping ivgl B(config)# ip igmp snooping source-check default-server 10.1.1.1 B(config)# ip igmp snooping limit-ipmc vlan 1 address 225.1.1.1 server 192.168.1.3</pre>
Verification	<ul style="list-style-type: none"> ● Run the show ip igmp snooping command to check whether source IP inspection is enabled. ● Check whether Receiver 1 can request the multicast traffic of profile 224.1.1 and 225.1.1.1 and cannot request that of profile 226.1.1.1.
B	<pre>B#show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Enable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)</pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.
- The multicast router port is not learned, leading to failure to receive the multicast traffic.
- The IP address for source IP inspection is inconsistent with the multicast IP address, leading to failure to receive the multicast traffic.

8.4.6 Configuring an IGMP Profile

Configuration Effect

- Create an IGMP filtering profile.

Configuration Steps

↳ Creating a Profile

- (Optional) Create an IGMP filtering profile.
- ↳ **Configuring the Profile Range**
- (Optional) Configure the range of multicast profile addresses.
- ↳ **Configuring the Profile Filtering**
- (Optional) Configure the filtering mode of profile to **permit** or **deny**.

Verification

- Run the **show running-config** command to check whether the preceding configurations take effect.

Related Commands

↳ Creating a Profile

Command	ip igmp profile <i>profile-number</i>
Parameter Description	<i>profile-number</i> : Indicates the number of a profile.
Command Mode	Global configuration mode
Usage Guide	

↳ Configuring the Profile Range

Command	range <i>low-ip-address</i> [<i>high-ip-address</i>]
Parameter Description	<i>low-ip-address</i> : Specifies the start address. <i>high-ip-address</i> : Specifies the end address. Only one address is configured by default.
Command Mode	Profile configuration mode
Usage Guide	You can configure multiple addresses. If the IP addresses of different ranges are consecutive, the addresses will be combined.

↳ Configuring the Profile Filtering

Command	deny
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to deny while the range of multicast profiles is not specified, no profile is to be denied, which means to permit all profiles.

↘ Configuring the Profile Filtering

Command	permit
Parameter Description	N/A
Command Mode	Profile configuration mode
Usage Guide	If the filtering mode of profile is set to permit while the range of multicast profiles is not specified, no profile is to be permitted, which means to deny all profiles.

Configuration Example

↘ Creating a Filtering Profile

Configuration Steps	<ul style="list-style-type: none"> ● Create a filtering profile.
	<pre>B(config)#ip igmp profile 1 B(config-profile)#permit B(config-profile)#range B(config-profile)#range 224.1.1.1 235.1.1.1 B(config-profile)#</pre>
Verification	Run the show running-config command to check whether the configuration is successful.
	<pre>ip igmp profile 1 permit range 224.1.1.1 235.1.1.1 !</pre>

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.
- The mode of profile is set to **permit** while the range of multicast profiles is not specified, leading to the denial of all profiles.

8.4.7 Configuring IGMP QinQ

Configuration Effect

- Create a multicast entry on the VLAN where IGMP packets are located. Forward IGMP packets on the VLAN where these packets are located, realizing transparent transmission.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

Configuring QinQ Transparent Transmission

- If the QinQ interface needs to forward multicast packets on the VLANs where the VIDs of the packets specify, enable QinQ to realize transparent transmission.

Verification

- Run the **show ip igmp snooping** command to check whether the configuration takes effect.

Related Commands

Configuring QinQ Transparent Transmission

Command	ip igmp snooping tunnel
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable QinQ to realize transparent transmission of IGMP packets.

Displaying QinQ Configuration

Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. <pre>IGMP Tunnel: Enable</pre>

Configuration Example

Configuring QinQ Transparent Transmission

Configuration Steps	<ul style="list-style-type: none"> Configure basic IGMP snooping functions. Configure QinQ transparent transmission.
	<pre>Nodexon# configure terminal Nodexon(config)# ip igmp snooping tunnel</pre>

	Nodexon(config)# Nodexon(config)# end
Verification	Run the show ip igmp snooping command to check whether the configuration is successful.
	IGMP Tunnel: Enable

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

8.4.8 Configuring an IGMP Querier

Configuration Effect

- Configure the device as an IGMP querier, which will send IGMP Query packets periodically and collect user demanding information.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

▾ Enabling the Querier Function

- (Optional) Enable IGMP querier function globally or for a specified VLAN.
- (Optional) Disable the IGMP querier function for a specified VLAN.

▾ Configuring the Source IP Address of a Querier

- (Optional) You can configure the source IP address of a Query packet sent by the querier based on VLANs.
- After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect.

▾ Configuring the Maximum Response Time of a Query Packet

- (Optional) Adjust the maximum response time carried by an IGMP Query packet. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1.

▾ Configuring the Query Interval of a Querier

- (Optional) Adjust the interval of the IGMP querier for sending query packets.

▾ Configuring the Aging Timer of a Querier

- (Optional) Configure the aging timer of other IGMP queriers on the network.

▾ Specifying the IGMP Version for a Querier

- (Optional) Specify the IGMP version for a querier (IGMPv2 by default).

Verification

- Run the **show ip igmp snooping querier detail** command to check whether the configuration takes effect.

Related Commands

↳ Enabling the IGMP Querier Function

Command	ip igmp snooping [vlan <i>vid</i>] querier
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	IGMP querier for a specified VLAN will take effect only after global IGMP querier is enabled. If global IGMP querier is disabled, IGMP querier for all the VLANs will be disabled.

↳ Configuring the Source IP Address of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier address <i>a.b.c.d</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>a.b.c.d</i> : Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect. If the source IP address is specified by a VLAN, the address will be used preferentially.

↳ Configuring the Maximum Response Time of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier max-response-time <i>seconds</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>seconds</i> : Indicates the maximum response time. in the unit of seconds. The value ranges from 1 to 25.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

↳ Configuring the Query Interval of a Querier

Command	ip igmp snooping [vlan <i>vid</i>] querier address <i>a.b.c.d</i>
Parameter Description	vlan <i>vid</i> : Specifies a VLAN. This configuration applies to all VLANs by default. <i>seconds</i> : Indicates the query interval in the unit of seconds. The value ranges from 1 to 18,000.
Command	Global configuration mode

Mode	
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

↘ Configuring the Aging Timer of a Querier

Command	ip igmp snooping [vlan vid] querier timer expiry seconds
Parameter Description	vlan vid: Specifies a VLAN. This configuration applies to all VLANs by default. seconds: Indicates the timeout time in the unit of seconds. The value ranges from 60 to 300.
Command Mode	Global configuration mode
Usage Guide	A device may fail to be elected as the querier even when its querier function is enabled. If a device that fails to be elected does not receive the Query packet sent by the querier in the aging time, the querier in use is considered as expired, and a new round of election will be raised. If the aging time is specified by a VLAN, the value will be used preferentially.

↘ Specifying the IGMP Version for a Querier

Command	ip igmp snooping [vlan vid] querier version 1
Parameter Description	vlan vid: Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A querier can be run in IGMPv1 and IGMPv2 (IGMPv2 by default). You can also run a command to configure the version to IGMPv1. If the IGMP version for a querier is specified by a VLAN, the version will be used preferentially.

↘ Displaying the IGMP Querier Configuration

Command	show ip igmp snooping querier detail
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed. <pre>Nodexon(config)#show ip igmp snooping querier detail Vlan IP Address IGMP Version Port ----- Global IGMP switch querier status</pre>

	<pre> ----- admin state : Enable admin version : 2 source IP address : 1.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 Vlan 1: IGMP switch querier status ----- admin state : Disable admin version : 2 source IP address : 1.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 operational state : Disable operational version : 2 </pre>
--	---

Configuration Example

▾ Enabling the IGMP Querier Function

<p>Scenario</p> <p>Figure 8-12</p>	<p>The diagram illustrates a network topology where a source (Source1) is connected to a central device (Device A) through a VLAN1 interface on port Gi 0/1. The source IP address is 10.1.1.1/24. Device A is also connected to a receiver (Receiver 1) through a VLAN1 interface on port Gi 0/2. This setup represents a Layer-2 network configuration for IGMP snooping.</p>
	<p>In the scenario without Layer-3 multicast equipment, the multicast traffic can be forwarded only on the Layer-2 network.</p> <p>A acts as a Layer-2 device to connect to the multicast source and receiver.</p>

Configuration Steps	<ul style="list-style-type: none"> ● Enable global IGMP snooping on A in IVGL mode. ● Enable IGMP querier for VLAN 1 on A.
A	<pre>A(config)#ip igmp snooping ivgl A(config)#ip igmp snooping querier A(config)#ip igmp snooping querier address 10.1.1.1 A(config)#ip igmp snooping vlan 1 querier</pre>
Verification	Run the show ip igmp snooping querier command to check whether the querier of VLAN 1 takes effect.
A	<pre>A(config)#show ip igmp snooping querier Vlan IP Address IGMP Version Port ----- 1 10.1.1.1 2 switch A(config)#show ip igmp snooping querier vlan 1 Vlan 1: IGMP switch querier status ----- elected querier is 10.1.1.1 (this switch querier) ----- admin state : Enable admin version : 2 source IP address : 10.1.1.1 query-interval (sec) : 60 max-response-time (sec) : 10 querier-timeout (sec) : 125 operational state : Querier operational version : 2</pre>

Common Errors

- The source IP address is not configured for the querier and the querier does not take effect.

8.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the statistics on IGMP snooping.	clear ip igmp snooping statistics
Clears the dynamic router ports and member ports.	clear ip igmp snooping gda-table

Displaying

Description	Command
Displays basic IGMP snooping configurations.	show ip igmp snooping [vlan <i>vlan-id</i>]
Displays the statistics on IGMP snooping.	show ip igmp snooping statistics [vlan <i>vlan-id</i>]
Displays the router ports.	show ip igmp snooping mrouter
Displays the IGMP snooping entries.	show ip igmp snooping gda-table
Displays the profile.	show ip igmp profile [<i>profile-number</i>]
Displays the IGMP snooping configurations on an interface.	show ip igmp snooping interface <i>interface-name</i>
Displays the IGMP querier.	show ip igmp snooping querier [detail]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all IGMP Snooping functions.	debug igmp-snp
Debugs the IGMP snooping events.	debug igmp-snp event
Debugs the IGMP snooping packets.	debug igmp-snp packet
Debugs the communications between IGMP snooping and MSF.	debug igmp-snp msf
Debugs the IGMP snooping alarms.	debug igmp-snp warning

9 Configuring MLD Snooping

9.1 Overview

Multicast Listener Discovery (MLD) Snooping is used to control and manage the forwarding behaviors of IPv6 multicast packets at Layer 2.

The device running MLD Snooping analyzes MLD packets received by a port to create a mapping between the port and the MAC multicast address and forwards IPv6 multicast data at Layer 2 based on the mapping. When MLD Snooping is disabled, IPv6 multicast data packets are broadcasted at Layer 2. When MLD Snooping is enabled, multicast data packets of a known IPv6 multicast group are forwarded to a specified receiver at Layer 2 instead of being broadcasted at Layer 2.

Protocols and Standards

RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches

9.1.1 Two Types of MLD Snooping Ports

As shown in Figure 9-1, the Layer-3 multicast device is connected to the multicast source. MLD Snooping is enabled on the access device. Host A and Host B are receivers (that is, members of the IPv6 multicast group).

Figure 9-1 Two Types of MLD Snooping Ports

- Multicast router port: Indicates the port on the access device for connecting to the Layer-3 multicast device, for example, Port Eth0/1 of the access device.
- Member port: Is short for IPv6 multicast group member port, also called listener port, and indicates the port on the access device for connecting to an IPv6 multicast group member, for example, Port Eth0/2 and Port Eth0/3 on the access device.

9.1.2 Work Mode of MLD Snooping

- **DISABLE mode:** MLD Snooping does not take effect in this mode. That is, the Layer-2 multicast device does not "snoop" MLD packets between the host and the router, and multicast streams are broadcasted within VLANs.
- **Independent VLAN Group Learn (IVGL) mode:** In this mode, multicast streams between VLANs are mutually independent. A host can request only the multicast router port in the same VLAN as the host to receive multicast packets, and can forward the received multicast data packets of any VLAN only to the member port and multicast router port in the same VLAN as the host.
- **Shared VLAN Group Learn (SVGL) mode:** In this mode, hosts of VLANs share the same multicast stream. A host in one VLAN can request multicast streams of another VLAN. When a shared VLAN is specified, only the multicast data streams of this VLAN can be forwarded to hosts of other VLANs. Multicast data streams of a shared VLAN, can be forwarded to the member ports of this multicast address, even though some member ports do not belong to the shared VLAN. In SVGL mode, MLD profiles must be used to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. By default, all the group ranges are not within the SVGL application ranges, and all the multicast packets are discarded.
- **IVGL-SVGL mode:** In this mode, IVGL and SVGL coexist. You can use MLD profiles to allocate a batch of multicast address ranges to SVGL. Within the multicast address ranges, member ports in the multicast forwarding entries support trans-VLAN packet forwarding. Member ports in the multicast forward entries corresponding to other multicast address ranges must belong to the same VLAN.

9.1.3 Working Principle of MLD Snooping

The device running MLD Snooping processes different MLD packets as follows:

MLD QUERY

The Layer-3 multicast device regularly sends an MLD General Query packet to all hosts and routers (with the address of FF02::1) in the local network segment, to query the IPv6 multicast group members in this network segment. When receiving the MLD General Query packet, the device running MLD Snooping forwards the packet all ports in the VLAN except the one receiving the packet, and processes the port receiving the packet as follows:

- If the port is already in the router multicast port list, its aging timer is reset.
- If the port is not contained in the router multicast port list, the port is added to the router multicast port list and its aging timer is started.
- Each time the Layer-2 multicast device receives an MLD General Query packet, it starts the aging timer for each member port, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.
- Each time the Layer 2 multicast device receives a MLD Group-Specific Query packet, it starts the aging timer for each member port in the specific group, and updates the timer time to the configured maximum response time of MLD query packet. When the aging timer time of a port is reduced to 0, it is deemed that no member receives multicast streams through this port, and therefore, the Layer-2 multicast device deletes the port from the MLD Snooping forwarding table.

- When the Layer-2 multicast device receives a MLD Group-Specific Query packet, it no longer updates the preceding two types of timers.

MLD REPORT

In either of the following cases, the host sends an MLD Membership Report packet to the MLD querier.

- After receiving an MLD query (General Query or Group-Specific Query) packet, an IPv6 multicast group member host responds with an MLD Membership Report packet.
- If a host needs to join an IPv6 multicast group, it actively sends an MLD Membership Report packet to MLD querier to request to join this IPv6 multicast group.

When receiving an MLD Membership Report packet, the device running MLD Snooping forwards it to all multicast router ports in the VLAN, retrieves, from the packet, the address of the IPv6 multicast group that the host needs to join, and processes the port receiving the packet as follows:

- If there is no forwarding entry corresponding to the IPv6 multicast group, the forwarding entry is created, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group but the port is not contained in the egress port list, the port is added to the egress port list as a dynamic member port, and its aging timer is started.
- If there is a forwarding entry corresponding to the IPv6 multicast group and dynamic member port is contained in the egress port list, its aging timer is reset.

MLD LEAVE

When a host leaves an IPv6 multicast group, it sends an MLD Leave packet (with the address of FF02::2) to notify the multicast router that it has left the IPv6 multicast group. When receiving an MLD Leave packet from a member port, the device running MLD Snooping directly forwards it to the multicast router port. If the fast leave function is enabled, the device directly deletes the port from the forwarding port list of the relevant multicast group.

9.1.4 Source Port Check

The source port check function of MLD Snooping improves the network security.

This function strictly limits the ingress ports of MLD multicast streams. When this function is disabled, multicast streams from any port are valid and the Layer-2 multicast device forwards them to registered member ports according to the forwarding list of MLD Snooping. When this function is enabled, multicast streams only from the multicast router ports are valid and the Layer-2 multicast device forwards them to registered ports. Multicast data streams from non-multicast router ports are invalid and discarded.

9.2 Applications

Application	Description
MLD Snooping SVGL Trans-VLAN	MLD Snooping works in SVGL mode

Application	Description
Multicast On demand	
Source Port Filtering	Multicast streams only from multicast router ports are received.

9.2.1 MLD Snooping SVGL Trans-VLAN Multicast On demand

Scenario

As shown in Figure 9-2, Host A of VLAN 3 and Host B of VLAN 4 order a video. The video streams are in VLAN 2.

- Enable the SVGL mode on the access device and set a shared VLAN 2.

Figure 9-2

Remarks	VLAN 2 is a shared VLAN. VLAN 3 and VLAN 4 are the VLANs through which the video on-demand service is output.
----------------	--

Deployment

- Enable the Layer-3 multicast protocol on the Layer-3 multicast device.
- Enable the SVGL mode on the Layer-2 device.

9.2.2 Source Port Filtering

Scenario

As shown in Figure 9-3, when the source port check function is configured, video streams can be received only from the source multicast router port. Multicast video streams from other ports are invalid and discarded. Note that when the source port check function is configured, there shall be at least one multicast router port. Otherwise, packet filtering is not performed on the multicast router port even though the source port filtering is enabled. When the source port check function is not configured, multicast video streams from all ports are received by default.

- Enable the IVGL mode on the access device.

Figure 9-3

Remarks	<p>Port Eth0/1 is a multicast router port and Port Eth0/2 is a non-multicast router port.</p> <p>Video servers send same multicast video streams.</p> <p>Hosts A and B can receive multicast streams only from Video Server A.</p>
----------------	--

Deployment

- Enable the source port check function and configure a static multicast router port.
- Enable the IVGL mode on the Layer-2 device.

9.3 Features

Basic Concepts

▾ Multicast Router Port and Member Port

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. If MLD Snooping is enabled, when the dynamic multicast router port learning function is enabled on a port, after receiving an MLD Query or PIMv6-Hello packet, the port learns the dynamic multicast router port and starts the aging timer of the dynamic multicast router port. A static multicast router port can be added by configuring the **ipv6 mld snooping vlan mrouter** command.

Member ports are classified into dynamic member ports and static member ports. If MLD Snooping is enabled, after receiving an MLD Report packet, a port learns the dynamic member router port and starts the aging timer of the dynamic member port. A static member port can be added by configuring the **ipv6 mld snooping vlan static interface** command.

▾ Fast Leave and Packet Suppression

When the fast leave function is enabled, a port is directly deleted after receiving an MLD Leave packet. The fast leave function is applicable only to scenarios in which only one user is connected to a port, and helps save the bandwidth. When multiple users are connected to a port, if the fast leave function is enabled, other users wanting to receive packets fail to receive any packets.

When the packet suppression function is enabled, only the first MLD Report packet is forwarded within one query period.

Overview

Feature	Description
Globally Enabling MLD Snooping	Globally enables MLD Snooping and configures the work mode.
VLAN-based MLD Snooping	Enables or disables MLD Snooping for a single VLAN when MLD Snooping is globally enabled.
Aging Time of Multicast Router Ports	Adjusts the aging time of dynamic multicast router ports. The default aging time is 300s.
Dynamic Multicast Router Port Learning	After receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.
Fast Leave of Multicast Group Member Ports	A member port can be quickly deleted, instead of being aged and deleted after the query interval of a Group-Specific Query expires.
MLD Report Packet Suppression	Only the first Report packet is processed within one query period, reducing the work load of the module.
Source Port Check	Multicast streams received only from a multicast router port can be forwarded. Packets received from non-multicast router ports cannot be forwarded.
Port-based Specific Multicast Group Filtering	Only multicast group packets that meet the filter conditions can be received.
Maximum Number of Multicast Groups Supported by a Port	Limits the maximum number of multicast groups that a port can join.

9.3.1 Globally Enabling MLD Snooping

Globally enable MLD Snooping and configure the work mode. Multicast forwarding entries can be learnt and multicast streams are forwarded to a specified port.

Working Principle

Enable MLD Snooping. When an MLD Report packet with the time to live (TTL) of 1 is received, a multicast forwarding entry is created and the forwarding egress is this port.

↳ Learning a Dynamic Member Port

After a valid MLD Report packet is received, a dynamic member port is learnt and a forwarding entry is generated. The forwarding egress of this entry is the member port.

↳ Coordinating Parameters

Configure the MLD Report packet suppression function.

Related Configuration

Configure the MLD Report packet suppression function so that only the first Report is processed within one query period, thereby reducing the number of packets in the network.

9.3.2 VLAN-based MLD Snooping

Enable or disable MLD Snooping for a single VLAN. By default, if MLD Snooping is globally enabled, the MLD Snooping function of each VLAN is enabled.

Related Configuration

Globally configure MLD Snooping. Then configure MLD Snooping for a single VLAN.

9.3.3 Aging Time of Multicast Router Ports

Multicast router ports are classified into dynamic multicast router ports and static multicast router ports. By default, the aging time of a dynamic multicast router port is 300s. Static multicast router ports are not aged.

Related Configuration

Ability of learning from dynamic multicast router port learning function

9.3.4 Dynamic Multicast Router Port Learning

By default, all ports support the dynamic multicast router port learning function.

Working Principle

When a port supports the dynamic multicast router port learning function, after receiving an MLD query packet or a PIMv6 Hello packet, the port is learnt as a dynamic multicast router port.

Related Configuration

Configure a port as a static multicast router port.

9.3.5 Aging Time of Dynamic Member Ports

Member ports are classified into dynamic member ports and static member ports. By default, the aging time of a dynamic member port is 260s. Static member ports are not aged.

9.3.6 Fast Leave of Multicast Group Member Ports

By default, the fast leave function of multicast group member ports are disabled. If the fast leave function is enabled, the port is directly deleted after receiving a done packet.

9.3.7 MLD Report Packet Suppression

By default, the MLD report packet suppression function is disabled. If the function is enabled, only the first Report packet is processed within one query interval, thereby reducing the number of packets in the network.

9.3.8 Source Port Check

The source port check function is disabled by default.

Working Principle

When the source port check function is enabled, packets only from multicast router ports are valid and packets from non-multicast router ports are invalid.

Related Configuration

Configure a port as a static multicast router port.

9.3.9 Port-based Specific Multicast Group Filtering

Under certain circumstances, you may use the port filtering function to control a port to forward multicast packets only of a certain range.

9.3.10 Maximum Number of Multicast Groups Supported by a Port

The maximum number of multicast groups that a port is allowed to join can control the maximum number of multicast groups supported by the port.

9.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of MLD Snooping	ipv6 mld snooping	Enables MLD Snooping and specifies the work mode.
	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>	Configures the static multicast router port.
	ipv6 mld snooping vlan <i>vlan-id</i> static <i>ip-addr</i> interface <i>interface-id</i>	Configures a static member port.
	ipv6 mld profile <i>profile-num</i>	Configures a profile.
	ipv6 mld snooping source-check port	Configures source port check.

	ipv6 mld snooping filter <i>profile-num</i>	Configures multicast group filtering for a port.
	ipv6 mld snooping max-groups <i>num</i>	Configures the maximum number of multicast groups that a port can join.

9.4.1 Configuring Basic Functions of MLD Snooping

Configuration Effect

- Enable MLD Snooping and configure the work mode.

Notes

- Enable MLD Snooping and set the work mode to SVGL. The MLD Snooping SVGL mode cannot coexist with IPv4 or IPv6 Layer-3 multicasting.
- When the work mode is SVGL or IVGL-SVGL, a profile must be associated to specify the multicast group range in which the SVGL mode applies.

Configuration Steps

↳ Enabling IPv6 MLD Snooping

- Mandatory.

Verification

Run the **show ipv6 mld snooping** command to check whether MLD Snooping is enabled.

- Check whether the device can create correct multicast forwarding entries.

Related Commands

↳ Enabling IPv6 MLD Snooping

Command	ipv6 mld snooping <i>mode</i>
Parameter Description	mode : Specifies the work mode.
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Configuring a Profile

Command	ipv6 mld profile <i>profile-num</i>
Parameter Description	profile-num : Indicates the profile number.

Command Mode	Global configuration mode
Usage Guide	Run this command to configure a profile and enter the profile configuration mode.

↘ Configuring a Static Multicast Router Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> mrouter interface <i>interface-id</i>
Parameter Description	vlan-id: Indicates the VLAN ID. interface-id: Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring a Static Member Port

Command	ipv6 mld snooping vlan <i>vlan-id</i> static <i>ip-addr</i> interface <i>interface-id</i>
Parameter Description	vlan-id: Indicates the VLAN ID. ip-addr: Indicates the group address. interface-id: Indicates interface changes.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring Source Port Check

Command	ipv6 mld snooping source-check port
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring Port-based Multicast Group Filtering

Command	ipv6 mld snooping filter <i>profile-num</i>
Parameter Description	profile-num: Indicates the profile number.
Command Mode	Interface configuration port
Usage Guide	N/A

↘ Configuring the Maximum Number of Multicast Groups Supported by a Port

Command	ipv6 mld snooping max-groups <i>num</i>
Parameter Description	<i>num</i> : Indicates the number of groups.
Command Mode	Interface configuration port
Usage Guide	N/A

▾ Configuring Report Packet Suppression

Command	ipv6 mld snooping suppression enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the Report packet suppression function is enabled, only the first Report packet of a specific VLAN and group is forwarded to a multicast router port within one query interval. The subsequent Report packets are forwarded to the multicast router port, so as to reduce the number of packets in the network. This function can only suppress the Report packets of MLDv1. It is invalid on the Report packets of MLDv2.

▾ Configuring Port Fast Leave

Command	ipv6 mld snooping fast-leave enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When the port fast leave function is enabled, after receiving a Leave packet, the port is directly deleted from the member ports in the corresponding forwarding entries. Later, when receiving a relevant Group-Specific Query packet, the device does not forward the packet to this port. The Leaver packet includes the Leave packet of MLDv1, include type of MLDv2, and Report packet containing no source address. This function is applicable only to scenarios in which only one user is connected to a port, and helps save bandwidth and resources.

▾ Configuring Dynamic Multicast Router Port Learning

Command	ipv6 mld snooping [<i>vlan vid</i>] mrouter learn
Parameter Description	<i>vlan-id</i> : Specifies a VLAN ID. This function is applicable to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A multicast router port is a port that directly connects an MLD Snooping-enabled multicast device to a

	neighbor multicast device in which a multicast routing protocol is enabled. By default, when the dynamic multicast router port learning function is enabled, the device automatically listens to the MLD Query/PIM Hello packet and dynamically identifies a multicast router port.
--	---

📌 Configuring Aging Time of Dynamic Multicast Router Ports

Command	ipv6 mld snooping dyn-mr-aging-time <i>seconds</i>
Parameter Description	seconds: Indicates the aging time of dynamic multicast router ports. The unit is second and the value ranges from 1 to 3,600.
Command Mode	Global configuration mode
Usage Guide	If a dynamic multicast router port does not receive an MLD General Query packet or a PIM Hello packet before the timeout of its aging time, the device deletes the port from the multicast router port list. When the dynamic multicast router learning function is enabled, you can use this command to adjust the aging time of dynamic multicast router ports. If the aging time is too short, a multicast router port may be added and deleted frequently.

📌 Configuring Aging Time of Dynamic Member Ports

Command	ipv6 mld snooping host-aging-time <i>seconds</i>
Parameter Description	seconds: Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	The aging time of a dynamic member port refers to the aging time set when a dynamic member port of a device receives from the host an MLD packet of joining a certain IPv6 multicast group. After receiving an MLD Join packet from a dynamic member port, the device resets the aging timer of the dynamic member port and sets the timer time to host-aging-time. If the timer times out, it is deemed that no user host receives multicast packets through this port, and then the multicast device deletes the port from the MLD Snooping member port list. After this command is configured, the aging timer value of dynamic member ports when MLD Join packets are received subsequently is host-aging-time. The aging time takes effect immediately after configuration and the timers of started member ports are updated.

📌 Configuring Response Time of Query Packets

Command	ipv6 mld snooping query-max-response-time <i>seconds</i>
Parameter Description	seconds: Indicates the response time.
Command Mode	Global configuration mode
Usage Guide	After receiving an MLD General Query packet from a port, the multicast device resets the aging timers of all

	<p>dynamic member ports and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list.</p> <p>After receiving an MLD Group-Specific Query packet from a port, the multicast device resets the aging timers of all dynamic member ports in the specific group and sets the timer time to query-max-response-time. If the timer times out, it is deemed that no user host receives multicast packets through the port, and then the multicast device deletes the port from the MLD Snooping member port list.</p> <p>The configuration takes effect when the a query packet is received next time, and the configuration of currently started timers are not updated. For Group-Specific Query packets of MLDv2, timers are not updated.</p>
--	--

▾ Checking Multicast Router Ports

Command	show ipv6 mld snooping mroute
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>If a multicast router port is successfully configured, the mark "S" is shown in the interface information displayed. For example:</p> <pre>Nodexon(config)#show ipv6 mld snooping mrouter Multicast Switching Mroute Port D: DYNAMIC S: STATIC (*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/1(S)</pre>

▾ Checking Dynamic Multicast Router Port Learning

Command	show ipv6 mld snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>Run the show ip igmp snooping command to check the aging time and learning status of dynamic multicast router ports.</p> <pre>Dynamic Mroute Aging Time : 300(Seconds)</pre>

```
Multicast router learning mode: Enable
```

↘ Checking Member Ports

Command	show ipv6 mld snooping gda-table
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>If a member port is successfully configured, the mark "S" is shown in the interface information displayed. For example:</p> <pre>Nodexon(config)#show ipv6 mld snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, FF15::100, 1): VLAN(1) 2 OPORTS: GigabitEthernet 3/7(S)</pre>

↘ Checking Other Parameters

Command	show ipv6 mld snooping
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, interface configuration mode
Usage Guide	<p>Run the show ipv6 mld snooping command to check the aging time of multicast router ports, aging time of dynamic member ports, response time of query packet, and Report packet suppression, and fast leave parameters.</p> <pre>MLD-snooping mode: IVGL Source port check: Disable MLD Fast-Leave: Disable MLD Report suppress: Disable Query Max Response Time: 10 (Seconds) Dynamic Mroute Aging Time: 300(Seconds)</pre>

Dynamic Host Aging Time: 260(Seconds)

9.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears MLD Snooping multicast forwarding entries.	clear ipv6 mld snooping gda-table
Clears MLD Snooping statistics.	clear ipv6 mld snooping statistics

Displaying

Description	Command
Displays the current MLD Snooping mode.	show ipv6 mld snooping
Displays MLD Snooping forwarding entries.	show ipv6 mld snooping gda-table
Displays MLD Snooping statistics.	show ipv6 mld snooping statistics
Displays MLD Snooping multicast router ports.	show ipv6 mld snooping mrouter
Displays MLD Snooping interface information, interface filtering profiles and maximum number of groups that a port can join.	show ipv6 mld snooping interfaces <i>interface-type interface-name</i>
Displays multicast information about a single VLAN, on which MLD Snooping is configured.	show ipv6 mld snooping vlan <i>vid</i>
Displays an MLD Profile.	show ipv6 mld profile <i>profile-number</i>

MPLS Configuration

1. Configuring MPLS
2. Configuring BGP/MPLS IP VPN
3. Configuring MPLS GR
4. Configuring MPLS BFD

1 Configuring MPLS

i The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols.

1.1 Overview

Multiprotocol Label Switching (MPLS) supports multiple network layer protocols, for example, Internet Protocol (IP), IP version 6 (Ipv6), and Internetwork Packet Exchange (IPX). It is compatible with multiple link layer technologies, for example, asynchronous transfer mode (ATM), frame relay, Ethernet, and Point to Point Protocol (PPP). Labels are attached to packets, and packets are forwarded based on labels. MPLS uses connectionless control plane and connection-oriented data plane, which adds connection-oriented attributes to connectionless IP networks. MPLS was originally intended to make routers forward data faster. With the development of hardware technologies and network processors, this advantage has faded. However, as MPLS integrates the Layer-2 switching technology with Layer-3 routing technology, it outperforms other technologies in solving problems of virtual private networks (VPNs) and traffic engineering (TE). MPLS VPNs get increasingly popular among carriers in regard to enterprise interconnection and new services, becoming an important means by which carriers provide value-added services on IP networks. MPLS TE also has become an important means of managing network traffic, reducing congestion, and ensuring the QoS of IP networks. Therefore, MPLS is attracting more and more attention and increasingly applied to VPNs and TE.

Protocols and Standards

RFC3032: MPLS Label Stack Encoding

RFC3036: LDP Specification

RFC4182: Removing a Restriction on the use of MPLS Explicit NULL

RFC 5283: LDP Extension for Inter-Area Label Switched Paths (LSPs)

1.2 Applications

Application	Description
Providing the MPLS VPN Service	The geographically different branches of a private network are connected through label switched paths (LSPs) to form a unified network.

1.2.1 Providing the MPLS VPN Service

Scenario

MPLS Layer-3 VPN can be implemented through Multiprotocol Label Switching (MPLS).

Figure 1-1 shows the application scenario of MPLS Layer-3 VPN.

Figure 1-1 Application scenario of MPLS Layer-3 VPN

Deployment

- Public tunnels are established in a backbone network through the Label Distribution Protocol (LDP).
- Multiple VPN routing and forwarding (VRF) tables are created to maintain VPN routing information.
- Multiprotocol Extensions for BGP (MP-BGP) and Border Gateway Protocol (BGP) extended attributes are configured to transmit VPN routing information and carry VPN attributes and labels.

1.3 Features

Basic Concepts

➤ MPLS Node

An MPLS node can identify the MPLS signaling protocol (control protocol), run one or more Layer-3 routing protocols (including static routing protocols), and forwards packets based on MPLS labels. Generally, an MPLS node is capable of forwarding original Layer-3 packets (for example, IP packets).

➤ Forwarding Equivalence Class (FEC)

FEC refers to the packets forwarded equivalently, for example, packets sharing the same destination address or prefix. Packets can be classified in different ways in different application scenarios. In an IP unicast routing scenario, packets can be classified by address prefix; that is, a route corresponds to an FEC. Packets of the same FEC will be processed equivalently on an MPLS network.

➤ Label

A label is a short identifier of a fixed length that takes effect locally. Labels are transmitted only between two adjacent label switching routers (LSRs) and thereby are valid only between the LSRs. One label categorizes one FEC. When arriving at the MPLS network ingress, packets will be classified into different FECs based on rules. Labels are encapsulated in packets, and the packets are forwarded based on labels on the MPLS network.

➤ LSR

As the core of an MPLS network, LSRs switch and distribute labels. As described in RFC3031, an LSR is also an MPLS node capable of forwarding original Layer-3 packets (for example, IP packets or IPv6 packets), which means LSRs are capable of forwarding IP packets on IP networks.

↘ Label Switching Edge Router (LER)

On the MPLS network edge, an LER classifies data flows entering the network into different FECs and requests labels. When data flows exit the network, the LER pops the labels to restore original packets. Therefore, an LER classifies data flows, maps labels, and removes labels.

↘ LSP

Data flows of an FEC are given definite labels on different nodes. Labels are switched on all nodes during data forwarding. Data flows pass through an LSP, which is a collection of LSRs. An LSP can be considered as a tunnel that passes through the core MPLS network.

↘ Next Hop Label Forwarding Entry (NHLFE)

An NHLFE is used to forward the data on the next hop of MPLS packets. An NHLFE includes the following content:

- The next hop of packets.
- Link layer encapsulation used to forward packets.
- Coding mode used to forward packet label stacks.
- Operations on packet label stacks.

↘ Incoming Label Map (ILM)

An ILM table is a label forwarding table. It maps each incoming label to a series of NHLFEs (multiple NHLFEs indicate multiple paths). ILM is used when an LSR forwards labeled MPLS packets.

↘ FEC-to-NHLFE (FTN)

Different from ILM, FTN maps each FEC to a series of NHLFEs (multiple NHLFEs indicate multiple paths). FTN is used when an LER receives unlabeled packets. The LER encapsulates labels into the packets and then forwards them.

↘ LDP Peers

The LDP instances on two label switching routers (LSRs) that exchange label binding messages are called LDP peers.

↘ LDP Sessions

An LDP session is established through the Transmission Control Protocol (TCP) between two LDP peers to exchange label binding messages.

Overview

Feature	Description
MPLS Labels and Forwarding	This section describes the principles of labeling and label forwarding.

Static MPLS LSP	This section describes the process of establishing a static LSP through MPLS.
LDP and Session	This section describes the process of establishing an LDP session.
LDP Session Protection	This section describes the LDP session protection feature.
LDP LSP	This section describes the process of establishing an LSP through LDP.
Inter-Domain LDP LSP	This section describes the inter-domain LDP LSP feature.

1.3.1 MPLS Labels and Forwarding

Working Principle

Label Structure

Figure 1-2 Coding structure of MPLS labels

As shown in the figure, a label contains four domains. The following describes the domains.

- Label domain

The label domain stores label values and contains 20 bits. A label value is the index value of the label forwarding table. The Internet Engineering Task Force (IETF) specifies 0 to 15 as retained label values and predefines them.

Retained label value	Definition
0	It indicates IPv4 explicit null labels. According to RFC3032, Labels 0 must appear on the stack bottom; routers pop the labels and then forward packets based on IP addresses. According to RFC4182, routers pop Labels 0 and then forward packets based on what follows the labels: if labels follow, routers forward packets based on labels; if IPv4 packets follow, routers forward them based on IP addresses.
1	It indicates router alert labels, which must not appear on the stack bottom. Packets with router alert labels must be processed by the local software module and forwarded based on the labels following router alert labels. However, before the packets are forwarded, router alert labels must be pushed into the stack again, which is similar to the Router Alert option of an IP packet. After this option is selected, the LSR will check the MPLS packets every hop.
2	It indicates IPv6 explicit null labels. According to RFC3032, Labels 2 must appear on the stack bottom; routers pop the labels and then forward packets based on IP addresses. According to RFC4182, routers pop Labels 2 and then forward packets based on what follows the labels: if labels follow, routers forward packets based on labels; if IPv6 packets follow, routers forward them based on IP addresses.
3	It indicates implicit null labels, which can be distributed through the label distribution protocol but never appear in the label stack of MPLS packets. When an LSR switches labels of MPLS packets, Labels 3 on the stack top will be popped rather than replaced. These labels will be used for "penultimate-hop popping (PHP)".

Retained label value	Definition
4 to 15	They will be retained by the IETF for future use.

- Exp domain

The Exp domain stores MPLS QoS information and contains three bits.

- S flag

It is a flag on the stack bottom and contains one bit. If there are multiple labels, the S flag of labels on the stack bottom will be set to 0 and others 1.

- Time To Live (TTL)

The TTL contains 8 bits, similar to that of IP packet headers. It can be copied from the TTL domain of IP packet headers (or IPv6 hop limit) when IP packets are labeled for the first time. The TTL value of outer (top) labels is decreased by 1 when labels are switched. The MPLS packets running on an ATM link are coded in a different way because they don't have a TTL domain. For more details, see RFC3032.

↘ Label Stack

One MPLS packet may have multiple labels, which constitute a label stack. Labels close to the link layer header are called stack-top labels, and labels close to the IP header are called stack-bottom labels. LSRs always switch labels based on stack-top labels. Each label contains 32 bits. The label stack allows one MPLS packet to have multi-layer labels, which allows MPLS to support the layered network system as well as LSP tunnels.

↘ Operations on Labels

The following describes the basic operations on labels by an MPLS node:

- Push (adding labels)

On the ingress LER, the node inserts labels between link layer header and network layer header; or transit LSRs add labels to the top of the label stack.

- Pop (popping labels)

On the egress LER, the node removes all labels to restore packets to IP packets; or transit LSRs remove stack-top labels to reduce label stack layers.

- Swap (switching labels)

The node replaces stack-top labels based on the ILM table during packet forwarding.

↘ Label Distribution Protocol

As a new network system, MPLS has its signaling protocol or "routing protocol". In the MPLS system, two LSRs must reach an agreement upon the meanings of labels attached to the data transmitted between them through LDP. An LSR notifies label binding to the other through LDP. MPLS has more than one LDP. MPLS uses independent distribution protocols, for example, LDP defined by IETF in RFC3036, and extends existing protocols through piggybacking to support label distribution, for example, MP-BGP and Resource Reservation Protocol (RSVP). In a simple topology, you can manually assign labels to LSRs and establish static LSPs. You can choose label distribution protocols based on scenarios.

➤ MPLS Network

Figure 1-3

An MPLS network consists of two basic elements: LSR and LER. As the core of an MPLS network, LSRs run the MPLS signaling protocol LDP and forward labeled packets. When packets enter the MPLS network, LERs classify them into different FECs, label them, encapsulate them into MPLS packets, and forward them. When packets exit the network, LERs remove the labels to restore original packets. On an MPLS network, labeled packets will be forwarded through the LSP established through LDP.

The MPLS system consists of forwarding unit (data plane) and control unit (control plane). The forwarding unit searches the label forwarding information base and then forwards packets. The control unit creates a label forwarding information base between connected MPLS device nodes and maintains the base. Each MPLS node must run one or more routing protocols (including static routing protocols) to exchange routing information with other nodes. From the perspective of the control plane, each MPLS node is an IP router. Similar to traditional IP routers, MPLS nodes use unicast routing protocols (including static routing protocols) to establish and maintain routing tables. However, traditional routers use routing tables to establish forwarding tables, while MPLS nodes use routing tables to exchange label binding messages with adjacent nodes for destination subnets. A protocol used to exchange label binding messages is called LDP.

➤ MPLS Forwarding

Figure 1-4 Process of forwarding penultimate-hop popping MPLS packets

The following uses the example of traditional IP routing to describe MPLS forwarding.

- All LSRs (including LERs) use traditional routing protocols, for example, Open Shortest Path First (OSPF) and Intermediate System to Intermediate System (IS-IS), to establish IP routing tables.
- LSPs are established through LDP based on IP routing tables.

- The ingress LER receives an IP packet, analyzes the IP packet header and maps it into an FEC, attaches L1 to the packet, and forwards the labeled packet to the next-hop LSR through the LSP.
- The LSR receives the labeled packet and finds the LSP based on the label on the stack top, replaces the label, and forwards the packet to the next-hop LSR through the LSP.
- Transit LSRs repeat the previous step.
- The penultimate-hop LSR receives the labeled packet and checks the label forwarding table. If the outgoing label is an implicit null label (3), the LSR pops the label and forwards the original IP packet to the LSR of the last hop. If the label is an explicit null label, the LSR replaces the outermost label with a Label 0 and forwards the packet to the LSR of the last hop.
- If the penultimate-hop LSR pops the label, the egress LER of the last hop will receive an original IP packet and forward the packet based on the IP routing table. If the penultimate-hop LSR does not pop off the label because it is an explicit null label, the last-hop label edge router (LER) will receive the packet with the label value of 0 and pop off the label before forwarding the packet through a lookup into the IP routing table.

▾ MPLS TTL Mode

After MPLS encapsulation and decapsulation, IP (or MPLS) packets can be processed in two TTL modes.

- TTL replication mode: It is a default mode. When Push operation is performed, the TTL of the pushed label is copied from the TTL domain of the existing IP or MPLS packet header to the TTL domain of the pushed label. When Pop operation is performed, the inner IP or MPLS packet TTL is copied back from the TTL domain of outer labels. When TTL replication is enabled, if the inner header TTL is smaller than the outer header TTL, the inner header TTL will not be copied or changed.
- TTL non-replication mode: The TTL will not be copied. **When Push operation is performed, the TTL of the pushed label is set to 255. When Pop operation is performed, the inner IP or MPLS packet TTL will not change.**

In TTL replication mode, LSRs that pass through the MPLS domain can be tracked by using Tracert on the Customer Edge (CE). In TTL non-replication mode, LSPs will be processed as one hop.

Related Configuration

▾ Enabling MPLS Forwarding Globally

- By default, MPLS forwarding is disabled globally.
- Run the **mpls ip** command in global configuration mode to enable devices to support MPLS forwarding. After MPLS forwarding is enabled, the devices implement label switching preferentially; when label switching fails, the devices switch to IP forwarding.

▾ Enabling Label Forwarding on an Interface

- By default, label forwarding is disabled on interfaces.
- Run the **label-switching** command to enable MPLS forwarding on the specified interface. When you enable label forwarding on an interface, adjust the interface's maximum transmission unit (MTU) based on the service type; otherwise, the transmission of large packets may be affected.

↘ Configuring the MPLS MTU of an Interface

- The MPLS MTU determines whether an MPLS packet needs to be fragmented before being sent. The length defined by the MPLS MTU includes the total length of the MPLS encapsulation layer and encapsulated layer (such as IP).
- By default, the MPLS MTU of an interface is the same as its MTU.
- Run the **mpls mtu** command to configure the MPLS MTU of an interface.

↘ Configuring MPLS Packet Fragmentation

- You can configure the processing mode for MPLS packets whose sizes exceed the MPLS MTU.
- By default, IP fragmentation is implemented. The IP packet fragments are encapsulated with the original label and forwarded along the LSP associated with this label.
- Run the **mpls ip fragment** command to configure MPLS packet fragmentation.

↘ Configuring the ICMP Error Packet Processing Mode

- Configure the processing mode for ICMP error packets that are generated during MPLS packet forwarding. ICMP error packets include those generated when MPLS time to live (TTL) times out.
- By default, ICMP error packets are forwarded along the LSP associated with the label stack.
- Run the **mpls ip icmp-error pop labels** command to configure packet processing based on the label quantity. If the number of labels on the stack is smaller than or equal to the specified label quantity, the ICMP error packet will be forwarded through a lookup into the IP routing table that contains the forwarding equivalence class (FEC) of the topmost label. If the number of labels on the stack is greater than the specified label quantity, the ICMP error packet will be forwarded along the LSP associated with the label stack.

↘ Configuring MPLS TTL Replication

- By default, TTL replication is applied to the packets that the local device sends and forwards.
- Run the **mpls ip ttl propagate { public | vpn }** command to control TTL replication on the local device when sending and forwarding packets.

1.3.2 Static MPLS LSP

You can enable MPLS forwarding through static configuration without LDP.

- i** As LDP is not required for static configuration, IPv4 routes are not required. Even if no IPv4 route is available, static LSPs will take effect if the physical network is accessible.

Working Principle

↘ Configuring Static FTN on the Ingress LSR

At the LSP ingress, you need to establish FTN entries for FECs; that is, you need to bind FECs with labels.

↘ Configuring Static ILM on Transit LSRs

On transit LSRs, you need to configure ILM forwarding entries to map incoming labels to outgoing labels.

↘ **Configuring Static ILM on the Penultimate-hop LSR**

As PHP will be enabled on the penultimate hop, ILM entries on the penultimate hop must be different from those on transit LSRs; that is, the outgoing label of ILM on the penultimate-hop LSR must be an implicit null label (3).

i For information on PHP, see related materials.

Related Configuration

↘ **Configuring Static FTN on the Ingress LSR**

- In global configuration mode, run the **mpls static ftn** command to configure static FTN.
- The ingress LSR must be configured with FEC to NHLFE (FTN) to forward IP traffic to an LSP.
- If you configure FTN with the outgoing label value of 3, you must configure IP routes with the same prefix to make FTN effective.

↘ **Configuring Static ILM on Transit LSRs**

- In global configuration mode, run the **mpls static ilm in-label** command to configure static ILM.
- Transit LSRs must be configured with incoming label map (ILM) to forward MPLS packets.
- It is recommended that the outgoing label value of 3 be configured on the penultimate-hop LSR so that the egress LSR can directly receive IP packets; otherwise, you need to configure ILM on the egress LSR.

1.3.3 LDP and Session

LDP is mainly used to exchange label binding messages between IP unicast routes and Martini Layer-2 VPN.

i This section describes how to establish LSPs on unicast routes.

LDP peer discovery and LDP session establishment are the prerequisites of LSP establishment.

Working Principle

↘ **LDP Router ID**

An LDP Router ID uniquely identifies an LSR in a domain. It is in the IPv4 address format. By default, the LDP Router ID is the same as the Router ID (LSR ID) and must be globally unique.

↘ **LDP Peer Discovery and Maintenance**

LDP periodically sends User Datagram Protocol (UDP) Hello packets to advertise its state and listens to Hello packets to discover LDP peers.

If LDP discovers an LDP peer but has not received a Hello packet from this peer for a period of time, LDP determines that the LDP peer is invalid. This period is called the Hello packet keep-alive period.

↘ **LDP Session Establishment and Maintenance**

When LDP receives a Hello packet from an LDP peer, it uses the transport address advertised by the Hello packet to set up a TCP connection and initializes message exchange through the connection to negotiate LDP session parameters, in order to establish an LDP session.

After the LDP session is established, the two LDP peers periodically send keepalive packets to monitor the TCP connection. If a peer has not received a keepalive packet from the other peer for a period of time, it determines that the TCP connection is invalid and closes the LDP session. This period is called the keepalive packet keep-alive period.

Related Configuration

↳ Enabling LDP Globally

- By default, LDP is disabled globally.
- Run the **mpls router ldp [vrf-name]** command in global configuration mode to enable LDP for a VRF instance and enter LDP configuration mode.

↳ Enabling LDP on an Interface

- By default, LDP is disabled on interfaces.
- Run the **mpls ip** command in interface configuration mode to enable LDP on an interface.

↳ Configuring an LDP Router ID

- By default, the LDP Router ID is the same as the Router ID.
- Run the **ldp router-id** command to modify the LDP Router ID.

↳ Configuring a Transport Address

By default, the transport address used by an LDP session is the same as the LDP Router ID.

Run the **transport-address** command to specify the primary address of an interface or an IP address as the transport address used by the LDP session on the interface.

You can configure the transport address in either of the following modes:

- Run the **mpls ldp transport-address** command in interface configuration mode.
- Run the **transport-address** command in LDP configuration mode to globally configure the transport address used by all LDP sessions.

↳ Configuring the Hello Packet Interval

- The default Hello packet interval used by the basic LDP discovery mechanism is 5s.
- You can change the Hello packet interval in the range from 1s to 65,535s in interface configuration mode.

↳ Configuring the Hello Packet Keep-Alive Period

- By default, the default Hello packet keep-alive period used by the basic LDP discovery mechanism is 15s.
- You can change the Hello packet keep-alive period in the range from 1s to 65,535s in interface configuration mode. If it is set to 65,535s, the keep-alive period is infinitely long.

↘ Configuring the Keepalive Packet Keep-Alive Period

- By default, the keep-alive period of keepalive packets sent through an interface is 45s.
- You can change the keep-alive period in the range from 15s to 65,535s. The keepalive packet interval is one-third of its keep-alive period.

↘ Configuring the Maximum PDU Size

- LDP entities exchange messages as protocol data units (PDUs). By default, the maximum PDU size is 4,096. You can change it in the range from 256 to 4,096.

↘ Configuring LDP MD5 Authentication

- You can configure MD5 authentication of TCP connections to improve LDP session security.
- By default, LDP MD5 authentication is not configured.
- Run the **neighbor ip-address password [0 | 7] pwd-string** command to configure MD5 authentication of the TCP connection with the specified address.

1.3.4 LDP Session Protection

Faulty links will seriously affect network convergence and aggregation because the Hello adjacency between associated interfaces for LDP sessions will be disconnected when links fail and thereby LDP sessions will be closed. When links recover from failures, LSRs need to establish LDP sessions and exchange label binding messages again, which reduces the efficiency of LDP convergence.

LDP session protection can protect LDP sessions between two directly connected LSRs and LDP over TE sessions, and accelerate LDP convergence in case of link failures, especially when failures last for only a short time.

Working Principle

After LDP sessions between two LSRs are protected, a target Hello adjacency will be established between the LSRs. When the link between them fails, if alternative paths exist, the target Hello adjacency will be maintained. When the link fails, the link Hello adjacency will be disconnected, but the target Hello adjacency will maintain LDP sessions. When the link recovers from failures, LSRs do not need to establish LDP sessions again, which improves the efficiency of LDP convergence.

Figure 1-5 LDP session protection

As shown in the figure, R1, R2, and R3 are interconnected with each other at the link layer with OSPF enabled. LDP is enabled between R1 and R2. A link Hello adjacency will be established between R1 and R2 so that LDP sessions will be established. To protect LDP sessions between R1 and R2, you can enable LDP session protection on R1 and R2. In this way, a target Hello adjacency will be established between R1 and R2.

When the link between R1 and R2 fails, the link Hello adjacency will be disconnected. However, the target Hello adjacency will be maintained because of another path R1-R3-R2. Therefore, LDP sessions will not be closed.

When the link recovers from failures, R1 and R2 do not need to establish LDP sessions or exchange label binding messages again.

Related Configuration

Configuring LDP Session Protection

- By default, LDP instance session protection is disabled.
- Run the **session protection** command to enable or disable LDP session protection.
- You can enable LDP session protection on the two LSRs engaged in an LDP session. If only one LSR supports LDP session protection, you can configure this function on this LSR and run the **discovery targeted-hello accept** command on the other LSR to receive and reply to target Hello packets (or run the **neighbor ip-address** command to specify the remote peer).

1.3.5 LDP LSP

The LDP LSPs described in this section are the LSPs that LDP establishes on IP unicast routes.

Working Principle

Process of Establishing an LSP

Establishing an LSP means binding FECs with labels and notifying the operation to the adjacent LSR. This process is implemented through LDP based on RFC3036.

After LDP sessions are established, two LSRs can exchange label messages to bind labels and establish LSPs for FECs.

Labels can be distributed in Downstream on Demand (DOD) mode and Downstream Unsolicited (DU) mode. In DOD mode, an LSR replies to a label binding message only when receiving a label request from the adjacent LSR. In DU mode, an LSR distributes labels to the adjacent LSR without receiving requests.

Labels can be controlled in independent mode and ordered mode. In independent mode, each LSR can notify its adjacent LSR of label-FEC binding. In independent DOD mode, an LSR can immediately reply to label mapping requests from an upstream LSR rather than wait for label mapping messages from the next hop. In independent DU mode, an LSR can notify label mapping whenever it is ready to switch labels for an FEC.

In ordered mode, an LSR distributes upstream the label bound with an FEC only when it receives the label mapping message from the next hop or when it is the egress for the FEC; otherwise, the LSR must wait for the label mapping message from a downstream LSR. In ordered DU mode, an LSR notifies label mapping to an upstream LSR only when it is the egress for an FEC or when it receives the label from a downstream LSR. If downstream LDP session labels are distributed in DOD mode, the LSR will send downstream the label request from an upstream LSR.

If a label mapping message is not from the next hop of an FEC or if the message does not match any FEC, the message can be processed based on the label retention mode.

In liberal label retention mode, FEC label binding learned from the neighbor is retained; in conservative label retention mode, FEC label binding learned from the neighbor is not retained.

In conservative label retention mode, there are only a few labels to be used and maintained; however, when routes change, label values need to be obtained again, which increases the response time. In liberal label retention mode, LSRs respond to route changes quickly; however, unnecessary labels need to be distributed and maintained.

↳ LSP Loop Control

A loop detection mechanism is required. Two methods are available to prevent a loop: maximum hop count and path vector.

Maximum hop count: The number of LSRs is included in a label binding message. It is increased by 1 when an LSR passes. When the number exceeds the specified maximum, it indicates that a loop occurs, and LSP establishment will be stopped.

Path vector: The LSR ID is recorded in the vector list of a label binding message when an LSR passes. When receiving a label binding message, an LSR checks whether its ID is recorded in the vector list. If the ID is not recorded, the LSR will add it to the list. If the ID is recorded, it indicates that a loop occurs, and LSP establishment will be stopped.

↳ Policy-Based Label Distribution Control

By default, LDP distributes labels to all valid Interior Gateway Protocol (IGP) routes, except BGP routes. In special cases, you may want to distribute labels only to specified routes or LDP peers to reduce labels and LSPs used, in order to alleviate device and network burden. To do this, you can configure label distribution policies to achieve either or both of the following effects:

- Distribute Label Mapping messages with corresponding FECs only to specified IP routes.
- Distribute Label Mapping messages only to specified LDP peers.

↳ Policy-Based Label Reception Control

By default, LDP receives all Label Mapping messages over LDP sessions in DU mode and DOD mode. If an LDP session is in DOD mode, LDP sends the peer Label Request messages with FECs indicating the peer as the next hop. You can configure reception policies to achieve the following effects:

- Only receive the Label Mapping messages with FECs mapped to the specified IP route from the specified peer.
- Only send the Label Request messages with the specified FEC to the specified LDP peer.
- Do not receive Label Mapping messages from the specified peer.
- Do not send Label Request messages to the specified peer.

Related Configuration

▾ Configuring the Label Distribution Control Mode

- By default, label distribution is controlled in independent mode.
- Run the **lsp-control-mode** command to configure the LDP label distribution control mode.

▾ Configuring the Label Distribution Mode

- By default, labels are distributed in DU mode.
- Run the **mpls ldp distribution-mode** command in interface configuration mode to configure the LDP label distribution mode on an interface.

▾ Configuring the Label Retention Mode

- By default, labels are retained in liberal mode.
- Run the **label-retention-mode** command to configure the label retention mode.

▾ Configuring Loop Detection

- By default, loop detection is disabled.
- Run the **loop-detection** command to configure loop detection.

▾ Configuring the Maximum Number of Hops

- Run the **mpls ldp max-hop-count** command in interface configuration mode to configure the maximum number of hops in loop detection. The value ranges from 1 to 255. The default value is 254.
- After loop detection is enabled, loop occurs if the number of hops traversed by an LDP message exceeds the threshold.

▾ Configuring the Maximum Number of LSRs in the Path Vector List

- Run the **mpls ldp max-path-vector** command to configure the maximum number of LSRs in the path vector list used for loop detection. After loop detection is enabled, loop occurs if an LSR detects that its LSR ID is contained in the path vector list or the number of LSR IDs in the path vector list exceeds the threshold. The default value is 254.
- Run the **mpls ldp max-path-vector** command in interface configuration mode to configure the maximum number of LSRs in the path vector list.

↘ Configuring the Label Release Message Propagation Mode

- When an FEC is invalid, LDP will send a label release message from upstream to downstream to revoke the label bound to the FEC. The label release message propagation mode determines whether each receiving LDP entity on an LSP propagates the label release message to the downstream.
- By default, the receiving LDP entity does not propagate the label release message to the downstream.
- Run the **propagate-release** command to configure the label release message propagation mode.

↘ Configuring Label Distribution Policies

- Run the **advertise-labels for host-routes** command to distribute labels only to the host routes with a 32-bit mask in VRF tables. By default, labels are distributed to host routes with various mask lengths.
- Run the **advertise-labels for bgp-routes** [**acl** *acl-name*] command to distribute labels to BGP routes. By default, LDP does not distribute labels to BGP routes.
- Run the **advertise-labels for default-route** command to distribute labels to default routes. By default, LDP distributes implicit null labels with the value of 3 to default routes.
- Run the **advertise-labels for acl** *prefix-access-list* [**to** *peer-access-list*] command to distribute labels only to FECs and LDP peers that meet access control list (ACL) rules.

↘ Configuring Label Reception Policies

- Run the **neighbor** *ip-address* **labels accept** *acl-name* command to configure label reception policies. By default, LDP receives label binding messages over all sessions.

↘ Configuring Explicit Null Label Distribution

- By default, LDP distributes implicit null labels to FECs with local devices as the egress (for example, direct routes).
- Run the **explicit-null** command to distribute explicit null labels to all direct routes or direct routes that meet specified ACL rules.

1.3.6 Inter-Domain LDP LSP

When an autonomous system (AS) is divided into multiple IGP areas, to downsize the routing table and improve the efficiency, you need to configure host route aggregation on area border routers (ABRs). You can establish an LSP across multiple IGP areas for the route through the inter-area LDP LSP technology.

Such LSP is established by extending the longest route match.

Working Principle

↘ Inter-area LSP

An inter-area LSP crosses multiple IGP areas of an AS.

↘ ABR

For OSPF, an ABR is a node connecting backbone areas to other areas; for IS-IS, an ABR is a node between Level 1 and Level 2.

i When an AS is divided into multiple IGP areas and host routes are aggregated on ABRs, you can enable the inter-area LDP LSP function to establish an LSP across multiple IGP areas for the host routes.

When the inter-area LDP LSP function is disabled, LDP forwards labels only to accurately matched routes and distributes label mapping messages to all LDP neighbors. When the function is enabled, if there is a route with the longest mask that is matched to the FEC in a label mapping message and the neighbor sending the label mapping message corresponds to the next hop of the route, LDP will add forwarding entries and distributes label mapping messages to LDP neighbors (based on FECs in received label mapping messages rather than FECs matched to the route with the longest mask in the routing table).

The following figure shows the process of establishing an inter-area LDP LSP.

Figure 1-6

Based on the figure, the following describes the process of establishing an inter-area LDP LSP.

- On ABR1, aggregated routes are notified to backbone areas. Both aggregated route (192.168.2.0/24) and host route (192.168.2.1/32) are available in the routing table of ABR1.
- PE1 sends ABR1 a label mapping message of the FEC 192.168.2.1/32.
- ABR1 sends P2 label mapping messages of FECs 192.168.2.0/24 and 192.168.2.1/32, respectively.
- Only the aggregated route 192.168.2.0/24 is available in the routing table of P2. P2 sends P3 the label mapping message of the FEC 192.168.2.0/24. As there is a route with the longest mask (192.168.2.0/24) that is matched to the FEC 192.168.2.1/32 and ABR1 corresponds to the next hop of the route, P2 also sends P3 the label mapping message of the FEC 192.168.2.1/32.
- P3 repeats the actions of P2.
- An inter-area LSP across P3, P2, ABR1, and PE1 (192.168.2.1/32) is established between Area 0 and Area 1.

This process is similar to the process in ordered DU mode (as only aggregate routes are available upstream, the inter-area LDP LSP technology is inapplicable to the DOD mode). The LSP established in this way is the shortest IGP path.

If the MPLS forwarding entries added based on the longest match principle need to be deleted because of label cancellation messages from a downstream device or deletion of the matched route with the longest mask, the label cancellation messages need to be sent upstream (whether label distribution is controlled in ordered or independent mode). The following figure shows the process of canceling an inter-area LSP.

Figure 1-7

If the matched route with the longest mask changes (a better route is available or the route is deleted), the routing platform will notify LDP to update or delete the MPLS forwarding entries added based on the longest match principle to improve the accuracy of LSPs.

Related Configuration

Configuring the Inter-Domain LDP LSP Feature

- By default, the inter-area LDP LSP function is disabled.
- Run the **inter-area-lsp** command to enable or disable the inter-domain LDP LSP feature.
- The inter-domain LDP LSP feature only takes effect for aggregated host routes. If a longest match ACL rule is configured for aggregated non-host routes, this rule will be invalid.

1.4 Configuration

Configuration	Description and Command	
Configuring MPLS Forwarding	(Mandatory) It is used to enable MPLS.	
	mpls ip	Enables MPLS forwarding globally.
	label-switching	Enables MPLS forwarding on an interface.
	(Optional) It is used to configure MPLS forwarding parameters.	
	mpls mtu	Configures the MPLS MTU of an interface.
	mpls ip fragment	Configures MPLS packet fragmentation.

Configuration	Description and Command	
	mpls ip icmp-error pop	Configures the processing mode for ICMP error packets that are generated during MPLS packet forwarding.
	mpls ip ttl propagate public	Configures MPLS TTL replication.
Configuring a Static MPLS LSP	 (Mandatory) It is used to enable MPLS.	
	mpls static ftn out-label nexthop	Configures static FTN.
	mpls static ilm in-label forward-action swap-label nexthop fec	Configures static ILM.
Configuring an LDP Session	 (Mandatory) It is used to establish an LDP session.	
	mpls router ldp	Enables LDP.
	mpls ip	Enables LDP on an interface.
	neighbor	Creates a remote LDP peer.
	discovery targeted-hello accept	Configures the reception of target LDP Hello packets.
	 (Optional) It is used to configure LDP session parameters.	
	ldp router-id interface loopback	Configures an LDP Router ID.
	mpls ldp transport-address	Configures the transport address used by the local LDP session on an interface.
	transport-address	Configures the transport address used by the local LDP session in global configuration mode.
	mpls ldp hello-interval	Configures the Hello packet interval on every interface.
	discovery targeted-hello	Configures the Hello packet interval or keep-alive period used by the extended LDP discovery mechanism.
	mpls ldp hello-holdtime	Configures the Hello packet keep-alive period on every interface.
	mpls ldp keepalive-holdtime	Configures the keepalive packet keep-alive period on an interface.
	targeted-session holdtime	Configures the keepalive packet keep-alive period used by the remote LDP session.
	mpls ldp max-pdu	Configures the maximum length of every LDP message.
neighbor ip-address password	Enables LDP MD5 authentication.	
route wait label-mapping seconds	Configures the waiting time for label mapping during route updating.	

Configuration	Description and Command	
Configuring LDP Session Protection	 (Mandatory) It is used to enable LDP session protection.	
	session protection	Configures LDP session protection.
Configuring an LDP LSP	 (Optional) It is used to establish an LDP LSP.	
	loop-detection	Enables loop detection.
	mpls ldp max-hop-count	Configures the maximum number of hops in loop detection on an interface.
	mpls ldp max-path-vector	Configures the maximum number of LSRs in the path vector list used for loop detection on an interface.
	propagate-release	Enables label release message propagation.
	lsp-control-mode	Configures the LDP control mode globally.
	mpls ldp distribution-mode	Configures the LDP label distribution mode on every interface.
	label-retention-mode	Configures the label retention mode.
	advertise-labels	Configures label distribution policies for FECs mapped to IP routes.
	neighbor <i>ip-address</i> labels accept <i>acl-name</i>	Configures LSRs to filter Label Mapping messages sent by specified LDP peers based on specified ACL rules.
explicit-null	Configures distribution of explicit null labels to all direct routes or direct routes that meet specified ACL rules, or configures distribution of explicit null labels to neighbors that meet specified ACL rules and implicit null labels to other neighbors.	
Configuring the Inter-Domain LDP LSP Feature	 (Mandatory) It is used to enable the inter-domain LDP LSP feature.	
	inter-area-lsp	Configures the inter-domain LDP LSP feature.

1.4.1 Configuring MPLS Forwarding

Configuration Effect

- Enable MPLS forwarding on all LSRs and corresponding interfaces traversed by an LSP. The device forwards packet labels first rather than IP packets. When label forwarding fails, the device forwards IP packets.

Notes

- Enable MPLS forwarding in global configuration mode and interface configuration mode.

Configuration

↘ Enabling MPLS Forwarding Globally

- (Mandatory) Perform this configuration in global configuration mode.
- (Mandatory) Perform this configuration in global configuration mode on every LSR traversed by an LSP, unless otherwise specified.

↘ Enabling MPLS Forwarding on an Interface

- (Mandatory) Perform this configuration in interface configuration mode.
- (Mandatory) Perform this configuration in interface configuration mode on every interface traversed by an LSP, unless otherwise specified.

↘ Configuring the MPLS MTU of an Interface

- (Optional) Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↘ Configuring MPLS Packet Fragmentation

- (Optional) Perform this configuration in global configuration mode.
- Perform this configuration on every LSR traversed by an LSP, unless otherwise specified. If MPLS packet fragmentation is not enabled, LSRs cannot forward large packets that exceed the MTU size. By default, MPLS packet fragmentation is enabled.

↘ Configuring the ICMP Error Packet Processing Mode

- (Optional) Perform this configuration in global configuration mode.
- This configuration is required only in special cases.

↘ Configuring MPLS TTL Replication

- (Optional) Perform this configuration in global configuration mode.
- Disable MPLS TTL replication on every LSR traversed by an LSP if you want to hide the MPLS network topology.

Verification

Run the **show mpls summary** command to display the list of interfaces enabled with MPLS forwarding.

Run the **show run** command to check whether the configuration takes effect.

Related Commands

↘ Enabling MPLS Forwarding Globally

Command	mpls ip
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Enabling MPLS Forwarding on an Interface**

Command	label-switching
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	MPLS interface commands can be run only on Layer-3 interfaces. Therefore, non-Layer-3 interfaces need to be converted into Layer-3 interfaces.

↘ **Configuring the MPLS MTU of an Interface**

Command	mpls mtu bytes
Parameter Description	bytes: Indicates the length of an MPLS packet, which ranges from 64 to 1,500 bytes by default.
Command Mode	Interface configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. The MPLS MTU must not exceed the size of transmitted packets. You can run the mpls mtu command to adjust the MTU in interface configuration mode. 2. After encapsulating MPLS packets, devices that support MPLS packet fragmentation will fragment the packets whose length exceeds the MPLS MTU based on the MPLS MTU. Devices that do not support MPLS packet fragmentation will discard the packets whose length exceeds the MPLS MTU.

↘ **Fragmenting MPLS Packets**

Command	mpls ip fragment
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. This command is valid for IP packets only. 2. On devices that support MPLS packet fragmentation, you can use the no form of this command to disable MPLS packet fragmentation. On devices that do not support MPLS packet fragmentation, this command is invalid.

↘ **Processing ICMP Error Packet**

Command	mpls ip icmp-error pop labels
Parameter	<i>labels</i> : Indicates the number of labels of packets to be processed.

Description	
Command Mode	Global configuration mode
Usage Guide	You can run this command to have packets processed based on the number of labels. If the number of labels exceeds the configured value, the device will forward the packets through the LSP of the label stack. If the number of labels is below or equal to the configured value, the device will forward the ICMP error packets based on the IP routing table of the FEC corresponding to stack-top labels.

↘ **Configuring MPLS TTL Replication**

Command	mpls ip ttl propagate public
Parameter Description	public: Enables or disables TTL replication for sent packets. vpn: Enables or disables TTL replication for forwarded packets.
Command Mode	Global configuration mode
Usage Guide	When TTL replication is enabled, if the inner header TTL is smaller than the outer header TTL, the inner header TTL will not be copied or changed.

Configuration Example

↘ **Configuring MPLS Forwarding**

Scenario Figure 1-8	
Configuration Steps	<ul style="list-style-type: none"> ● Configure MPLS forwarding on the ingress LSR. ● Configure MPLS forwarding on transit LSRs. ● Configure MPLS forwarding on the penultimate-hop LSR.
LER-A	<pre>Nodexon(config)# mpls ip Nodexon(config)# interface gigabitEthernet 2/2 Nodexon(config-if-GigabitEthernet 2/2)# label-switching Nodexon(config-if-GigabitEthernet 2/2)# end</pre>
LSR-B	<pre>Nodexon(config)# mpls ip Nodexon(config)# interface gigabitEthernet 2/1 Nodexon(config-if-GigabitEthernet 2/1)# label-switching Nodexon(config-if-GigabitEthernet 2/1)# exit Nodexon(config)# interface gigabitEthernet 2/2</pre>

	<pre>Nodexon(config-if-GigabitEthernet 2/2)# label- switching Nodexon(config-if-GigabitEthernet 2/2)# exit Nodexon(config)# end</pre>
LER-C	<pre>Nodexon(config)# interface gigabitEthernet 2/1 Nodexon(config-if-GigabitEthernet 2/1)# label- switching Nodexon(config-if-GigabitEthernet 2/1)# end</pre>
Verification	<p>Check whether MPLS forwarding is enabled in interface configuration mode on all routers.</p>
LER-A	<pre>A# show mpls summary Minimum label configured: 16 Maximum label configured: 1048575 Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space Gi2/2 0 Total number of mpls interface is 1</pre>
LSR-B	<pre>B# show mpls summary Minimum label configured: 16 Maximum label configured: 1048575 Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space Gi2/1 0 Gi2/2 0 Total number of mpls interface is 2</pre>
LER-C	<pre>C# show mpls summary Minimum label configured: 16</pre>

<pre>Maximum label configured: 1048575 Per label-space information: Label-space 0 is using minimum label: 16 and maximum label: 1048575 Label-Switching Interface: Interface Label space ----- - Gi2/1 0 Total number of mpls interface is 1</pre>
--

Common Errors

- MPLS forwarding is not enabled globally.
- LDP is not enabled in interface configuration mode.

1.4.2 Configuring a Static MPLS LSP

Configuration Effect

Establish a static LSP

Notes

- Enable MPLS forwarding in global configuration mode and interface configuration mode.
- When you configure static TFN with the label value of 3, configure IP routes with the same next hop for forwarding.

Configuration

↘ **Configuring MPLS Forwarding on All LSRs**

- Perform this configuration according to section 1.4.1 "Configuring MPLS Forwarding."

↘ **Configuring Static FTN on the Ingress LSR**

- (Mandatory) Perform this configuration in global configuration mode.

↘ **Configuring Static ILM on Transit LSRs**

- (Mandatory) Perform this configuration in global configuration mode.

Verification

Run the **show mpls forwarding-table** command to display MPLS entries.

Related Commands

↘ **Configuring Static FTN on the Ingress LSR**

Command	mpls static ftn <i>ip-address/mask out-label label nexthop interface nexthop-ip</i>
Parameter Description	<i>ip-address/mask</i> : Indicates the address of an FEC, namely the destination address. out-label label : Indicates the outgoing label of the FEC. The value ranges from 16 to 1048575, or is 3. nexthop interface-name nexthop-ip : Indicates the next hop of the FEC, including the next-hop outgoing interface and IP address.
Command Mode	Global configuration mode
Usage Guide	You can run this command to add an FTN entry to the global FTN table. Upon receipt of an IP packet, the device on which MPLS is enabled finds the next hop based on the destination address of the IP packet by following the longest match principle, and then forwards the label of the IP packet. This command is valid for FTN entries whose destination address and mask are 0 only when the default route is available in the IP routing forwarding table.

▾ Configuring Static ILM on Transit LSRs

Command	mpls static ilm <i>in-label in_label forward-action swap-label swap_label nexthop interface nexthop-ip fec ip-address/mask</i>
Parameter Description	<i>in_label</i> : Indicates the incoming label of an ILM entry. The value ranges from 16 to 1025. forward-action : Specifies the forwarding action of the ILM entry. <i>label</i> : Specifies the value of the outgoing label when swap-label action is performed. The value ranges from 16 to 1048575, or is 0 or 3. <i>vrf-name</i> : Specifies the VPN for the ILM entry (namely VRF) when pop-l3vpn-nexthop action is performed. <i>interface-name</i> : Specifies the egress when pop-l2vc-destport action is performed. nexthop interface-name nexthop-ip : Specifies the next hop, including the next-hop egress and IP address. fec : Indicates the FEC for which the ILM entry is created. <i>ip-address/mask</i> : Specifies a destination network based on the FEC format of global or Layer-3 VPN application. <i>vc_id</i> : Specifies a virtual circuit (VC) instance based on the FEC format of Layer-2 VPN application. <i>The value ranges from 1 to 2147483647.</i> <i>vc-peer-addr</i> : Indicates the address of a VC peer.
Command Mode	Global configuration mode
Usage Guide	You can run this command to add an ILM entry to the ILM table. Upon receipt of an IP packet, the device on which MPLS is enabled finds the next hop based on the IP packet label value by following the longest match principle, and then forwards the label.

Configuration Example

▾ Configuring a Static MPLS LSP Network

<p>Scenario Figure 1-9</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure MPLS forwarding and static FTN on the ingress LSR. ● Configure MPLS forwarding and static ILM on transit LSRs. ● Configure MPLS forwarding and static ILM on the penultimate-hop LSR.

Common Errors

- MPLS forwarding is not enabled globally.
- MPLS forwarding is not enabled in interface configuration mode.

1.4.3 Configuring an LDP Session

Configuration Effect

- Establish an LDP session between two LSRs to exchange label binding messages.

Notes

- A reachable IP route to the transport address used by the peer to establish an LDP session must exist.

Configuration

▾ Configuring IP Routes

- (Mandatory) Configure static routes in global configuration mode or configure routes through OSPF or other IGP protocols.
- For details, see the *Configuring IP Routes*.

▾ Configuring LDP

- (Mandatory) Perform this configuration on the two LSRs engaged in an LDP session.

▾ Configuring an LDP Router ID

- (Optional) Perform this configuration in config-mpls-router configuration mode.
- It is recommended that an LDP Router ID be configured on each of the two LSRs engaged in an LDP session to ensure stable and reliable LDP.

 You must configure the LDP Router ID in actual application; otherwise, if the Router ID is changed during protocol restart, some functions (such as LDP MD5 authentication using the Router ID) may fail.

▾ Configuring the LDP Capability on an Interface or Configuring the Remote Peer

- Enable the LDP capability in interface configuration mode if a local LDP session needs to be established.
- Configure the remote peer in config-mpls-router configuration mode if a remote LDP session needs to be established.

▾ Configuring a Transport Address

- (Optional) If no transport address is configured, the LDP Router ID is used as the transport address.
- Configure a global transport address in config-mpls-router configuration mode if a local LDP session needs to be established. If a neighbor requires a specified transport address, configure this address on the interface connected to the neighbor.
- This configuration is not required if a remote LDP session needs to be established.

▾ Configuring the Hello Packet Interval

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.

- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

▾ Configuring the Hello Packet Keep-Alive Period

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.
- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

▾ Configuring the Keepalive Packet Keep-Alive Period

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode if a local LDP session needs to be established.
- Perform this configuration in config-mpls-router configuration mode if a remote LDP session needs to be established.

▾ Configuring the Maximum PDU Size

- This configuration is required only in special cases.
- Perform this configuration in interface configuration mode.

▾ Configuring LDP MD5 Authentication

- You can configure LDP MD5 authentication on the two LSRs engaged in an LDP session to improve session security.
- (Optional) Perform this configuration in config-mpls-router configuration mode.

▾ Configuring the Waiting Time for Label Mapping During Route Updating

- This configuration is required only in special cases.
- (Optional) It is performed in global configuration mode.

Verification

- Run the **show mpls ldp discovery** command to display the LDP peer discovery state.
- Run the **show mpls ldp neighbor** command to display the LDP session state.
- Run the **show mpls ldp bindings** command to display the LDP label binding state.
- Run the **show run** command to check whether the configuration takes effect.

Related Commands

▾ Enabling LDP Globally

Command	mpls router ldp [vrf-name]
Parameter Description	<i>vrf-name</i> : Enables or disables LDP of a specified VRF instance.
Command Mode	Global configuration mode

Usage Guide	The number of LDP instances is limited by the number of VRF instances. Each VRF instance can enable one LDP instance. By default, LDP instances of global VRF instances are enabled (or disabled).
--------------------	---

↘ Configuring an LDP Router ID

Command	ldp router-id { <i>ip-address</i> interface <i>interface-name</i> [force] }
Parameter Description	<i>ip-address</i> : Specifies a static IP address as the LDP router ID. The ID takes effect immediately. <i>interface-name</i> [force]: Specifies the primary address of a specified interface as the LDP router ID. If force is specified, the ID must be forced to take effect immediately.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures an LDP router ID.

↘ Enabling LDP on an Interface

Command	mpls ip
Parameter Description	N/A
Configuration Mode	Interface configuration mode
Usage Guide	Enables LDP on an interface.

↘ Configuring a Remote LDP Peer

Command	neighbor <i>ip-address</i>
Parameter Description	<i>ip-address</i> : Indicates the ID of the peer LSR.
Configuration Mode	config-mpls-router mode
Usage Guide	Creates a remote LDP peer.

↘ Receiving Target Hello Packets Through LDP

Command	discovery targeted-hello accept [from <i>acl-name</i>]
Parameter Description	<i>acl-name</i> : Indicates the name of ACL rules. Only the target Hello packets from neighbors specified by ACL rules can be received.
Configuration Mode	config-mpls-router mode
Usage Guide	When remote peers of two devices are established, you can configure a neighbor at one end and enable this function at the other end. To delete a remote peer, you only need to delete the neighbor configuration.

↘ Configuring a Transport Address

Command	mpls ldp transport-address { interface <i>ip-address</i> }
----------------	--

Parameter	interface: An LDP session uses the primary address of an interface.
Description	<i>ip-address:</i> An LDP session uses the specified IP address.
Configuration Mode	Interface configuration mode
Usage Guide	This command is valid for local LDP sessions established by the basic LDP discovery mechanism and invalid for remote LDP sessions established by the extended LDP discovery mechanism. It is valid for new local LDP sessions and invalid for existing local LDP sessions.

Command	transport-address { interface <i>ip-address</i> <i>interface-name</i> }
Parameter Description	interface: A local LDP session uses the primary IP address of an interface as a transport address. <i>ip-address:</i> All local LDP sessions use a specified IP address as the transport address. <i>interface-name:</i> All local LDP sessions use the primary IP address of a specified interface as the transport address.
Configuration Mode	config-mpls-router mode
Usage Guide	This command is valid for local LDP sessions established by the basic LDP discovery mechanism and invalid for remote LDP sessions established by the extended LDP discovery mechanism. Remote LDP sessions always use the LDP LSR ID as the transport address. If transport addresses are configured in both global and interface configuration modes, the transport address configured in interface configuration mode is preferred.

▾ Configuring the Hello Packet Interval

Command	mpls ldp hello-interval <i>seconds</i>
Parameter Description	<i>seconds:</i> Indicates the Hello packet interval, which ranges from 1 to 65,535 seconds.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the LDP link Hello packet interval.

Command	discovery targeted-hello <i>interval seconds</i>
Parameter Description	<i>seconds:</i> Indicates the Hello packet interval, which ranges from 1 to 65,535 seconds.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the LDP target Hello packet interval.

▾ Configuring the Hello Packet Keep-Alive Period

Command	mpls ldp hello-holdtime <i>seconds</i>
Parameter	<i>seconds:</i> Indicates the Hello packet keep-alive period, which ranges from 1 to 65,535 seconds. 65,535

Description	seconds indicate that a timeout will never occur.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the link Hello packet keep-alive period.

Command	discovery targeted-hello <i>holdtime seconds</i>
Parameter Description	Indicates the target Hello packet keep-alive period, which ranges from 1 to 65,535 seconds. 65,535 seconds indicate infinite hold time.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the target Hello packet keep-alive period.

↘ Configuring the Keepalive Packet Keep-Alive Period

Command	mpls ldp keepalive-holdtime <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keep-alive packet keep-alive period, which ranges from 15 to 65,535 seconds.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the keep-alive packet keep-alive period for local LDP sessions in interface configuration mode.

Command	targeted-session holdtime <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the keep-alive packet keep-alive period, which ranges from 15 to 65,535 seconds.
Configuration Mode	config-mpls-router mode
Usage Guide	The default keep-alive packet keep-alive period is used for restoration of local LDP sessions.

↘ Configuring the Maximum PDU Size

Command	mpls ldp max-pdu <i>max-pdu</i>
Parameter Description	<i>max-pdu</i> : Indicates the maximum PDU length for message exchange, which ranges from 256 to 4,096 bytes.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum PDU length.

↘ Configuring LDP MD5 Authentication

Command	neighbor <i>ip-address</i> password [0 7] <i>pwd-string</i>
Parameter Description	<i>ip-address</i> : Indicates the transport address of the peer LSR. [0 7]: (Optional) 0 indicates a plaintext key; 7 indicates a cyphertext key. By default, a plaintext key is

TCP connection: 192.168.0.1.646 - 192.168.0.3.1102

State: OPERATIONAL; Msgs sent/rcv: 7/8; UNSOLICITED

Up time: 00:00:09

Graceful Restart enabled; Peer reconnect time (msecs): 300000

LDP discovery sources:

  Targeted Hello 192.168.0.3 -> 192.168.0.1, active, passive;

Addresses bound to peer LDP Ident:

192.168.1.1      192.168.0.1
```

Common Errors

- IPv4 unicast routing is incorrectly configured.
- LDP is not enabled globally.
- LDP is not enabled interface configuration mode (or a remote peer is not configured).

1.4.4 Configuring LDP Session Protection

Configuration Effect

Protect LDP sessions between two directly connected LSRs.

Notes

You can enable LDP session protection on the two LSRs engaged in an LDP session. If only one LSR supports LDP session protection, configure LDP session protection on this LSR and run the **discovery targeted-hello accept** command on the other LSR to enable it to receive and reply to target Hello packets (or run the **neighbor ip-address** command to specify the remote peer).

Configuration

📄 Configuring an LDP Session

- (Mandatory) Perform this configuration according to section 1.4.3 "Configuring an LDP Session."

📄 Configuring LDP Session Protection

- (Mandatory) Perform this configuration in config-mpls-router configuration mode.
- Enable LDP session protection on the two LSRs engaged in an LDP session (see "Notes"), unless otherwise specified.

Verification

- Run the **show mpls ldp parameters** command to check whether LDP session protection is enabled.
- Run the **show mpls ldp neighbor** command to check whether LDP session protection takes effect.

Related Commands

Configuring LDP Session Protection

Command	session protection [for acl <i>acl_name</i>] [duration { infinite seconds }]
Parameter Description	<p>for acl <i>acl_name</i>: Configures ACL rules. Only the LDP sessions of LDP neighbors whose LSR IDs meet ACL rules are protected.</p> <p>duration: Configures the duration of session protection. When links fail and cause a Hello adjacency without associated interfaces, session protection will be enabled, and a target Hello adjacency will maintain LDP sessions.</p> <p>infinite: The target Hello adjacency will maintain LDP sessions infinitely.</p> <p>seconds: Indicates the duration of session protection, which ranges from 30 to 2,147,483 seconds.</p>
Configuration Mode	config-mpls-router mode
Usage Guide	Enables LDP protection.

Configuration Example

Enabling LDP Session Protection Between LSRs

<p>Scenario Figure 1-12</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On all nodes, configure the interface IP address, configure OSPF, and enable LDP. ● Enable LDP session protection.
<p>R1</p>	<pre>Nodexon(config)# interface Loopback 0 Nodexon(config-if-Loopback 0)# ip address 10.10.10 255.255.255.255</pre>

```
Session Protection: TRUE

Targeted Session Keepalive HoldTime/Interval: 180/60 sec

Targeted Hello HoldTime/Interval: 90/10 sec

Nodexon# show mpls ldp neighbor detail

Default VRF:

    Peer LDP Ident: 20.20.20.20:0; Local LDP Ident: 10.10.10.10:0

    TCP connection: 20.20.20.20.1030 - 10.10.10.10.646

    State: OPERATIONAL; Msgs sent/recvd: 6/7; UNSOLICITED

    Up time: 00:00:15

    Graceful Restart disabled

    LDP discovery sources:

    Targeted Hello 10.10.10.10 -> 20.20.20.20, active, passive;

    Hold time: 45 sec, hello interval: 5 sec

    Addresses bound to peer LDP Ident:

    holdup time remaining: 60 seconds
```

1.4.5 Configuring an LDP LSP

Configuration Effect

Establish an LSP on IP unicast routes through LDP.

Notes

- LDP needs to use unicast routes existing in the network; therefore, IP unicast routes must be configured.

Configuration

↘ [Configuring MPLS Forwarding](#)

- (Mandatory) Configure MPLS forwarding according to the section "Configuring Basic PIM-SM Functions 1".

↳ Configuring LDP Sessions

- (Mandatory) Configure LDP sessions according to the section "Configuring LDP Sessions 1".

↳ Configuring Loop Detection

- (Optional) Perform this configuration in config-mpls-router configuration mode.
- If IP routes are statically configured instead of being generated by IGP, you are advised to enable loop detection on every LSR traversed by the LSP to avoid loop caused by misconfiguration.

↳ Configuring the Maximum Number of Hops

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↳ Configuring the Maximum Number of LSRs in the Path Vector List

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↳ Configuring the Label Release Message Propagation Mode

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↳ Configuring the LDP Label Distribution Control Mode

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↳ Configuring the LDP Label Distribution Mode

- Perform this configuration in interface configuration mode.
- This configuration is required only in special cases.

↳ Configuring the LDP Label Retention Mode

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

↳ Configuring Label Distribution Policies

- (Optional) Perform this configuration in config-mpls-router configuration mode.

i By default, LDP distributes labels only to IGP routes but not to BGP routes. To distribute labels to BGP routes, run the **advertise-labels for bgp-routes** command.

- By default, LDP distributes implicit null labels with the value of 3 to default routes; therefore, an LSP is not established on default routes.

Configuring Label Reception Policies

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

Configuring Explicit Null Label Distribution Policies

- Perform this configuration in config-mpls-router configuration mode.
- This configuration is required only in special cases.

- Explicit null label distribution policies can be configured only for global LDP instances but not for VRF instances.

Verification

- Run the **show mpls ldp discovery** command to display the LDP peer discovery state.
- Run the **show mpls ldp neighbor** command to display the LDP session state.
- Run the **show mpls ldp bindings** command to display the LDP label binding state.
- Run the **show mpls forwarding-table** command to display the LSP entry state.

Related Commands

Configuring Loop Detection

Command	loop-detection
Parameter Description	N/A
Configuration Mode	config-mpls-router mode
Usage Guide	Enables loop detection.

Configuring the Maximum Hop Count

Command	mpls ldp max-hop-count <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum hop count allowed for loop detection. The value ranges from 1 to 255.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum hop count for loop detection.

Configuring the Maximum Number of LSRs in the Path Vector List

Command	mpls ldp max-path-vector <i>number</i>
Parameter	<i>number</i> : Indicates the maximum number of of LSRs in the path vector list. The value ranges from 0 to 255.

Description	
Configuration Mode	Interface configuration mode
Usage Guide	Configures the maximum number of LSRs in the path vector list.

↘ Propagating Label Release Messages

Command	propagate-release
Parameter Description	N/A
Configuration Mode	config-mpls-router mode
Usage Guide	Propagates label release messages downstream.

↘ Configuring the LDP Label Distribution Control Mode

Command	lsp-control-mode { independent orderd }
Parameter Description	independent: Indicates the independent control mode. ordered: Indicates the ordered control mode.
Configuration Mode	The independent control mode is used.
Usage Guide	Configures the label distribution control mode.

↘ Configuring the LDP Label Distribution Mode

Command	mpls ldp distribution-mode { du dod }
Parameter Description	dod: Indicates the DOD distribution mode. du: Indicates the DU distribution mode.
Configuration Mode	Interface configuration mode
Usage Guide	Configures the label distribution mode.

↘ Configuring the LDP Label Retention Mode

Command	label-retention-mode { liberal conservation }
Parameter Description	liberal: Indicates the liberal label retention mode. conservative: Indicates the conservative label retention mode.
Configuration Mode	config-mpls-router mode
Usage Guide	Configures the label retention mode.

↘ Configuring Label Distribution Policies

Command	advertise-labels [for host-routes for bgp-routes [acl <i>acl_name</i>] for default-route for acl <i>prefix-access-list</i> [to <i>peer-access-list</i>]
----------------	---

Parameter Description	<p>for host-routes: Distributes labels to host routes (with a 32-bit mask) only.</p> <p>for bgp-routes [acl acl_ame]: Distributes labels to BGP routes. You can use the acl keyword to have labels distributed to eligible BGP routes only.</p> <p>for default-route: Distributes labels whose value is not 3 to default routes.</p> <p>for acl prefix-access-list: Specifies the route prefix.</p> <p>to peer-access-list: Specifies the neighbors to which label binding messages should be sent.</p>
Configuration Mode	config-mpls-router mode
Usage Guide	Configures label distribution policies for FECs mapped to IP routes. You can use the no form of this command to recover the default.

↘ **Configuring Label Reception Policies**

Command	neighbor ip-address labels accept acl-name
Parameter Description	<p><i>ip-address:</i> Indicates the ID of the peer LSR.</p> <p><i>acl-name:</i> Specifies the name of ACL rules.</p>
Configuration Mode	config-mpls-router mode
Usage Guide	Configures label reception policies.

↘ **Configuring Explicit Null Label Distribution Policies**

Command	explicit-null [for prefix_acl] [to peer_acl]
Parameter Description	<p>for prefix_acl: Specifies the address prefix of the direct route for replacing implicit null labels with explicit null labels.</p> <p>to peer_acl: Specifies the LDP peer for replacing implicit null labels with explicit null labels.</p>
Configuration Mode	config-mpls-router mode
Usage Guide	Distributes explicit null labels to all direct routes or to routes meeting ACL rules.

Configuration Example

↘ **Establishing an LDP LSP**

Scenario Figure 1-13	<p>192.168.100.0/24 LSRID 192.168.0.1 LSRID 192.168.0.2 LSRID 192.168.0.3 192.168.200.0/24</p> <p>192.168.1.2 192.168.2.2</p> <p>192.168.1.1 192.168.2.1</p> <p>LER-A LSR-B LER-C</p>
Configuration Steps	<ul style="list-style-type: none"> ● Enable MPLS forwarding globally. ● Enable LDP globally. ● Enable LDP on an interface. ● Configure an LDP Router ID.

Common Errors

- IPv4 unicast routing is incorrectly configured.
- MPLS forwarding is not enabled globally.
- LDP is not enabled globally.
- LDP is not enabled on an interface.
- Label forwarding is not enabled on an interface.

1.4.6 Configuring the Inter-Domain LDP LSP Feature

Configuration Effect

When an AS is divided into multiple IGP areas and host routes are aggregated on ABRs, establish an LSP across multiple IGP areas for the host routes.

Notes

- The inter-domain LDP LSP feature takes effect only when the free label retention mode is configured.
- The inter-domain LDP LSP feature is not applicable in DOD label distribution mode.

Configuration Steps

Configuring IGP

- (Mandatory) Perform this configuration according to the *Configuring OSPF* or *Configuring IS-IS*.

Enabling Area Border Routers (ABRs) to Aggregate Host Routes

- (Mandatory) Perform this configuration according to the *Configuring OSPF* or *Configuring IS-IS*.

Configuring MPLS Forwarding

- (Mandatory) Configure MPLS forwarding according to the section "Configuring Basic PIM-SM Functions 1".

Configuring LDP Sessions

- (Mandatory) Configure LDP sessions according to the section "Configuring LDP Sessions 1".

Configuring the Inter-Domain LDP LSP Feature

- (Mandatory) Perform this configuration in config-mpls-router configuration mode.
- After route aggregation, enable the inter-domain LDP LSP feature on every LSR traversed by the corresponding LSP.

Verification

- Display configurations of LDP instances to check whether the inter-area LDP LSP function is enabled.
- Check whether an MPLS entry is added to the route compliant with the longest match rule on every router.

Related Commands

Command	<code>inter-area-lsp [for acl acl_name]</code>
Parameter	<code>for acl acl_name</code> : Configures ACL rules and establishes inter-area LSPs for the aggregated host routes
Description	(with a 32-bit mask) that meet ACL rules only.
Configuration Mode	config-mpls-router mode
Usage Guide	Enables the inter-area LDP LSP function on all devices between PEs.

Configuration Example

Establishing an LSP (Across Different Areas) Between PE1 and PE2, and Enabling the Inter-area LDP LSP Function (OSPF Network)

```

Protocol version: 1

Ldp Router ID: 8.8.8.8

Control Mode: INDEPENDENT

Propagate Release: FALSE

Label Merge: TRUE

Label Retention Mode: LIBERAL

Loop Detection Mode: off

Inter Area Lsp: TRUE

Session Protection: FALSE

Targeted Session Keepalive HoldTime/Interval: 180/60 sec

Targeted Hello HoldTime/Interval: 90/10 sec

Nodexon# show mpls ldp bindings

Default VRF:

lib entry: 10.10.10.10/32

local binding: to lsr: 10.10.10.10:0, label: 1027

Displays LDP attributes.	show mpls ldp parameters [all vrf <i>vrf-name</i>]

Description	Command
Displays MPLS express forwarding.	show mpls ref ftn-ipv4 [global vrf <i>vrf_name</i>] [<i>ip_address / mask</i> [detail]] show mpls ref ftn-ipv6 [global vrf <i>vrf_name</i>] [<i>ipv6_address / mask</i> [detail]] show mpls ref ilm [in-label <i>label</i> [detail]] summary] show mpls ref nhlfe [[<i>nhlfe_id</i> [detail]]] summary] show mpls ref summary
Displays the routing information base (RIB).	show mpls rib [all vrf <i>vrf-name</i>] [ipv6]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs LDP session messages.	debug mpls ldp message
Debugs LDP label binding.	debug mpls ldp binding
Debugs internal processing of MPLS entries.	debug mpls
Debugs MPLS messages.	debug mpls msg [send recv]
Debugs the MPLS express forwarding control plane.	debug mpls ref control
Debugs MPLS express forwarding.	debug mpls ref packet
Debugs events during execution of the ping mpls or traceroute mpls command.	debug mpls lspv event
Debugs packets during execution of the ping mpls or traceroute mpls command.	debug mpls lspv packet
Debugs packet encapsulation TLV during execution of the ping mpls or traceroute mpls command.	debug mpls lspv tlv
Debugs errors during execution of the ping mpls or traceroute mpls command.	debug mpls lspv error

2 Configuring BGP/MPLS IP VPN

2.1 Overview

Conventional virtual private networks (VPNs) transmit private network data in public networks over tunneling protocols such as Generic Routing Encapsulation (GRE), Layer 2 Tunneling Protocol (L2TP), and Point-to-Point Tunneling Protocol (PPTP). BGP/MPLS IP VPN is a VPN implementation mode between L2TP and Layer 3 Tunneling Protocol (L3TP). Label Switched Paths (LSPs) are established in public networks over the Label Distribution Protocol (LDP) for Multiprotocol Label Switching (MPLS). MPLS VPN connects the geographically different branches of a private network over LSPs to form a unified network. MPLS VPN supports the interworking between different VPNs.

Carriers implement MPLS in IP backbone networks to provide the VPN service to users' private networks. MPLS allows users to build VPNs using routers instead of dedicated VPN devices. MPLS also allows carriers to scale VPNs easily.

i The router devices and router icons in this document represent general routers and Layer-3 switches that run routing protocols. Specific device forms are indicated by "router series products" or "switch series products".

2.2 Applications

Application	Description
Single-AS VPN Service Model	Carriers provide the VPN service to users' IP networks. Multiple sites of a user's VPN are connected to the same IP/MPLS autonomous system (AS).
Inter-AS VPN Service Model	Carriers provide the VPN service to users' IP networks. Multiple sites of a user's VPN are connected to different IP/MPLS ASs.

2.2.1 Single-AS VPN Service Model

Scenario

Carriers provide the MPLS VPN service to users' IP networks. Multiple sites of a user's VPN are connected to the same IP/MPLS AS and communicate with each other by exchanging VPN routes across the AS.

In Figure 2-1, two sites of VPN1 are connected to the same IP/MPLS AS.

Figure 2-1

Deployment

- Provider edge (PE) 1 and PE2 communicate with the provider (P) device over the Open Shortest Path First (OSPF) and Label Distribution Protocol (LDP), in order to implement the MPLS public network function.
- The customer edge (CE) devices communicate with the PE devices over OSPF, and the PEs communicate with each other over the Border Gateway Protocol (BGP), in order to implement OSPF access to MPLS L3VPN.
- The CEs communicate with the PEs over the Routing Information Protocol (RIP), and the PEs communicate with each other over BGP, in order to implement RIP access to MPLS L3VPN.
- The CEs communicate with the PEs over the Intermediate System to Intermediate System (IS-IS), and the PEs communicate with each other over BGP, in order to implement IS-IS access to MPLS L3VPN.
- The CEs communicate with the PEs over BGP, and the PEs communicate with each other over BGP, in order to implement BGP access to MPLS L3VPN.
- The CEs and the PEs exchange routes based on static configurations, and the PEs communicate with each other over BGP, in order to implement static access to MPLS L3VPN.

2.2.2 Inter-AS VPN Service Model

Scenario

Carriers provide the MPLS VPN service to users' IP networks. Multiple sites of a user's VPN are connected to different IP/MPLS ASs and communicate with each other by exchanging VPN routes across different ASs.

In Figure 2-2, two sites of VPN1 are connected to two IP/MPLS ASs.

Figure 2-2

Deployment

- The MPLS public network function is implemented between AS1 and AS2.
- Autonomous system boundary routers (ASBRs) 1 and ASBR2 are CEs that implement MPLS L3VPN over inter-AS Option A.
- The PEs communicate with each other over BGP to implement MPLS L3VPN over inter-AS Option B.
- The PEs communicate with each other over BGP to implement MPLS L3VPN over inter-AS Option C.

2.3 Features

Overview

Feature	Description
BGP/MPLS IP VPN Basic Functions	Uses legacy IPv4 backbone networks to provide the VPN service to users' IPv4 networks.
Inter-AS VPN Service Model	Provides the VPN service to users' IPv4 networks across multiple IPv4 backbone networks.
OSPF VPN Extended Attributes	Implements OSPF between PE and CE to simplify CE configuration and management.

2.3.1 BGP/MPLS IP VPN Basic Functions

Network Structure

CE, PE, and P play important roles in the BGP/MPLS VPN network structure, as shown in Figure 2-.

Figure 2-4

- CEs are located on the edge of user networks and belong logically to users' VPNs. A port on each CE is connected directly to a PE. A CE can be a router, switch, or host, and it may or may not support MPLS.
- PEs are located on the edge of the service provider (SP)'s backbone network and belong logically to the SP. A PE can be a router, ATM switch, or frame relay (FR) switch. PEs are connected directly to CEs, and one PE can be connected

to different CEs. PEs receive VPN information from CEs, send VPN information to other PEs, receive VPN information from other PEs, and distribute the received VPN information to corresponding CEs. PEs must support MPLS.

- The P router is the core device of the SP's backbone network. The P router implements routing and fast forwarding. It is not connected to CEs. The P router must support MPLS. It knows the route for any destination in the backbone network, but does not know the routes destined for the VPNs.

Application Features

- VPN tunnels are established on the SP's PEs, rather than on users' CEs. VPN routes are exchanged between PEs. Users do not need to maintain VPN information.
- Existing routing protocols are used to dynamically establish VPN tunnels and advertise routes, making it easy to scale VPNs.
- The use of overlapping addresses is supported, allowing different VPN users to use the same address space.
- VPN service content is exchanged by label switching rather than route distribution in the SP's network.
- VPNs deliver security comparable to that of leased lines.

Implementation

Mechanism

- LSP tunnels are established over LDP in the backbone network. (This process is completed when the SP's network topology is stable.)
- Packets are forwarded according to their labels and the local mapping table.
- MP-BGP and BGP extended attributes are used to transmit VPN routes and carry VPN attributes, labels, and other content.
- VPN routes are managed by creating multiple routing tables, maintaining VPN routes, and other methods.

VRF

A VPN routing and forwarding (VRF) table is used to solve local route conflicts.

Each PE-CE connection must be associated with a VRF table. A PE may have multiple VRF tables used to exchange routes with CEs. Each VRF table can be considered as a virtual router, which is connected to a CE and receives routes from the CE or advertises VPN routes to the CE. VRF tables allow PEs to support different VPNs that use the same address space without causing local route conflicts.

A VRF table consists of:

- An independent routing table
- A set of interfaces that belong to the VRF table
- A group of routing protocols only used by the VRF table

RD

A route distinguisher (RD) is an important attribute of VPN routes and used to solve route conflicts during the transmission process.

When routes are advertised over BGP in the backbone network to different VPNs with overlapping addresses, BGP selects the best route among those addresses for advertising; as a result, some VPNs cannot receive corresponding routes. To address this problem, different RDs are added to the overlapping addresses, allowing BGP, when making routing decisions, to distinguish those addresses according to the different RDs carried in VPN routes. In this way, all VPNs receive respective routes. RDs are only used to distinguish identical network addresses, and they are not required when different VPNs do not have overlapping addresses.

A unique RD is assigned to one VPN, so that different VPNs have different RDs to ensure normal transmission of routes over the backbone network. RDs are defined in the format of XX: XX, for example, RD 1: 100, in which 1 is an AS number in the backbone network and 100 is a user-assigned number. A VPN route carries only one RD.

An RD consists of the **Type** field, an Administrator sub-area, and an Assigned Number. Depending on the value of the **Type** field, the RD is encoded in one of the following three formats:

Figure 2-5 RD Structure

- When **Type** is **0**, the Administrator sub-area uses a two-byte public AS number, and the Assigned Number has four bytes and is managed by the SP.
- When **Type** is **1**, the Administrator sub-area uses a four-byte global IPv4 address, and the Assigned Number has two bytes and is managed by the SP.
- When **Type** is **2**, the Administrator sub-area uses a four-byte AS number, and the Assigned Number has two bytes and is managed by the SP.

Route-Target

The route target (RT) is an important attribute of VPN routes and used to indicate a route selection method.

RT attributes are classified into the export RT attribute and the import RT attribute. When a PE receives a VPN route from a CE, the PE adds the export RT attribute to the VPN route and advertises the route to the peer PE. When receiving a route from the peer PE, the PE determines whether to import the route to a VRF table according to the import RT attribute. The import principle is as follows: The PE imports the incoming VPN route to a VRF table only when the VPN route has an RT

attribute the same as the import RT attribute of the VRF table. In this way, the distribution of VPN routes is controlled flexibly. A VPN route can carry multiple RT values.

The BGP extended community attribute defines the RT encoding structure, as shown in Figure 2-

Figure 2-5 RT Structure

The RT is defined in a way similar to the RD. The RT with **Type** set to 0x02 or 0x202 must have a public AS number. The RT with **Type** set to 0x102 must have a global IPv4 address.

MP-BGP

VPN routes are transmitted over BGP in the backbone network, and carry the export RT attribute according to the BGP extended community attribute.

The traditional BGP4 protocol only transmits IPv4 routes. BGP must be extended for transmitting RD-included VPN routes. BGP is highly scalable and supports the definition of new attributes. Multi-Protocol BGP (MP-BGP) introduces new attributes based on BGP to support multiple protocols. MP-BGP can carry VPN routing information in the format of RD+IP address prefix. When receiving IPv4 routes from VPN users, MP-BGP adds RDs to the IPv4 routes to convert the routes into VPN-IPv4 routes, and then transmits the VPN-IPv4 routes between PEs in the backbone network.

2.3.2 Inter-AS VPN Service Model

Inter-AS VPN allows different sites of a user's VPN located in different ASs to communicate with each other by exchanging VPN routes across those ASs.

RFC4364 proposes the following three inter-AS VPN solutions:

- Option A: VRF-to-VRF mode
- Option B: single-hop MP-EBGP mode
- Option C: multi-hop MP-EBGP mode

2.3.2.1 Option A: VRF-to-VRF Mode

The Option A (VRF-to-VRF) solution is easy to implement. The ASBRs in ASs create a VRF table for every VPN that requires inter-AS communication, and bind an interface to each VRF table. The VRF tables between ASBRs use their bound interfaces to exchange VPN routes.

The purposes of creating VRF tables and binding interfaces are:

- To receive VPN routes in the local AS

- To set up EBGP connections between VRF tables in different ASs to exchange IPv4 routes.

Figure 2-7 VRF-to-VRF Inter-AS VPN

In Figure 2-7, the VRF tables between the two ASBRs establish an EBGP session to exchange IPv4 routes, and the ASBRs and the PEs establish an MP-IBGP session to exchange VPN routes. The VRF tables engaged in the EBGP session consider the peer as a CE. VRF-to-VRF configuration is similar to intra-AS configuration, requiring to establish an MP-IBGP session between ASBR and PE to exchange VPN routes and establish an EBGP session between VRF tables on different ASBRs in BGP VRF address family configuration mode to exchange IPv4 routes.

Features and Limitations

The Option A (VRF-to-VRF) solution is easy to implement and deploy over MP-IBGP. However, ASBRs must configure and bind an interface (a logical sub-interface) to every VPN that requires inter-AS communication. The number of bound interfaces must be at least equal to the number of the VPNs. In addition, VPNs must be configured one by one on the ASBRs. This causes scalability issues. The creation of sub-interfaces for individual VPNs also poses additional requirements on ASBRs. Therefore, the Option A solution is applicable to networks with few VPNs that require inter-AS communication.

- i** Option A configuration is similar to BGP/MPLS VPN configuration. The configuration process is omitted in this document.

2.3.2.2 Option B: Single-hop MP-EBGP Mode

In the Option A solution, ASBRs must configure a VRF table for each VPN and bind an interface to the VRF table. This is because VPN routes can only be carried over MP-IBGP, but cannot be exchanged directly between EBGP peers. VRF configuration on ASBRs is not required if VPN routes can be exchanged directly between EBGP peers. The Option B solution extends MP-IBGP for direct distribution of VPN routes between ASBRs. The solution is also called single-hop MP-EBGP. Figure 2- shows the topology.

Figure 2-8 Option B Inter-AS VPN

Features and Limitations

The Option B solution removes the need to allocate sub-interfaces to sites of each VPN on ASBRs and the need to establish inter-AS LSPs. Instead, VPN routes are transmitted directly between single-hop MP-EBGP neighbors. Because VPN routes are stored and propagated by ASBRs between ASs, the ASBRs are under great burden when handling a large amount of VPN routes. The ASBRs also need to forward public IP packets. This poses high requirements on ASBRs. Because ASBRs disable the RT filter function for handling incoming VPN routes, the VPN routes on a PE may be propagated to the ASBR in a different AS, which may cause VPN route leakage. To address this problem, SPs that exchange VPN routes must implement a confidence-based routing protocol, enabling ASBRs to trust each other and implement route filtering policies. The Option B solution is applicable to networks with many VPNs that require inter-AS communication.

Implementation

The Option B solution is implemented by the following methods:

- The ASBR retains the next hop in incoming VPN routes.
- The ASBR changes the next hop in incoming VPN routes.

The two methods are described in the following.

Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR sends the VPN route with the next hop unchanged to its MP-IBGP neighbors in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session, and two ASBRs exchange VPN routes directly over an MP-EBGP session. Because the ASBR does not change the next hop in the VPN route received from the MP-EBGP peer, the PEs (MP-IBGP neighbors) in the local AS must have the route destined for the next hop (an ASBR in the other AS). To do this, the ASBR redistributes this route to IGP in the local AS, in order to make the destination ASBR reachable. Then an LSP is established over LDP.

The configuration procedure is as follows:

1. Configure PEs and CEs to exchange routes.
2. Configure IGP and MPLS signaling for ASs.

3. Disable the default RT filter function on ASBRs.
4. Configure the PEs and the ASBR in the same AS to exchange VPN routes.
5. Configure ASBRs to establish an MP-EBGP session.
6. (Optional) Configure a route map for filtering VPN routes.
7. Configure IGP redistribution of the route destined for the ASBR in the other AS.

📌 Method 2: The ASBR Changes the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR changes the next hop in the incoming VPN route before sending the route to PEs in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session. The two ASBRs in different ASs exchange VPN routes over an MP-EBGP session. When receiving a VPN route from one ASBR, the other ASBR changes the route's next hop to itself before sending the route to MP-IBGP peers in the local AS.

The configuration procedure is as follows:

1. Configure PEs and CEs to exchange routes.
2. Configure IGP and MPLS signaling for ASs.
3. Disable the default RT filter function on ASBRs.
4. Configure the PEs and the ASBR in the same AS to establish an MP-IBGP session and enable the ASBR to change the next hop in incoming VPN routes to itself.
5. Configure ASBRs to establish an MP-EBGP session.
6. (Optional) Configure a route map for filtering VPN routes.

2.3.2.3 Option C: Multi-hop MP-EBGP Mode

The Option A and Option B solutions implement inter-AS VPN networking. A common feature of the two solutions is that ASBRs maintain and advertise VPN routes. ASBRs may become a bottleneck of network scalability when the ASBR in each AS needs to advertise a large amount of inter-AS VPN routes. The Option C (multi-hop MP-EBGP) solution is developed to address the scalability issue. The solution allows PEs in different ASs to exchange VPN routes directly over a multi-hop MP-EBGP session, removing the need for ASBRs to maintain and distribute VPN routes.

Figure 2-9 Multi-hop MP-EBGP

Features and Limitations

In multi-hop MP-EBGP mode, only PEs maintain VPN routes, whereas ASBRs do not store VPN user information. The configuration procedure is relatively complex. The solution is applicable to inter-AS VPN service provision in large scale.

Implementation

The Option C solution is implemented by the following methods:

- Enable IPv4 label distribution only between EBGP neighbors.
- Enable IPv4 label distribution between EBGP neighbors and between IBGP neighbors.

For Option C scalability, a route reflector (RR) is deployed in each AS, and the RRs between two ASs establish a multi-hop MP-EBGP session to exchange VPN routes. From the deployment perspective, Option C is also called the inter-RR multi-hop MP-EBGP solution.

The configuration of each Option C implementation method is described in the following.

Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors

In this implementation method, BGP routes must be redistributed using the IGP protocol (for example, OSPF or RIP) on ASBRs, so that each device in one AS has the route destined for each PE in the other AS. LSPs are established by distributing labels over LDP to the routes destined for PEs between ASs. IPv4 label switching is enabled between the directly connected inter-AS ASBRs. BGP assumes the role of MPLS signaling to distribute labels to the routes destined for PEs between ASs for LSP establishment.

The configuration procedure is as follows:

1. Configure PEs and CEs in each AS to exchange routes.
2. Configure IGP and MPLS signaling for ASs.
3. Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
4. Configure ASBRs to redistribute to IGP the routes of PEs that are learned over EBGP.
5. Configure a multi-hop MP-EBGP session.

Method 2: Enable IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors

As Method 1 enables IPv4 label switching only between EBGp neighbors, IGP and LDP in one AS need to maintain the routes destined for PEs in the other AS. That is, the inter-AS routes of PEs must be propagated to all devices between ASs. In actual application, for AS security consideration, the routes of PEs in one AS should not be propagated to each device in the other AS. Rather, the routes must be maintained only by BGP and transparent to IGP and LDP in the same AS. To meet this requirement, you can enable IPv4 label switching between EBGp neighbors and between IBGP neighbors.

Different from Method 1, Method 2 does not require IGP on ASBRs to redistribute BGP routes and does not require LDP to distribute labels to BGP routes. LDP is only responsible for LSP establishment in the local AS. However, IPv4 label switching must be enabled between IBGP neighbors and between EBGp neighbors for inter-AS LSP establishment, and PEs must support stacking of three consecutive labels.

The configuration procedure is as follows:

1. Configure PEs and CEs in each AS to exchange routes.
2. Configure IGP and MPLS signaling for ASs.
3. Configure PEs and ASBRs to establish an IBGP session in order to distribute labels to IPv4 routes.
4. Configure ASBRs to establish an EBGp session in order to distribute labels to IPv4 routes.
5. Configure a multi-hop MP-EBGP session.

2.3.3 OSPF VPN Extended Attributes

OSPF is typically used as an IGP internal routing protocol for users' VPNs in many application cases. No other routing protocols are required if OSPF is implemented between PE and CE, thus simplifying CE configuration and management.

The following describes the OSPF extended attributes between PE and CE.

Domain ID

A domain ID indicates the OSPF domain to which a route belongs. When an OSPF route for a VPN site that a CE learns is advertised as a type 1, 2, or 3 link-state advertisement (LSA) to a PE and redistributed to BGP to form a VPN route, the domain ID is also redistributed with the route to BGP and advertised as an extended community attribute of the VPN route. When the peer PE receives the VPN route and redistributes it to a VRF OSPF instance, the domain ID is also redistributed with the route to the VRF OSPF instance. If the VRF OSPF instance confirms that the domain ID of the route is the same as its domain ID, it advertises the route as an internal route to a CE. If the VRF OSPF instance confirms that the domain ID of the route is different from its domain ID, it advertises the route as an external route to the CE.

In Figure 2-3, CE1 advertises routes in the local OSPF domain as type 2 LSAs to PE1, which then forms VPN routes and advertises the routes to PE2. PE2 redistributes incoming routes to a VRF OSPF instance. Because the domain IDs of the VPN routes are the same as the domain ID of the VRF OSPF instance, the routes are advertised as internal routes to CE2.

Figure 2-3

DN Bit

The down-bit (DN bit) is used for loop detection between PE and CE running OSPF. Loops may occur when a PE advertises a learned VPN route to its connected VPN site and the VPN site transmits the route over OSPF to another connected PE, which then propagates the route.

In Figure 2-4, PE1 advertises the route `192.168.10.0/24` to PE2 and PE3. CE2 advertises the route to CE3 over OSPF, which then advertises the route to PE3. In this way, the route is redistributed to BGP on PE3, which preferentially selects OSPF for route redistribution and converts the route into a VPNv4 route before advertising the route. In this case, a loop may occur.

Figure 2-4

To avoid loops, PEs insert the DN bit as an optional field into type 3, 5, or 7 LSAs before advertising the LSAs to CEs. When other PEs receive LSAs containing the DN bit, OSPF on the PEs exclude the LSAs from OSPF route calculation.

VPN Route Tag

The VPN route tag provides another method of detecting loops between PE and CE running OSPF. When a PE and a CE communicate over OSPF, the corresponding VRF OSPF instance on the PE has a VPN route tag by default. When the VRF OSPF instance imports a VPN route and advertises it as a type 5 or 7 LSA to the CE, the LSA carries the VPN route tag. In an environment where one VPN site is connected to multiple PEs, when a PE receives a type 5 or 7 LSA that carries the same VPN route tag as that of its VRF OSPF instance, the LSA is excluded from OSPF route calculation.

Area Deployment

In normal cases, the link between a PE and a CE can be any OSPF area. If the PE-CE link is a non-0 area, the OSPF area where the CE is located considers the PE as an area border router (ABR). This may cause problems due to the following characteristics of OSPF with the ABR feature:

- The ABR calculates only type 3 LSAs of the backbone area.
- The ABR forwards only type 3 LSAs from the backbone area to other areas.

In Figure 2-, if the PE-CE link is a non-0 area, the PE redistributes the VPNv4 route advertised over MP-BGP to OSPF and restores the route to a type 3 LSA before advertising it to CE1. Because CE1 does not calculate LSAs of non-backbone areas, the type 3 LSA is not advertised to the router in Area0. As a result, VPN sites may fail to learn routes between each other. Therefore, non-0 areas between PE and CE must be deployed correctly.

Figure 2-16

In L3VPN application, if PEs and CEs exchange VPN routes over OSPF, you are advised not to deploy the backbone area at a VPN site. In the actual condition, if the backbone area has PEs as well as routers of a VPN site, at least one router series product of the VPN site must be connected to a PE, and the CE-PE link must belong to Area0. In this way, inter-area routes and external routes can be transmitted between the PEs and the VPN site.

Sham Link

A sham link is not an actual link, but a virtual link between the VRF tables on two PEs. Like OSPF links, sham links have OSPF interfaces and can be used to send OSPF packets, establish neighbor relationships, and send LSAs. When LSAs are flooded out over sham links, all OSPF route types remain unchanged, as shown in Figure 2-17.

Figure 2-17

The sham link established between VRF OSPF instances on different PEs have the following functions:

- The sham link transmits VPN routes to the peer PE over MP-IBGP, and original OSPF routes are imported on a best-effort basis on the peer PE. The sham link does not support real communication of OSPF topology information. An OSPF link is established over a sham link to connect OSPF instances of various sites and maintain complete topology information.
- Different sites of the same VPN exchange routes over the MPLS backbone network. These sites are connected by a backdoor link to support inter-site communication when the MPLS backbone network is not available. Two sites of a VPN that are located in the same OSPF area and connected by a backdoor link exchange routes over the MPLS backbone network as well as the backdoor link. Because the intra-AS routes exchanged over the backdoor link take precedence over the inter-AS routes exchanged over the MPLS network, routes of the two sites are forwarded preferentially over the backdoor link. This does not comply with the intention of VPN users connecting to the backdoor link. The sham link is introduced to ensure proper use of the backdoor link.

2.4 Configuration

! Interfaces used by BGP/MPLS IP VPN must be Layer-3 routing interfaces; otherwise, configuration fails.

Configuration	Description
Configuring BGP MPLS IP VPN Basic Functions	(Mandatory) It allows carrier networks to provide the single-AS VPN service.
Configuring the Inter-AS VPN Service Model: Option A	(Optional) It is applicable to carrier networks with light traffic of the inter-AS VPN service.
Configuring an Inter-AS VPN Service Model: Option B	(Optional) It is applicable to carrier networks with heavy traffic of the inter-AS VPN service.
Configuring an Inter-AS VPN Service Model: Option C	(Optional) It is applicable to carrier networks requiring large-scale VPN service provision.

Configuration	Description
Configuring OSPF VPN Extended Attributes	(Optional) It is applicable to VPN sites that run OSPF.

2.4.1 Configuring BGP MPLS IP VPN Basic Functions

Configuration Effect

Build the BGP/MPLS VPN service in a single AS.

Figure 2-17

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.
- The **mpls ip** and **label-switch** commands must be enabled on PEs' interfaces connected to a public network.

Configuration Steps

The configuration of BGP/MPLS VPN basic functions includes:

- (Mandatory) Configure an MPLS network.
- (Mandatory) Configure a VPN routing instance.
- (Mandatory) Configure PEs to exchange VPN routes.
- (Mandatory) Configure PEs and CEs to exchange routes.
- (Optional) Configure a method of VPN label distribution.
- (Optional) Configure VPN route import/export policies.
- (Optional) Configure static L3VPN FEC to NHLFE (FTN) and incoming label map (ILM).

📄 Configuring an MPLS Network

Before you implement MPLS in the backbone network, configure MPLS-specific LDP on the P and PE devices for public tunnel establishment. The configuration includes configuring LDP on corresponding MPLS devices and enabling MPLS packet forwarding on every interface.

Perform configuration on the P and PE devices according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# mpls ip	Enables MPLS globally.
Nodexon(config)# mpls router ldp	Configures LDP and enters LDP configuration mode.
Nodexon(config-mpls-router)# ldp router-id interface loopback id [force]	Configures the LDP router ID, which typically uses the IP address of a loopback interface.
Nodexon(config-mpls-router)# exit	Exits LDP configuration mode.
Ruijie(config)# interface type ID	Enters interface configuration mode.
Nodexon(config-if-type ID)# ip address ip-address mask	Configures the interface IP address.
Nodexon(config-if-type ID)# label-switching	Enables MPLS packet forwarding on the interface connected to the public network.
Nodexon(config-if-type ID)# mpls ip	Enables LDP on the interface.
Nodexon(config-if-type ID)# show running-config	Displays existing configurations.

📌 Configuring a VPN Routing Instance

VPN routing instances are also called VRF tables, which are configured on the PEs. The CEs and the P do not have VRF tables.

To configure a VRF table, you need to define the VRF table, configure RD and RT values for the VRF table, and associate the VRF table with an interface.

Perform configuration on the PEs according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# ip vrf vrf-name	Creates a VRF table and enters VRF configuration mode.
Nodexon(config-vrf)# rd rd-value	Configures an RD value.
Ruijie(config-vrf)# route-target { both export import } rt-value	Configures RT values.
Nodexon(config-vrf)# exit	Exits VRF configuration mode.
Nodexon(config-if-type ID)# interface type ID	Enters interface configuration mode.
Nodexon(config-if-type ID)# ip vrf forwarding vrf-name	Associates the VRF table with an interface.
Nodexon(config-if-type ID)# ip address address mask	Configures the interface IP address.
Nodexon(config-if-type ID)# show running-config	Displays existing configurations.

- ❗ After an RD value is defined or BGP VRF is enabled for a VRF table on a PE, the RD value cannot be modified or deleted. To modify the RD value, delete the VRF table, create a new one, and then set its RD value.
- ❗ The RD values of two different VRF tables on a PE must not be the same.
- ❗ After the **ip vrf forwarding vrf-name** command is executed, the IP address of the specified interface is deleted. You need to configure an IP address again in interface configuration mode.

↘ Configuring PEs to Exchange VPN Routes

To configure PEs to exchange VPN routes (not IPv4 routes) over BGP, enter VPN address family configuration mode to enable the capability of transmitting VPN routes to the peer PE.

Perform configuration on the PEs according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-num</i>	Creates BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>ip-address</i> remote-as <i>asn-number</i>	Configures a BGP session.
Ruijie(config-router)# neighbor <i>ip-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the MP-IBGP session.
Ruijie(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Nodexon(config-router-af)# neighbor <i>ip-address</i> activate	Activates the function of exchanging VPN routes over BGP.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

↘ Configuring PEs and CEs to Exchange Routes

Four methods are available for configuring the VRF tables on PEs and the CEs to exchange routes.

... Method 1: Implement BGP Between PE and CE

After a BGP session is established between PEs, establish a BGP session between PE and CE to connect all CEs over BGP. Redistribute VPN routes between CEs and BGP to build a fully meshed VPN.

Enter VRF address family configuration mode on the PEs and configure a BGP session between PE and CE according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>pe-asn-num</i>	Creates BGP and enters BGP configuration mode.
Nodexon(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Performs configuration and enters BGP VRF address family configuration mode.
Ruijie(config-router-af)# neighbor <i>ip-address</i> remote-as <i>ce-asn-num</i>	Establishes an EBGP session between PE and CE.

i If no RD value is defined for the specified VRF table, the system prompts that the RD value is not configured when you run the **address-family ipv4 vrf vrf-name** command, and you are not allowed to enter address family configuration mode under the VRF table.

Configure PE-CE BGP sessions on the CEs and introduce VPN routes to BGP according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>ce-asn-num</i>	Creates BGP and enters BGP configuration mode.
Ruijie(config-router)# neighbor <i>ip-address remote-as pe-asn</i>	Establishes an EBGP session between PE and CE.
Nodexon(config-router)# redistribute ospf <i>ospf-id</i>	Redistributes OSPF routes over BGP.
Ruijie(config-router)# exit	Exits BGP configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i>	Enters OSPF configuration mode.
Ruijie(config-router)# redistribute bgp subnets	Redistributes BGP routes over OSPF.
Ruijie(config-router)# exit	Exits OSPF configuration mode.

 Users' VPNs may run any dynamic protocols or use static routes. OSPF is used as an example.

... Method 2: Implement OSPF Between PE and CE

If users' VPNs run OSPF, connect PEs and CEs over OSPF, and no additional configuration is required on the CEs.

On the PEs, configure an OSPF instance for each VRF table connected to a CE, and use the OSPF instance to exchange routes with the CE. By redistributing BGP routes, OSPF transmits VPN routes received from the peer PE to the corresponding CE. By redistributing OSPF routes, BGP transmits to the peer PE the VPN routes that CEs send to the connected PE.

 OSPF must be enabled on the CEs' interfaces connected to the PEs, and no passive port (or other restrictions on route exchange) must be configured.

Perform configuration on the PEs according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# network <i>prefix mask area area-id</i>	Configures OSPF links.
Ruijie(config-router)# redistribute bgp subnets	Redistributes BGP routes over OSPF.
Ruijie(config-router)# exit	Exits OSPF configuration mode.
Nodexon(config)# router bgp <i>asn</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# address-family ipv4 vrf <i>vrf-name</i>	Enters BGP VRF configuration mode.
Nodexon(config-router-af)# redistribute ospf <i>ospf-id</i>	Redistributes OSPF routes.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

... Method 3: Implement RIP Between PE and CE

If users' VPNs run RIP, connect PEs and CEs over RIP, and no additional configuration is required on the CEs.

The VRF tables on PEs exchange routes with the CEs over RIP. By redistributing BGP routes, RIP transmits VPN routes received from the peer PE to the corresponding CE. By redistributing RIP routes, BGP transmits to the peer PE the VPN routes that CEs send to the connected PE.

- i** RIP must be enabled on the CEs' interfaces connected to the PEs, and no restrictions on route exchange must be configured.

Perform configuration on the PEs according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router rip	Creates an RIP instance and enters RIP configuration mode.
Ruiije(config-router)# address-family ipv4 vrf vrf-name	Enters RIP VRF address family configuration mode.
Nodexon(config-router-af)# version 2	Configures the RIP version number.
Ruiije(config-router-af)# network network-number [wildcard]	Configures RIP for CE-PE communication.
Ruiije(config-router-af)# redistribute bgp	Redistributes BGP routes over RIP.
Ruiije(config-router-af)# exit	Exits address family configuration mode.
Nodexon(config)# router bgp asn	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# address-family ipv4 vrf vrf-name	Enters BGP VRF configuration mode.
Nodexon(config-router-af)# redistribute rip	Redistributes RIP routes.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

... Method 4: Configure Static Routes Between PE and CE

Static routes are typically used in simple network environments.

Point static routes from PE to CE, and redistribute the static routes to BGP VRF tables. Point static routes from CE to PE, and introduce the static routes to users' VPNs.

Perform configuration on the PEs according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# ip route vrf vrf-name prefix mask interface-name nexthop	Configures static routes.
Nodexon(config)# router bgp asn	Enters BGP configuration mode.
Nodexon(config-router)# address-family ipv4 vrf vrf-name	Enters BGP VRF address family configuration mode.
Nodexon(config-router-af)# redistribute static	Redistributes static routes.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

- i** The configuration on the CEs is omitted.

↘ (Optional) Configuring a Method of VPN Label Distribution

The RFC4364 describes two label distribution methods for L3VPN: per-route label distribution and per-VRF label distribution. Per-route label distribution enables fast forwarding, whereby packets are forwarded to the next hop just by querying an ILM table. However, this method requires the maintenance of large-capacity ILM tables. Per-VRF label distribution allows all routes of a VRF table to share a label distributed to the VRF table, thus greatly reducing the ILM table capacity. However, this

method is less efficient at forwarding packets than per-route label distribution, because the former requires two table queries. The first query gets the VRF table to which the packet belongs from the ILM table, and the second query gets the packet forwarding route from the VRF table based on the destination IP address.

By default, L3VPN adopts per-VRF label distribution. You can run the **alloc-label** command in VRF configuration mode to change the default label distribution method, and you can also apply different label distribution methods to different VRF tables.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# ip vrf vrf-name	Creates a VRF table and enters VRF configuration mode.
Nodexon(config-vrf)# alloc-label per-vrf	Distributes a label to all routes of the VRF table. All VPN routes distributed over MP-BGP use the same label.
Nodexon(config-vrf)# alloc-label per-route	Distributes a label to each route of the VRF table. Each VPN route distributed over MP-BGP uses a different label.
Nodexon(config-vrf)# show running-config	Displays existing configurations.

-  When you change the label distribution method, MP-BGP cancels all VPN routes that have been advertised and re-advertises the routes.

(Optional) Configuring VPN Route Import/Export Policies

You need to define the import RT attribute in VRF configuration mode to specify which routes are imported to VRF tables, and define the export RT attribute to specify which RT attributes are carried in distributed routes. The import and export RT attributes take effect for all routes. In special application scenarios, you can control the import and export of VPN routes accurately based on policies.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# ip vrf vrf-name	Creates a VRF table and enters VRF configuration mode.
Nodexon(config-vrf)# import map routemap-name	Configures a policy for importing remote VPN routes to local VPN routes based on a route map.
Nodexon(config-vrf)# export map routemap-name	Sets the extended community attribute of the VPN routes distributed from the local end to the remote end based on a route map.
Nodexon(config-vrf)# show running-config	Displays existing configurations.

-  The rules defined by the **import map** command take effect following the import-specific extended community attribute defined in VRF configuration mode. That is, the VPN routes received from the remote end must have the extended community attribute defined by the **route-target import** command in VRF configuration mode before the routes are filtered based on the rules defined by the **import map** command.

➤ (Optional) Configuring Static L3VPN FTN and ILM

In normal cases, labels are distributed to VPN routes over MP-BGP, and public LSP tunnels are established over LDP in public networks. You can configure static LSPs for VPN label distribution and private LSP tunnel establishment.

... Configuring L3VPN FTN on PEs

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# mpls static l3vpn-ftn <i>vrf-name ip-address/mask out-label out-label remote-pe ip-address</i>	Configures a static private FTN, with the forwarding equivalence class (FEC) egress on the other PE. You need to specify a private label and the egress PE. The address of the egress PE is used for public LSP tunnel matching.
Nodexon(config)# mpls static l3vpn-ftn <i>vrf-name fec-prefix/fec-mask local-forward nexthop interface-name nexthop-ip</i>	Configures a static private FTN, with the FEC egress on the local PE. You need to specify the egress for the local PE and the next hop address. (The other VRF table is typically used as the outbound interface and the next hop.) This command is used when multiple VRF tables on the local PE belong to the same VPN.
Nodexon# show running-config	Displays existing configurations.

... Configuring L3VPN ILM on PEs

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# mpls static ilm in-label in-label forward-action pop-l3vpn-nexthop <i>vrf-name nexthop interface-name nexthop-ip-address fec ip-address/mask</i>	Configures L3VPN ILM on the PE. You need to specify the incoming label, outbound interface, and next hop address.
Nodexon# show running-config	Displays existing configurations.

- i** The static private FTN and ILM configurations take effect after the corresponding public LSP tunnel is established. For how to establish a public LSP tunnel, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions." You can establish a public LSP tunnel over LDP or based on static configuration.

Verification

- Run the **show mpls forwarding-table** command to display the corresponding MPLS entries.
- Check that VPN sites can communicate with each other.

Configuration Example

➤ Intranet Configuration

Scenario
Figure 2-18

Requirements: Two VPNs (VPNA and VPNB) exist. VPNA maintains sites at SiteA, SiteB, and SiteC, whereas VPNB maintains sites at SiteB and SiteC. Enable communication between users at different sites of VPNA and between users at different sites of VPNB, and disable communication between VPNA and VPNB.

Configuration Steps

- On PE1, configure a loopback interface, create a VRF table, define RD and RT values, and associate VPNA with the corresponding interface. Configure BGP, and establish an MP-IBGP session with PE2 and PE3 respectively. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE2 and PE3, configure a loopback interface, create two VRF tables named VPNA and VPNB, define RD and RT values, and associate the VRF tables with the corresponding interfaces. Configure BGP, and establish an MP-IBGP session with the neighboring PE. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- Configure VPNA-SiteA to establish an EBGP session with PE1. Configure VPNA-SiteB to establish an EBGP session with PE3. Configure VPNA-SiteC to establish an EBGP session with PE2. Configure VPNB-SiteB to establish an EBGP session with PE3. Configure VPNB-SiteC to establish an EBGP session with PE2.
- On P1 and P2, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

PE1

```
PE1# configure terminal

➤ **Centralized Isolation Control at the Internet Egress**

Scenario
Figure 2-21

The diagram illustrates a network topology for centralized isolation control at the Internet egress. It features three Provider Edge (PE) routers: PE1, PE2, and PE3. PE1 is centrally located and connected to both PE2 and PE3. PE2 is connected to VPN2, and PE3 is connected to VPN1. The Internet is connected to PE1 via a central router. PE1 has a loopback address of 1.1.1.1 and is connected to the Internet via Gi0/1.20. PE2 has a loopback address of 2.2.2.2 and is connected to PE1 via Gi1/1. PE3 has a loopback address of 3.3.3.3 and is connected to PE1 via Gi1/1. VPN1 and VPN2 are connected to PE2 and PE3 respectively via their respective interfaces. The Internet is connected to the central router via Gi0/1.10 and Gi0/1.20. The central router is connected to PE1 via Gi1/3. The diagram also shows various interfaces and addresses for each PE router and the central router.

Requirements: Disable inter-VPN communication, and configure VPNs to access the Internet over a single device. In Figure 2-, VPN1 and VPN2 must access the Internet over PE1, but the two VPNs are not allowed to communicate with each other.

Two isolation methods are available: centralized isolation control and distributed isolation control.

In centralized isolation control, to allow new VPN sites to access the Internet over a single egress, you only need to add filter rules on the egress CE, without the need to modify the configurations of other VPN sites. This method provides good scalability. The disadvantage is that the isolated traffic is discarded only on the

	<p>egress CE, which wastes network bandwidth.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE2, configure a loopback interface, create a VRF table named VPN2, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE2 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On CE2, configure the IP address of the interface connected to PE2, and configure the capability of exchanging routes with PE2 over OSPF. ● On PE3, configure a loopback interface and create a VRF table named VPN1. Assume that the export and import RT attributes of VPN1 are both 1: 200. Define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE3 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On PE1, configure a loopback interface and create a trunk interface. Create a VRF table named vrf_out, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a default route destined for the Internet. Create a VRF table named vrf_in, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE1 over EBGP. Configure an IBGP neighbor relationship with PE2 and PE3 respectively. Configure the route exchange function of the vrf_out VRF table. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On CE1, create sub-interfaces, configure an EBGP neighbor relationship with PE1, create an access control list (ACL), and configure ACL application on the Gi0/1.10 sub-interface. <p> This example uses the configuration of the switch virtual interface (SVI) and the 802.1Q sub-interface to describe how to connect PE1 and CE1. Some devices may not support the two interfaces. PE1 and CE1 can be connected by any two links (physical or logical) based on two routing adjacencies between them. You can select a suitable connection method according to the actual condition.</p>

↘ Distributed Isolation Control at the Internet Egress

Figure 2-22

Requirements: Disable inter-VPN communication, and configure VPNs to access the Internet over a single device. In Figure 2-, VPN1 and VPN2 must access the Internet over PE1, but the two VPNs are not allowed to communicate with each other.

Two isolation methods are available: centralized isolation control and distributed isolation control.

In distributed isolation control, to allow new VPN sites to access the Internet over a single egress, you need to add filter rules on the CEs for the original VPN sites that also access the Internet over the same egress. This method has poor scalability. The advantage is that traffic is discarded on the CEs for VPN sites, which saves network bandwidth.

Configuration Steps

- On PE1, configure a loopback interface, create a VRF table named vrf_net, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a default route destined for the Internet. Configure the capability of exchanging routes with CE1 over EBGP. Configure an IBGP neighbor relationship with PE2 and PE3 respectively. Configure the route exchange function of the vrf_net VRF table. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On CE1, configure an EBGP neighbor relationship with PE1.
- On PE2, configure a loopback interface, create a VRF table named VPN2, define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE2 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On CE2, create an ACL, configure ACL application on a sub-interface, configure the capability of exchanging routes with PE2, and configure a default static route.
- On PE3, configure a loopback interface and create a VRF table named VPN1. Assume that the export and import RT attributes of VPN1 are both 1: 200. Define RD and RT values, and associate the VRF table with the corresponding interface. Configure the capability of exchanging routes with CE3 over OSPF. Configure an IBGP neighbor relationship with PE1 for IP route distribution.

	<p>Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none">● On CE3, create an ACL, configure ACL application on a sub-interface, configure the capability of exchanging routes with PE3, and configure a default static route.

➤ **Multi-role Host Configuration**

Scenario
Figure 2-23

Common hosts can only access other hosts of the same VPN site, whereas multi-role hosts can access other hosts of multiple VPNs. In Figure 2-, PC1 and PC2 are located at a site of VPN1. PC2 is a multi-role host able to access the hosts at the sites of VPN1 and VPN2, whereas PC1 can only access hosts at the same site of VPN1.

Configuration Steps

- Configure an MPLS backbone network.
- Configure an MPLS L3VPN network.
- Configure a multi-role host to access the VRF tables named VPN_MR for VPN1 and VPN2 respectively, and advertise the route of the multi-role host to other VPNs.
- Configure policy-based routing (PBR) to redirect the access packets sent by the multi-role host to the VPN_MR VRF table.
- Configure a default route on CE1.

➤ MCE-based Hierarchy VPN Configuration

Scenario
Figure 2-24

A multi-VPN-instance customer edge (MCE) is deployed to reconstruct the single-plane MPLS L3VPN network into a hierarchical network. Figure 2- shows the network topology. The MCE stores the routes of the connected VPN sites and the default routes distributed by PE2, but does not store the routes of other VPN sites. This poses relatively low requirements on capacity and performance. PE1 and PE2 must store all VPN routes, which poses relatively high requirements on capacity and performance.

Configuration Steps

- (MPLS network configuration) Configure interface addresses and OSPF on PE1 and PE2, and configure the MPLS feature.
- (MPLS L3VPN network configuration) Configure CE-to-PE access on PE1, PE2, CE1, and CE2. Configure MP-IBGP on PE1 and PE2.
- Configure the MCE and the connected CEs.
- Configure default route distribution for the MCE.

PE1

```

PE1#configure terminal
PE1(config)#interface loopback 0
PE1(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255
PE1(config-if-Loopback 0)#exit
PE1(config)#interface GigabitEthernet 0/0
PE1(config-if-GigabitEthernet 0/0)#ip address 192.168.1.1 255.255.255.0
PE1(config-if-GigabitEthernet 0/0)#exit
PE1(config)#router ospf 1
PE1(config-router)#network 1.1.1.1 0.0.0.0 area 0
PE1(config-router)#network 192.168.1.0 0.0.0.255 area 0
PE1(config-router)#end
PE1#configure terminal
PE1(config)#mpls ip
PE1(config)#interface GigabitEthernet 0/0

.....
Success rate is 0 percent (0/5)
    
```

➤ Hierarchy VPN Configuration Based on BGP Routing Policies

<p>Scenario Figure 2-25</p>	 <p>BGP routing policies are implemented to reconstruct the single-plane MPLS L3VPN network into a hierarchical network. Figure 2- shows the network topology. PE1 and PE2 are lower-layer PEs that store only the routes of associated VPN sites and the default routes advertised by the upper-layer PEs. PE3 and PE4 are upper-layer PEs that store all VPN routes. PE3 is the upper-layer PE for PE1 and PE2.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● (MPLS network configuration) Configure interface addresses and OSPF on PE1, PE2, PE3, and PE4, and configure the MPLS feature. ● (MPLS L3VPN network configuration, with PE3 functioning as an RR) Configure CE-to-PE access on the PEs and CEs. Configure corresponding VRF tables on PE3, because PE3 needs to store VPN routes though it is not connected to any VPN site. Configure MP-IBGP on PE1, PE2, PE3, and PE4. ● Configure routing policies on PE3 to restrict VPN route advertisement to PE1 and PE2. ● Configure default VPN routes on PE3 and advertise the routes to PE1 and PE2 (do not advertise the routes to PE4). ● Configure VRF OSPF on PE1 and PE2 for default route advertisement.
<p>PE1</p>	<pre> PE1#configure terminal PE1(config)#interface loopback 0 PE1(config-if-Loopback 0)#ip address 1.1.1.1 255.255.255.255 PE1(config-if-Loopback 0)#exit PE1(config)#interface GigabitEthernet 0/0 </pre>

```

Common Errors

- The router ID does not consist of 32 bits, causing the failure to establish LDP and BGP neighbor relationships.

2.4.2 Configuring an Inter-AS VPN Service Model: Option A

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option A solution, the ASBR in each AS creates a VRF table for every VPN that requires inter-AS communication and binds an interface to the VRF table. The VRF tables between ASBRs exchange VPN routes over the bound interfaces.

Figure 2-26 VRF-to-VRF Inter-AS VPN

i The Option A solution requires that ASBRs configure and bind an interface (a logical sub-interface) to every VPN that requires inter-AS communication. The number of bound interfaces must be at least equal to the number of the VPNs. In addition, VPNs must be configured one by one on the ASBRs. This causes scalability issues. The creation of sub-interfaces for individual VPNs also poses additional requirements on ASBRs. Therefore, the Option A solution is applicable to networks with few VPNs that require inter-AS communication.

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.

- ASBRs must configure and bind an interface to every VPN that requires inter-AS communication.

Verification

- Verify that CE3 is pingable but CE2 and CE4 are unpingable from CE1.
- Verify that CE4 is pingable but CE1 and CE3 are unpingable from CE2.
- Verify that CE1 is pingable but CE2 and CE4 are unpingable from CE3.
- Verify that CE2 is pingable but CE1 and CE3 are unpingable from CE4.

Configuration Steps

For how to configure the Option A solution, see section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

Common Errors

No routing protocol is enabled between PE and CE if no VRF table is bound to an interface using the **ip vrf forwarding vrf_name** command. As a result, the **show ip route vrf vrf_name** command output does not contain any route at the CE end.

2.4.3 Configuring an Inter-AS VPN Service Model: Option B

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option B solution, a single-hop MP-EBGP session is established between ASBRs for direct distribution of VPN routes.

Figure 2-27 Option B Inter-AS VPN

- The Option B solution removes the need to allocate sub-interfaces to sites of each VPN and the need to establish inter-AS LSPs. Instead, VPN routes are transmitted directly between single-hop MP-EBGP neighbors. Because VPN routes are stored and propagated by ASBRs between ASs, the ASBRs are under great burden when handling a large amount of VPN routes. The ASBRs also need to forward public IP packets. This poses high requirements on ASBRs. Because ASBRs disable the RT filter function for handling incoming VPN routes, the VPN routes on a PE may be propagated to the ASBR in a different AS, which may cause VPN route leakage. To address this problem, SPs that

exchange VPN routes must implement a confidence-based routing protocol, enabling ASBRs to trust each other and implement route filtering policies. The Option B solution is applicable to networks with many VPNs that require inter-AS communication.

Notes

- The LDP router ID and BGP router ID must consist of 32 bits.
- ASBRs establish a single-hop EBGP session to exchange VPN routes. ASBRs may or may not change the next hop in VPN routes sent to the peer.

Implementation

The Option B solution is implemented by the following methods:

- The ASBR retains the next hop in incoming VPN routes.
- The ASBR changes the next hop in incoming VPN routes.

The two methods are described in the following.

2.4.3.1 Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR sends the VPN route with the next hop unchanged to its MP-IBGP neighbors in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session, and two ASBRs exchange VPN routes directly over an MP-EBGP session. Because the ASBR does not change the next hop in the VPN route received from the MP-EBGP peer, the PEs (MP-IBGP neighbors) in the local AS must have the route destined for the next hop (an ASBR in the other AS). To do this, the ASBR redistributes this route to IGP in the local AS, in order to make the destination ASBR reachable. Then an LSP is established over LDP.

Configuration Steps

- (Mandatory) Configure PEs and CEs to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Disable the default RT filter function on ASBRs.
- (Mandatory) Configure the PEs and the ASBR in the same AS to exchange VPN routes.
- (Mandatory) Configure ASBRs to establish an MP-EBGP session.
- (Optional) Configure a route map for filtering VPN routes.
- (Mandatory) Configure IGP redistribution of the route destined for the ASBR in the other AS.

↘ Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

▾ Disabling the Default RT Filter Function on ASBRs

By default, a PE rejects the VPN route received from the peer PE or an ASBR if the route is not imported to any of its VRF tables. To enable ASBRs to accept all VPN routes from other PEs or ASBRs without checking whether the VPN routes are imported to local VRF tables, you need to disable the RT filter function on ASBRs.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# no bgp default route-target filter	Disables the RT filter function.
Nodexon(config-router)# show running-config	Displays existing configurations.

▾ Configuring the PEs and the ASBR in the Same AS to Exchange VPN Routes

For details, see "Configuring PEs to Exchange VPN Routes" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

▾ Configuring ASBRs to Establish an MP-EBGP Session

Configure inter-AS ASBRs to establish a single-hop MP-EBGP session in order to distribute VPN routes.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>asbr-address</i> remote-as <i>asbr-asn-number</i>	Configures an EBGP session between ASBRs.
Nodexon(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Nodexon(config-router-af)# neighbor <i>asbr-address</i> activate	Enables the capability of exchanging VPN routes between peers.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

- i** To forward MPLS packets over the link between ASBRs, run the **label-switching** command to enable MPLS packet forwarding on the interfaces connected between the ASBRs.
- i** If ASBRs use the loopback interface address with a 32-bit mask (instead of a direct link address) as the source address for establishing an MP-EBGP session, do the following: (1) run the **neighbor ebgp-multi-hop** command to enable multi-hop EGBP; (2) configure a loopback static route destined for the peer end between ASBRs; (3) enable LDP or configure static FTN (set the outgoing label to 3, indicating that the ASBR is the penultimate hop).

▾ (Optional) Configuring a Route Map for Filtering VPN Routes

For AS security consideration, ASBRs are configured to send or receive only particular VPN routes based on specified policies. This security mechanism can be implemented using the RT extended community attribute for VPN route filtering. For ASBRs that disable the default RT filter function and therefore store all VPN routes, you can configure VPN routing policies to enable the ASBRs to receive only the inter-AS VPN routes from the PEs in the local AS, thus reducing the capacity burden on the ASBRs.

Configure filter policies in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# ip extcommunity-list standard <i>extcommunity-name extcommunity-number {permit deny} rt</i> <i>rt-value</i>	Creates an extcommunity attribute list.
Nodexon(config)# show ip extcommunity-list [<i>list-number list-name</i>]	Verifies the configured extcommunity attribute list.
Nodexon(config)# route-map route-map-name permit [<i>number</i>]	Creates a route map and enters route map configuration mode.
Nodexon(config-route-map)# match extcommunity <i>extcommunity-name extcommunity-number</i>	Configures RT matching rules for the route map.
Nodexon(config-route-map)# show route-map <i>route-map-name</i>	Displays the route map.
Nodexon(config-route-map)# exit	Exits route map configuration mode.
Nodexon(config)# router bgp as-num	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Nodexon(config-router-af)# neighbor peer-address route-map route-map-name in	Filters the VPN routes received from the ASBR in the other AS.
Nodexon(config-router-af)# neighbor peer-address route-map route-map-name out	Filters the VPN routes sent to the ASBR in the other AS.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

📌 Configuring IGP Redistribution of the Route Destined for the ASBR in the Other AS

If the ASBR in one AS retains the next hop in incoming VPN routes, the IBGP peers (PEs) in the AS learn the VPN routes with the next hop still being the ASBR in the other AS. Therefore, the PEs must learn the route destined for the next hop. On the ASBRs that establish a single-hop MP-EBGP session enabled with BGP label distribution to IPv4 or VPN routes, MP-BGP automatically generates a direct host route (with a 32-bit mask) destined for the peer ASBR and an FTN entry (the outgoing label is 3), so that the tunnel egress is not terminated on the local ASBR. To allow the PEs to learn the route destined for the ASBR in the other AS, you only need to configure the ASBR in the local AS to redistribute the route to local IGP.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router igp	Enters IGP (OSPF, RIP, or IS-IS) configuration mode.

Nodexon(config-router)# redistribute connected subnets	Redistributes the direct segment route.
Nodexon(config-router)# show running-config	Displays existing configurations.

Verification

- Verify that CE3 is pingable but CE2 and CE4 are unpingable from CE1.
- Verify that CE4 is pingable but CE1 and CE3 are unpingable from CE2.
- Verify that CE1 is pingable but CE2 and CE4 are unpingable from CE3.
- Verify that CE2 is pingable but CE1 and CE3 are unpingable from CE4.

Configuration Example

↘ **Inter-VPN Option B: Next Hop Unchanged**

<p>Figure 2-28</p>	<p>Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR1. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. ● On ASBR1, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with P1-AS1 and ASBR2 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP

	<p>address of the interface connected to ASBR2, and enable label forwarding on the interface.</p> <ul style="list-style-type: none"> ● On ASBR2, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with PE1-AS2 and ASBR1 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR1, and enable label forwarding on the interface.

Common Errors

- LDP sessions fail to be established, or the BGP RT filter function is not disabled. The direct subnet route is not redistributed to OSPF (that is, the **redistribute connected subnets** command is not executed); as a result, sites of CE-VPN1 are unpingable between each other.

2.4.3.2 Method 2: The ASBR Changes the Next Hop in Incoming VPN Routes

When an ASBR receives a VPN route from the peer ASBR in a different AS, the ASBR changes the next hop in the incoming VPN route before sending the route to PEs in the local AS. The PEs and the ASBR in the same AS exchange VPN routes over an MP-IBGP session. The two ASBRs in different ASs exchange VPN routes over an MP-EBGP session. When receiving a VPN route from one ASBR, the other ASBR changes the route's next hop to itself before sending the route to MP-IBGP peers in the local AS.

Configuration Steps

- (Mandatory) Configure PEs and CEs to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Disable the default RT filter function on ASBRs.
- (Mandatory) Configure the PEs and the ASBR in the same AS to establish an MP-IBGP session and enable the ASBR to change the next hop in incoming VPN routes to itself.
- (Mandatory) Configure ASBRs to establish an MP-EBGP session.
- (Optional) Configure a route map for filtering VPN routes.

↘ **Configuring PEs and CEs to Exchange Routes**

For details, see "Configuring PEs and CEs to Exchange Routes" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ **Configuring IGP and MPLS Signaling for ASs**

For details, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ **Disabling the Default RT Filter Function on ASBRs**

For details, see "Disabling the Default RT Filter Function on ASBRs" in section 2.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

↘ **Configuring the PEs and the ASBR in the Same AS to Establish an MP-IBGP Session and Enabling the ASBR to Change the Next Hop in Incoming VPN Routes to Itself**

By default, when receiving a VPN route from the MP-EBGP peer, an ASBR does not change the next hop in the VPN route but sends the route as it is to MP-IBGP peers. You can configure the ASBR to change the next hop to itself. In this way, the PEs in the local AS do not need to know the address of the ASBR in the other AS. Compared with Method 1, Method 2 requires the additional configuration of next hop change.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-num</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>pe-address</i> remote-as <i>asn-num</i>	Establishes an IBGP session with PEs.
Nodexon(config-router)# neighbor <i>pe-address</i> update-source <i>interface-name</i>	Specifies the local loopback interface as the source address for the IBGP session.
Nodexon(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Nodexon(config-router-af)# neighbor <i>pe-address</i> activate	Enables the capability of exchanging VPN routes between peers.
Nodexon(config-router-af)# neighbor <i>pe-address</i> next-hop-self	Configures the ASBR to change the next hop in incoming VPN routes to itself before sending the routes to IBGP peers.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

↘ **Configuring ASBRs to Establish an MP-EBGP Session**

For details, see "Configuring ASBRs to Establish an MP-EBGP Session" in section 2.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

↘ **(Optional) Configuring a Route Map for Filtering VPN Routes**

For details, see "Configuring a Route Map for Filtering VPN Routes" in section 2.4.3.1 "Method 1: The ASBR Retains the Next Hop in Incoming VPN Routes."

Verification

Run the ping command to check the connection between sites of the same VPN.

Configuration Example

Inter-VPN Option B: Next Hop Changed

<p>Scenario Figure 2-29</p>	 <p>Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR1. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure BGP, and establish an MP-IBGP session with ASBR2. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. On ASBR1, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish a neighbor relationship with PE1-AS1 and ASBR2 respectively. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface. Configure ASBR1 to change the next hop in VPN routes to itself before sending the routes to IBGP neighbors. On ASBR2, configure a loopback interface, configure BGP, and disable the BGP RT filter function. Establish neighbor relationships with PE1-AS2 and ASBR1. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes, and redistribute the direct segment route. Configure the IP address of the interface

	connected to ASBR1, and enable label forwarding on the interface. Configure ASBR2 to change the next hop in VPN routes to itself before sending the routes to IBGP neighbors.

Common Errors

- LDP sessions fail to be established, or the BGP RT filter function is not disabled. The ASBRs do not change the next hop in incoming VPN routes to itself before sending the routes to IBGP neighbors; as a result, sites of CE-VPN1 are unpingable between each other.

2.4.4 Configuring an Inter-AS VPN Service Model: Option C

Configuration Effect

Build the BGP/MPLS VPN service across ASs.

In the Option C solution, PEs in different ASs establish a multi-hop MP-EBGP session to directly exchange VPN routes.

Figure 2-5 Multi-hop MP-EBGP

-
- i** In multi-hop MP-EBGP mode, only PEs maintain VPN routes, whereas ASBRs do not store VPN user information. The configuration procedure is relatively complex. The solution is applicable to inter-AS VPN service provision in large scale.
-

Notes

- The LDP router ID must consist of 32 bits.
- The BGP router ID must consist of 32 bits.

Implementation

The Option C solution is implemented by the following methods:

- Enable IPv4 label distribution only between EBGP neighbors.
- Enable IPv4 label distribution between EBGP neighbors and between IBGP neighbors.
- Establish a multi-hop MP-EBGP session between RRs.

- i** For Option C scalability, an RR is deployed in each AS, and the RRs between two ASs establish a multi-hop MP-EBGP session to exchange VPN routes. From the deployment perspective, Option C is also called the inter-RR multi-hop MP-EBGP solution.
-

The configuration of each Option C implementation method is described in the following.

2.4.4.1 Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors

In this implementation method, BGP routes must be redistributed using the IGP protocol (for example, OSPF or RIP) on ASBRs, so that each device in one AS has the route destined for each PE in the other AS. LSPs are established by distributing labels over LDP to the routes destined for PEs between ASs. IPv4 label switching is enabled between the directly connected inter-AS ASBRs. BGP assumes the role of MPLS signaling to distribute labels to the routes destined for PEs between ASs for LSP establishment.

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure ASBRs to redistribute to IGP the routes of PEs that are learned over EBGP.
- (Mandatory) Configure a multi-hop MP-EBGP session.

↘ Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

📌 Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes

Establish an EBGP session between inter-AS ASBRs, and enable IPv4 label distribution. To introduce the routes of PEs to BGP, you can use the **network** command in BGP IPv4 address family configuration mode or the IGP redistribution command. For AS security consideration, IPv4 route distribution policies must be configured on ASBRs. You can define a route map to specify which routes are distributed to neighbors and whether the outgoing routes carry a label. Route maps can also be configured at the receive end.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp asn-num	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor asbr-address remote-as asbr-asn-num	Establishes an EBGP session between ASBRs.
Nodexon(config-router)# address-family ipv4	Enters BGP IPv4 address family configuration mode.
Nodexon(config-router-af)# neighbor asbr-address	Configures the function of exchanging labeled IPv4 routes with the peer ASBR in the other AS.
send-label Nodexon(config-router-af)# network pe-address mask mask	(Optional) Configures the addresses of the PEs in the local AS that require BGP routing table injection, that is, the host routes destined for the PEs in the local AS.
Nodexon(config-router-af)# neighbor asbr-address route-map routemap-name out	(Optional) Configures route distribution policies. You can define a route map to specify which routes are distributed to neighbors and whether the outgoing routes carry a label.
Nodexon(config-router-af)# neighbor asbr-address route-map routemap-name in	(Optional) Configures route distribution policies. You can define a route map to specify reception of only labeled routes.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

- ❗ To forward MPLS packets over the link between ASBRs, run the **label-switching** command to enable MPLS packet forwarding on the interfaces connected between the ASBRs.
- ❗ If ASBRs use the loopback interface address with a 32-bit mask (instead of a direct link address) as the source address for establishing an MP-EBGP session, do the following: (1) run the **neighbor ebgp-multi-hop** command to enable multi-hop EGBP; (2) configure a loopback static route destined for the peer end between ASBRs; (3) enable LDP or configure static FTN (set the outgoing label to 3, indicating that the ASBR is the penultimate hop).

In actual application, the ASBRs only need to distribute labels to the routes of PEs that carry the inter-AS VPN service. You can use the **set mpls-label** rule to enable such label distribution. This rule means setting a label for routes. You can create a route map to specify sending of only the inter-AS routes of PEs to the peer ASBR and set labels for those routes, and then run the **neighbor peer-address route-map rmap_name out** command in BGP IPv4 address family configuration mode to associate the route map.

The following example creates a route map, whereby MPLS labels are distributed to routes with the 1.1.1.1/32 prefix whereas ordinary IPv4 route updates instead of labels are distributed to routes with the 1.1.1.2/32 prefix. For routes that do not match ACL1 and ACL2, route updates are not sent to neighbors.

```
Router(config)# ip access-list standard acl1
Router(config-std-nacl)# permit host 1.1.1.1
Router(config-std-nacl)# exit
Router(config)# ip access-list standard acl2
Router(config-std-nacl)# permit host 1.1.1.2
Router(config-std-nacl)# exit
Router(config)# route-map out-as permit 10
Router(config-route-map)# match ip address acl1
Router(config-route-map)# set mpls-label
Router(config-std-nacl)# exit
Router(config)# route-map out-as permit 20
Router(config-route-map)# match ip address acl2
Router(config)# router bgp 100
Router(config-router)# neighbor 30.30.30.2 remote-as 100
Router(config-router)# neighbor 30.30.30.2 route-map out-as out
```

You can use the **match mpls-label** rule to specify reception of only labeled IPv4 routes. Configure a route map, and run the **neighbor peer-address route-map rmap_name in** command to associate the route map.

The following example creates a route map to specify reception of only labeled IPv4 routes from the BGP peer 30.30.30.2 while rejecting other routes.

```
Router(config)# route-map match-mpls
Router(config-route-map)# match mpls-label
Router(config)# router bgp 100
Router(config-router)# neighbor 30.30.30.2 remote-as 100
Router(config-router)# neighbor 30.30.30.2 route-map match-mpls in
```

📌 Configuring ASBRs to Redistribute to IGP the Routes of PEs That Are Learned over EBGp

When an ASBR learns from the peer ASBR the routes of PEs in the other AS, it needs to send the routes to the PEs in the local AS and establish an LSP destined for the PEs in the other AS. To do this, configure ASBRs to redistribute to IGP the

routes learned over EBGp, and enable LDP for distributing labels to BGP routes, in order to establish an LSP destined for the PEs in the other AS.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router igp	Enters IGP configuration mode.
Nodexon(config-router)# redistribute bgp subnets [route-map routemap-name]	Configures the protocol for BGP route redistribution. Route-map-based filtering is optional.
Nodexon(config-router)# exit	Exits IGP configuration mode.
Nodexon(config)# mpls router ldp	Enters LDP configuration mode.
Nodexon(config-mpls-router)# ldp router-id interface loopback 0 force	Configures the LDP router ID, which typically uses the IP address of a loopback interface.
Nodexon(config-mpls-router)# advertise-labels for bgp-routes [acl acl-name]	Distributes labels to BGP routes. ACL-based filtering is optional.
Nodexon(config-mpls-router)# show running-config	Displays existing configurations.

 By default, LDP only distributes labels to IGP routes but not to BGP routes. To distribute labels to BGP routes, run the **advertise-labels for bgp-routes** command.

In Method 1 of the Option C solution, you can run the **redistribute bgp subnets route-map routemap-name** command in IGP configuration mode to specify which BGP-learned routes are redistributed to IGP. You can run the **advertise-labels for bgp-routes acl acl-name** command in LDP configuration mode to specify which BGP routes are distributed with a label.

↘ Configuring a Multi-hop MP-EBGP Session

After an inter-AS LSP is established, establish a multi-hop MP-EBGP session between the two PEs in different ASs that need to carry the inter-AS VPN service, in order to allow the PEs to exchange VPN routes.

Configure the multi-hop MP-EBGP session in privileged mode according to the following table.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router bgp asn-num	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor ebgp-peer-address remote-as ebgp-asn-num	Establishes a multi-hop EBGp session with the PE in the other AS.
Nodexon(config-router)# neighbor ebgp-peer-address update-source interface-name	Specifies the loopback interface used to establish a neighbor relationship with the EBGp peer.
Nodexon(config-router)# neighbor ebgp-peer-address ebgp-multi-hop	Configures multi-hop attributes.
Nodexon(config-router)# address-family vpnv4	Enters BGP VPN address family configuration mode.
Nodexon(config-router-af)# neighbor ebgp-peer-address activate	Enables the capability of exchanging VPN routes between peers.
Nodexon(config-router-af)# exit	Exits BGP VPN address family configuration mode.
Nodexon(config-router)# address-family ipv4	Enters BGP IPv4 address family configuration mode.

Command	Description
Nodexon(config-router-af)# no neighbor ebgp-peer-address	Disables the capability of exchanging IPv4 routes.
activate(config-router)# show running-config	Displays existing configurations.

i Avoid the situation where the multi-hop MP-EBGP peers exchange IPv4 routes or the routes corresponding to the two addresses used for BGP session establishment. If such routes are exchanged over the multi-hop MP-EBGP session, one PE has two routes destined for the PE in the other AS. One route is advertised by the ASBR in the local AS, and the other is advertised over the multi-hop MP-EBGP session. Because EBGP routes take precedence over IBGP routes, BGP preferentially selects the route advertised over the multi-hop MP-EBGP session, causing constant flapping of the route destined for the peer PE. As a result, VPN routes become unreachable.

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

Inter-AS VPN Option C: Enabling IPv4 Label Switching Between EBGP Neighbors

<p>Scenario Figure 2-31</p>	<p>Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the

	<p>interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none"> ● On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. ● On ASBR1, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR2. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS. Configure an ACL to distribute labels only to specified BGP routes. (The ACL is optional and used to reduce the number of undesired route entries.) Configure a backbone routing protocol, which redistributes only BGP routes compliant with the route map. (The route map is optional and used to reduce the number of undesired route entries.) Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface. ● On ASBR2, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR1. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS. Configure an ACL to distribute labels only to specified BGP routes. (The ACL is optional and used to reduce the number of undesired route entries.) Configure a backbone routing protocol, which redistributes only BGP routes compliant with the route map. (The route map is optional and used to reduce the number of undesired route entries.) Configure the IP address of the interface connected to ASBR1, and enable label forwarding on the interface.

1.1.1.1 is unreachable.
```

Common Errors

The capability of exchanging IPv4 routes over multi-hop EBGP is not disabled when a multi-hop MP-EBGP session is configured. LDP is not configured on ASBRs for distributing labels to BGP routes, causing a communication failure between VPN sites.

2.4.4.2 Method 2: Enable IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors

As Method 1 enables IPv4 label switching only between EBGP neighbors, IGP and LDP in one AS need to maintain the routes destined for PEs in the other AS. That is, the inter-AS routes of PEs must be propagated to all devices between ASs. In actual application, for AS security consideration, the routes of PEs in one AS should not be propagated to each device in the other AS. Rather, the routes must be maintained only by BGP and transparent to IGP and LDP in the same AS. To meet this requirement, you can enable IPv4 label switching between EBGP neighbors and between IBGP neighbors.

Different from Method 1, Method 2 does not require IGP on ASBRs to redistribute BGP routes and does not require LDP to distribute labels to BGP routes. LDP is only responsible for LSP establishment in the local AS. However, IPv4 label switching must be enabled between IBGP neighbors and between EBGP neighbors for inter-AS LSP establishment, and PEs must support stacking of three consecutive labels.

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure PEs and ASBRs to establish an IBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure a multi-hop MP-EBGP session.

↘ Configuring PEs and CEs to Exchange Routes

For details, see "Configuring PEs and CEs to Exchange Routes" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring IGP and MPLS Signaling for ASs

For details, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring PEs and ASBRs to Establish an IBGP Session in Order to Distribute Labels to IPv4 Routes

In Method 1, the routes of PEs learned over EBGP are redistributed to IGP between ASs, whereas in Method 2, the inter-AS routes of PEs are transmitted over the IBGP session between ASBR and PE, and labels are distributed to those routes over BGP.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>peer-address</i> remote-as <i>asn-number</i>	Establishes an IBGP session with the ASBR (PE).
Nodexon(config-router)# neighbor <i>peer-address</i> update-source <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the BGP session established with the peer ASBR (PE)
Nodexon(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Nodexon(config-router-af)# neighbor <i>peer-address</i> send-label	Configures the capability of exchanging labeled IPv4 routes with the peer ASBR (PE).
Nodexon(config-router-af)# show running-config	Displays existing configurations.

- i** Before you enable IPv4 label switching over the IBGP session between IBGP peers, run the **neighbor update-source** command to specify the address of a loopback interface as the source address for the IBGP session; otherwise, an inter-AS LSP cannot be established.

↘ [Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes](#)

For details, see "Configuring ASBRs to Establish an EBGP Session in Order to Distribute Labels to IPv4 Routes" in section 2.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors."

↘ [Configuring a Multi-hop MP-EBGP Session](#)

For details, see "Configuring a Multi-hop MP-EBGP Session" in section 2.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBGP Neighbors."

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

↘ [Inter-AS VPN Option C: Enabling IPv4 Label Switching Between EBGP Neighbors and Between IBGP Neighbors](#)

Scenario
Figure 2-32

Requirements: A VPN has sites in two ASs. Enable inter-AS communication between the sites.

Configuration Steps

- On PE1-AS1, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Establish an IBGP session with ASBR1. Enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On PE1-AS2, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Configure a multi-hop MP-EBGP session. Disable the capability of exchanging IPv4 routes over EBGP. Establish an IBGP session with ASBR2. Enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.
- On P1-AS1, configure a loopback interface, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.
- On ASBR1, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR2. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the interface connected to ASBR2, and enable label forwarding on the interface.
- On ASBR2, configure a loopback interface, and configure an ACL and a route map to distribute or set labels only for compliant routes. Establish an EBGP session with ASBR1. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Configure statically the routes of PEs in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the

	interface connected to ASBR1, and enable label forwarding on the interface.

Common Errors

The capability of exchanging IPv4 routes over multi-hop EBGP is not disabled when a multi-hop MP-EBGP session is configured. IPv4 label switching is not configured between IBGP neighbors, causing a communication failure between VPN sites.

2.4.4.3 Method 3: Establish Multi-hop MP-EBGP Between RRs

The Option C solution requires inter-AS VPN sites to be fully meshed. A new VPN site must set up a multi-hop MP-EBGP connection with PEs in the other AS. This hampers VPN site scalability. To address this problem, you can deploy an RR in each AS and enable the RRs in different ASs to set up a multi-hop MP-EBGP connection for exchanging VPN routes.

Figure 2-33 Establishment of Inter-RR Multi-hop MP-EBGP for Option C

Configuration Steps

- (Mandatory) Configure PEs and CEs in each AS to exchange routes.
- (Mandatory) Configure IGP and MPLS signaling for ASs.
- (Mandatory) Configure RRs to establish an MP-IBGP session with PEs, and configure IPv4 label switching.

- (Mandatory) Configure RRs to establish an IBGP session with ASBRs, and configure IPv4 label switching.
- (Mandatory) Configure ASBRs to establish an EBGP session in order to distribute labels to IPv4 routes.
- (Mandatory) Configure a multi-hop MP-EBGP session.

For details, see "Configuring an MPLS Network" in section 2.4.1 "Configuring BGP MPLS IP VPN Basic Functions."

↘ Configuring RRs to Establish an MP-IBGP Session with PEs, and Configuring IPv4 Label Switching

Configure RRs to establish an MP-IBGP session with PEs for exchanging VPN routes, and enable IPv4 label switching over the MP-IBGP session.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>peer-address remote-as</i> <i>asn-number</i>	Establishes an IBGP session.
Nodexon(config-router)# neighbor <i>peer-address update-source</i> <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the IBGP session.
Nodexon(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Nodexon(config-router-af)# neighbor <i>peer-address activate</i>	Enables the capability of exchanging IPv4 routes.
Nodexon(config-router-af)# neighbor <i>peer-address send-label</i>	Enables IPv4 label switching.
Nodexon(config-router-af)# neighbor <i>peer-address route-reflector-client</i>	Configures peer PEs as the clients for reflecting IPv4 routes on the RRs.
Nodexon(config-router-af)# exit	Exits IPv4 address family configuration mode.
Nodexon(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Nodexon(config-router-af)# neighbor <i>peer-address activate</i>	Enables the capability of exchanging VPN routes between peers.
Nodexon(config-router-af)# neighbor <i>peer-adderss route-reflector-client</i>	Configures peer PEs as the clients for reflecting VPN routes on the RRs.
Nodexon(config-router-af)# show running-config	Displays existing configurations.

↘ Configuring RRs to Establish an IBGP Session with ASBRs, and Configuring IPv4 Label Switching

Configure ASBRs to establish an MP-IBGP session with RRs, so that ASBRs receive from RRs the routes destined for PEs in the local AS, and send RRs the routes destined for PEs in the other AS. You also need to enable IPv4 label switching over the MP-IBGP session.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>peer-address remote-as</i> <i>asn-number</i>	Establishes an IBGP session.
Nodexon(config-router)# neighbor <i>peer-address update-source</i> <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the IBGP session.
Nodexon(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Nodexon(config-router-af)# neighbor <i>peer-address activate</i>	Enables the capability of exchanging IPv4 routes.
Nodexon(config-router-af)# neighbor <i>peer-address send-label</i>	Enables IPv4 label switching.
Nodexon(config-router)# show running-config	Displays existing configurations.

-  When you configure RRs to establish an IBGP session with ASBRs, you do not need to configure the ASBRs as the clients of the RRs, unless the ASBRs also function as PEs.

↘ [Configuring ASBRs to Establish an EBG Session in Order to Distribute Labels to IPv4 Routes](#)

For details, see "Configuring ASBRs to Establish an EBG Session in Order to Distribute Labels to IPv4 Routes" in section 2.4.4.1 "Method 1: Enable IPv4 Label Switching Only Between EBG Neighbors."

↘ [Configuring a Multi-hop MP-EBGP Session](#)

Establish a multi-hop MP-EBGP session between the RRs in two different ASs for exchanging inter-AS VPN routes. You also need to disable the capability of exchanging IPv4 routes over the MP-EBGP session. Routes arriving at one PE are transmitted by the corresponding ASBR to the other AS.

Perform configuration in privileged mode according to the following table.

Command	Description
Nodexon# config terminal	Enters global configuration mode.
Nodexon(config)# router bgp <i>asn-number</i>	Configures BGP and enters BGP configuration mode.
Nodexon(config-router)# neighbor <i>rr-address remote-as</i> <i>ebgp-asn-numbe</i>	Establishes an EBG session.
Nodexon(config-router)# neighbor <i>rr-address update-source</i> <i>interface-name</i>	Specifies the address of a loopback interface as the source address for the EBG session.
Nodexon(config-router)# neighbor <i>rr-address ebgp-multi-hop</i>	Configures multi-hop EBG attributes.
Nodexon(config-router)# address-family ipv4	Enters IPv4 address family configuration mode.
Nodexon(config-router-af)# no neighbor <i>rr-address activate</i>	Disables the capability of exchanging IPv4 routes over the MP-EBGP session.

Nodexon(config-router-af)# exit	Exits IPv4 address family configuration mode.
Nodexon(config-router)# address-family vpnv4	Enters VPN address family configuration mode.
Nodexon(config-router-af)# neighbor rr-address activate	Enables the capability of exchanging VPN routes with the RR in the other AS.
Nodexon(config-router-af)# neighbor rr-address next-hop-unchanged	(Optional) Configures next hop retention for VPN routes advertised to the peer.
Nodexon(config-router)# show running-config	Displays existing configurations.

- i** By default, the next hop in VPN routes advertised to the EBGP peer is changed to the sender. Then the PEs in the other AS determine that the next hop in incoming VPN routes is an RR, causing all inter-AS VPN traffic to pass through the RR. Such a forwarding path is not the best path, and RRs require higher performance to forward traffic. To avoid the preceding situation, run the **neighbor next-hop-unchanged** command in VPNv4 address family configuration mode to configure next hop retention for VPNv4 routes sent to the BGP peer when you configure a multi-hop MP-EBGP connection on RRs.
- i** Avoid the situation where the multi-hop MP-EBGP peers exchange IPv4 routes or the routes corresponding to the two addresses used for BGP session establishment. If such routes are exchanged over the multi-hop MP-EBGP session, one PE has two routes destined for the PE in the other AS. One route is advertised by the ASBR in the local AS, and the other is advertised over the multi-hop MP-EBGP session. Because EBGP routes take precedence over IBGP routes, BGP preferentially selects the route advertised over the multi-hop MP-EBGP session, causing constant flapping of the route destined for the peer PE. As a result, VPN routes become unreachable.

Verification

- Check that sites of the same VPN can communicate with each other but sites of different VPNs cannot communicate with each other.

Configuration Example

Inter-AS VPN Option C: RR Networking

Scenario

Figure 2-34

The diagram illustrates three Autonomous Systems (AS1, AS2, AS3) interconnected. Each AS contains a PE, RR, and ASBR. VPN1 sites are distributed across all three ASes. Connections are shown between PE-RR, RR-ASBR, and across AS boundaries. IP addresses and interface identifiers are provided for each component.

AS	Component	Loopback (Lo)	Interfaces	Subnet
AS1	PE1-AS1	1.1.1.1	Gi1/0:1	20.20.20.0/24
	RR-AS1	2.2.2.2	Gi1/1:2	10.10.10.0/24
	ASBR1	3.3.3.3	Gi1/1:2	30.30.30.0/24
AS2	PE1-AS2	5.5.5.5	Gi1/1:2	50.50.50.0/24
	RR-AS2	6.6.6.6	Gi1/0:1	40.40.40.0/24
	ASBR2	4.4.4.4	Gi1/2:1	60.60.60.0/24
AS3	PE1-AS3	9.9.9.9	Gi1/1:2	80.80.80.0/24
	RR-AS3	8.8.8.8	Gi1/0:1	70.70.70.0/24
	ASBR3	7.7.7.7	Gi1/1:2	70.70.70.0/24

When you apply the Option C solution, to ensure reachability between sites of the same VPN located in different ASs (in Figure 2-, sites of VPN1 are located in three different ASs), you need to configure PEs to be fully meshed across the ASs over BGP. A new VPN site needs to set up a BGP connection with existing

	<p>VPN sites. This limits the Option C application. To ensure scalability, you can add an RR to each AS and set up a multi-hop MP-EBGP connection between RRs in different ASs to exchange inter-AS VPN routes. Then establish an MP-IBGP session between the PE and the RR in each AS.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On PE1-AS1, PE1-AS2, and PE1-AS3, configure a loopback interface, create a VRF table named VPN1, define RD and RT values, and associate the VRF table with the corresponding interface. Establish an MP-IBGP session with the RR in the same AS, and enable IPv4 label switching. Configure a CE neighbor relationship over EBGP. ● On RR-AS1, RR-AS2, and RR-AS3, configure a loopback interface, establish an MP-IBGP session with the PE in the same AS, specify the PE as the RR client, and enable IPv4 label switching. Establish a multi-hop MP-EBGP session with the peer RR, and configure next hop retention for VPN routes exchanged with the peer RR. Disable the capability of exchanging IPv4 routes with the peer RR. Establish an IBGP session with the ASBR in the same AS. Enable IPv4 label switching. Configure MPLS, and configure OSPF for the backbone network to transmit routes. ● On ASBR1, ASBR2, and ASBR3, configure a loopback interface, and configure an ACL and a route map. Establish an EBGP session with the peer ASBR. Enable IPv4 label switching. Configure a route map to set labels only for the compliant routes of PEs. (The route map is optional and used to specify which routes are distributed with a label over BGP.) Establish an IBGP session with the RR in the same AS. Enable IPv4 label switching. Configure a route map to set labels only for the compliant inter-AS routes of PEs. Configure statically the route of the PE in the local AS. Configure MPLS signaling and enable MPLS on the interface connected to the public network. Configure OSPF for the backbone network to transmit routes. Configure the IP address of the interface connected to the peer ASBR, and enable label forwarding on the interface.

Common Errors

- The capability of exchanging IPv4 routes is not disabled when a multi-hop MP-EBGP session is configured between RRs, or next hop retention is not configured for VPN routes exchanged over the multi-hop MP-EBGP session, causing a communication failure between VPN sites.

2.4.5 Configuring OSPF VPN Extended Attributes

Configuration Effect

When VPN user networks run OSPF, implement OSPF between PE and CE to simplify CE configuration and management.

Notes

- The LDP router ID must consist of 32 bits.

Configuration Steps

- (Optional) Configure a domain ID.
- (Optional) Configure a VPN route tag.
- (Optional) Configure a sham link.
- (Optional) Configure capability vrf-lite.
- (Optional) Configure extcommunity-type.

▾ (Optional) Configuring a Domain ID

A domain ID indicates the domain to which an OSPF instance belongs. Typically, all VRF OSPF instances of the same VPN are configured with the same domain ID. The default domain ID of an OSPF instance is Null, and the default type is 0x0005.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# domain-id { <i>ip-address</i> [<i>secondary</i>] null type { 0005 0105 0205 8005 } value <i>hex-value</i> [secondary] }	Configures the domain ID of the OSPF instance.
Nodexon(config-router)# show running-config	Displays existing configurations.

- ❗ The **domain-id** command takes effect only for VRF OSPF instances.
- ❗ A VRF OSPF instance can be configured with multiple domain IDs, but only one domain ID is the primary domain ID, and the other domain IDs are secondary domain IDs. The primary domain ID is configured using the **domain-id value** command, and the secondary domain IDs are configured using the **domain-id value secondary** command. The VPN route converted from an OSPF route contains only the primary domain ID.
- ❗ The primary and secondary domain IDs can be configured using the **domain-id ip-address** command or the **domain-id type { 0005 | 0105 | 0205 | 8005 } value** command.

- i** You can configure the domain IDs of different VRF OSPF instances to be the same. The VRF OSPF instances of the same VPN must be configured with the same domain ID to ensure correct route advertisement.

▾ (Optional) Configuring a VPN Route Tag

By default, the VPN route of an OSPF instance is marked by the AS number of local BGP.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# domain-tag <i>value</i>	Configures a VPN route tag for the OSPF instance. The value range is <1–4294967295>.
Nodexon(config-router)# show running-config	Displays existing configurations.

- i** The **domain-tag** *value* command takes effect only for VRF OSPF instances.
- i** If VRF-specific **domain-tag** is not configured manually, the default value is the AS number of local BGP.

In L3VPN, if a VPN site is connected to multiple PEs, the VPN route that a PE learns over MP-BGP is advertised to the VPN site over a type 5 or 7 LSA. If another PE connected to the VPN site learns and advertises the VPN route, a loop occurs. To avoid the loop, configure the same VPN route tag for the VRF OSPF instances of the PEs connected to the same VPN site. The type 5 or 7 LSA that a VRF OSPF instance sends to the VPN site carries a VPN route tag. When another PE receives the type 5 or 7 LSA, it checks whether the VPN route tag in the LSA is the same as that of the corresponding OSPF instance. If they are the same, the LSA is excluded from OSPF route calculation.

- i** Typically, OSPF instances of the same VPN are configured with the same VPN route tag.

▾ (Optional) Configuring a Sham Link

A sham link is applicable in the scenario where VPN sites are connected by a backdoor link. If you require that VPN data be still transmitted over the MPLS backbone network, create a sham link between the VRF OSPF instances on two PEs. In this way, the VRF OSPF instances establish an OSPF neighbor relationship over the sham link to distribute LSA packets.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# area <i>area-id</i> sham-link <i>source-address destination-address</i> [cost <i>number</i>] [dead-interval <i>seconds</i>][hello-interval <i>seconds</i>] [retransmit-interval <i>seconds</i>][transmit-delay <i>seconds</i>] [authentication [message-digest [null]]] [[authentication-key [0/7] <i>key</i>] [message-digest-key <i>key-id</i> [0/7] <i>key</i>]]	Configures the area ID, source address, and destination address of the sham link.
Nodexon(config-router)# show running-config	Displays existing configurations.

A sham link must be configured on two PEs. A single PE does not support sham link creation.

The two PEs for sham link creation must meet the following configuration requirements:

- The PEs must be configured with the same area ID of the sham link.
 - The PEs must be configured with the same <source address, destination address> combination of the sham link.
 - The source address and destination address of the sham link must be the 32-bit loopback interface addresses bound to the VRF tables on PEs.
-
- ❗ OSPF routes advertised over a sham link are not used for forwarding because the routes do not have a VPN route tag. Forwarding is still implemented by BGP VPNv4 routes. Therefore, ensure that routes learned over the sham link can also be learned over MP-BGP.
 - ❗ The source address used for sham link creation must be used by VPNv4 route advertisement over BGP, but the source address cannot be used by VRF OSPF instances for route calculation.
-

📌 (Optional) Configuring capability vrf-lite

By default, VRF OSPF instances support the PE-CE OSPF feature (LSA conversion based on the domain ID, DN bit, and VPN route tag). You can run the **capability vrf-lite** command to disable the PE-CE OSPF feature for VRF OSPF instances.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# capability vrf-lite [auto]	Disables the PE-CE OSPF feature for VRF OSPF instances.
Nodexon(config-router)# show running-config	Displays existing configurations.

- ❗ The **capability vrf-lite** command takes effect only for VRF OSPF instances.
 - ❗ The loop detection function can be disabled for VRF OSPF instances in some application scenarios. For example, if VPN routes are exchanged between MCE and PE over OSPF, you need to run the **capability vrf-lite** command to disable the loop detection function for the VRF OSPF instance on the MCE to allow for route learning between VPN sites.
-

📌 (Optional) Configuring extcommunity-type

After an OSPF route is redistributed to BGP to form a VPN route, the VPN route carries the extended community attributes of the OSPF route, including the router-id and route-type extended community attributes. By default, the router-id extended community attribute belongs to the 0x0107 type, and the route-type extended community attribute belongs to the 0x0306 type. You can use a command to manually configure the types of the router-id and route-type extended community attributes.

Command	Description
Nodexon# configure terminal	Enters global configuration mode.
Nodexon(config)# router ospf <i>ospf-id</i> vrf <i>vrf-name</i>	Creates an OSPF instance and enters OSPF configuration mode.
Nodexon(config-router)# extcommunity-type { router-id { 0107 8001 } route-type { 0306 8000 } }	Configures the OSPF router-id and route-type extended community attributes.
Nodexon(config-router)# show running-config	Displays existing configurations.

- i** The **extcommunity-type** command takes effect only for VRF OSPF instances.
- i** The router-id type configuration is intended for compatibility with different vendors. For example, when you interwork with a vendor that only supports the 0x0107 type, you need to run the **extcommunity-type** command to change the type of router-id to 0x0107.
- i** The router-type type configuration is intended for compatibility with different vendors. For example, when you interwork with a vendor that only supports the 0x8000 type, you need to run the **extcommunity-type** command to change the type of router-type to 0x8000.

Verification

- Check that VPN sites can communicate with each other.

Configuration Example

Configuring a Domain ID

<p>Scenario Figure 2-39</p>	 <p>Two sites of a customer exchange VPN routes over the MPLS backbone network. The sites access PEs over OSPF. The OSPF routes that are exchanged over the MPLS backbone network must be restored to the maximum extent to OSPF routes supported by the sites.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On SiteA and SiteB, configure OSPF used for exchanging routes between PE and CE. ● On PE1 and PE2, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure BGP, and establish an MP-IBGP session with PE2. Configure the capability of exchanging routes with the CE over OSPF. Set the domain ID of the OSPF instance to 10. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On P1 and P2, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.
<p>VPNA-SiteA</p>	<pre> VPNA-SITEA# configure terminal VPNA-SITEA(config)# router ospf 10 </pre>

Configuring a Sham Link

Scenario
 Figure 2-40

Two sites of a customer exchange VPN routes over the MPLS backbone network. A backdoor link is established between the sites to exchange VPN routes when the MPLS backbone network fails.

Configuration Steps

- On SiteA, configure OSPF for communicating with PE1 and configure OSPF over the backdoor link for communicating with SiteB. Set the OSPF cost in interface configuration mode.
- On SiteB, configure OSPF for communicating with PE2 and configure OSPF over the backdoor link for communicating with SiteA. Set the OSPF cost in interface configuration mode.
- On PE1, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure a loopback interface for the VRF table for establishing a sham link. Configure BGP, and establish an MP-IBGP session with PE2. Configure the capability of exchanging

	<p>routes with the CE over OSPF. Establish a sham link with the OSPF instance on PE2. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol.</p> <ul style="list-style-type: none"> ● On PE2, configure a loopback interface, create a VRF table named VPNA, define RD and RT values, and associate the VRF table with the corresponding interface. Associate the CE-connected interface with the VRF table. Configure a loopback interface for the VRF table for establishing a sham link. Configure BGP, and establish an MP-IBGP session with PE1. Configure the capability of exchanging routes with the CE over OSPF. Establish a sham link with PE1. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. ● On P1, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol.

➤ **Configuring Multiple OSPF Instances per MCE**

<p>Scenario Figure 2-50</p>	<p>The sites of a customer operate different services. The customer requires that routes of the same service be exchanged over the MPLS backbone network and different services be isolated from each other.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On MCE-A and MCE-B, configure a trunk link between PE and CE, configure two VRF tables for different services, and bind an interface to each VRF table. Configure the two VRF tables to communicate with the PE over OSPF. On PE1 and PE2, configure a loopback interface, configure a trunk link between PE and CE, create two VRF tables named VPN1 and VPN2 for different services, and associate the VRF tables with corresponding interfaces. Associate the CE-connected interface with a VRF table. Configure BGP, and establish an MP-IBGP session with the peer PE (PE2 or PE1). Configure the capability of exchanging routes with the CE over OSPF. Configure backbone MPLS signaling. Enable MPLS on the interface connected to the public network. Configure a backbone routing protocol. On P1, configure backbone MPLS signaling, enable MPLS on the interface connected to the public network, and configure a backbone routing protocol. <p>i This example uses the configuration of the SVI and the 802.1Q sub-interface to describe how to connect PE1 and MCE-A. Some devices may not support the two interfaces. PE1 and MCE-A can be connected by any two links (physical or logical) based on two routing adjacencies between them. You can select a suitable connection method according to the actual condition.</p>
<p>MCE-A</p>	<pre>MCE-A# configure terminal MCE-A(config)# interface GigabitEthernet 1/0 MCE-A(config-if-GigabitEthernet 1/0)# switchport mode trunk MCE-A(config-if-GigabitEthernet 1/0)# end MCE-A# configure terminal MCE-A(config)# ip vrf VPN1</pre>

Common Errors

An LDP session fails to be established because the router ID does not consist of 32 bits.

2.5 Monitoring

Clearing

Description	Command
Resets the VPNv4 unicast address family of BGP.	clear bgp vpnv4 unicast { * <i>as-number</i> <i>peer-address</i> } [soft] [in out]
Clears VPNv4 route flapping information and cancels VPNv4 route suppression.	clear bgp vpnv4 unicast dampening [<i>ip-address</i> [<i>mask</i>]]
Resets all EBGp connections under the VPNv4 address family.	clear bgp vpnv4 unicast external [soft] [in out]
Clears route flapping statistics under the VPNv4 address family.	clear bgp vpnv4 unicast flap-statistics [<i>ip-address</i> [<i>mask</i>]]
Resets the VPNv4 address family for all members of the BGP peer group.	clear bgp vpnv4 unicast peer-group <i>peer-group-name</i> [soft] [in out]
Resets the BGP session under a VRF table.	clear ip bgp vrf <i>vrf-name</i> { * <i>address</i> <i>as-num</i> } [soft] [in out]

Displaying

Description	Command
Displays the IPv4 routes with an MPLS label that are learned and sent over BGP.	show bgp ipv4 unicast labels
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP.	show bgp vpnv4 unicast all [<i>network</i> neighbor [<i>peer-address</i>]] [summary label]
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP under the specified VRF table.	show bgp vpnv4 unicast vrf <i>vrf_name</i> [<i>network</i> summary label]
Displays the VPNv4 routes or the neighbor information that are learned and sent over BGP under the specified RD.	show bgp vpnv4 unicast rd <i>rd_value</i> [<i>network</i> summary label]
Displays the configurations of an extcommunity list.	show ip extcommunity-list [<i>extcommunity-list-num</i> <i>extcommunity-list-name</i>]
Displays the OSPF sham link information.	show ip ospf [<i>process-id</i>] sham-links [area <i>area-id</i>]
Displays the configured single-protocol VRF information.	show ip vrf [brief detail interfaces] [<i>vrf-name</i>]
Displays brief information about VRF tables (single- and multi-protocol VRF tables).	show vrf brief [<i>vrf-name</i>]

Description	Command
Displays brief information about the IPv4 address family for VRF tables (single- and multi-protocol VRF tables).	show vrf ipv4 [<i>vrf-name</i>]
Displays brief information about the IPv6 address family for multi-protocol VRF tables.	show vrf ipv6 [<i>vrf-name</i>]
Displays detailed information about VRF tables (single- and multi-protocol VRF tables).	show vrf detail [<i>vrf-name</i>]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables BGP MPLS debugging.	debug ip bgp mpls
Enables MPLS entry debugging.	debug mpls
Enables MPLS message debugging.	debug mpls msg [<i>send</i> <i>rcv</i>]

3 Configuring MPLS GR

i The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols. We use "router series" or "switch series" to refer to specific devices.

3.1 Overview

The Internet Engineering Task Force (IETF) extends the Multiprotocol Label Switching (MPLS) signaling protocol – Label Distribution Protocol (LDP). In this way, when LDP is restarted, a device can notify its neighbor to retain MPLS forwarding entries for a period and mark these entries as "Old". Peripheral devices assist the device in information synchronization so that the device can return to the condition before the LDP restart within a short time. If the packet forwarding path is not changed during the LDP restart, the system can forward data continuously, thereby providing reliable MPLS services.

Virtual Private Wire Service (VPWS) and Virtual Private LAN Service (VPLS) use basic MPLS networks to establish public tunnels and use extended LDP to distribute virtual circuit (VC) labels and establish VCs. Therefore, for continuous VPWS and VPLS forwarding, extended LDP Graceful Restart (GR) must be implemented. Despite different MPLS forwarding entries, extended LDP GR and basic LDP GR are implemented in the same way. Therefore, extended LDP GR and basic LDP GR can be processed uniformly.

Layer-3 Virtual Private Network (L3VPN) GR enables continuous L3VPN forwarding. When the control plane of a device fails, VPN forwarding continues, which protects VPNs.

Protocols and Standards

- RFC3036: LDP Specification
- RFC3037: LDP Applicability
- RFC3215: LDP State Machine
- RFC3478: Graceful Restart Mechanism for Label Distribution Protocol
- RFC3479: Fault Tolerance for the Label Distribution Protocol (LDP)
- RFC 4724: Graceful Restart Mechanism for BGP

3.2 Applications

Application	Description
L3VPN GR	Deploying GR on a device that enables MPLS L3VPN (for example, a PE device) ensures that users can forward their services in case of any fault, thereby improving reliability.

3.2.1 L3VPN GR

Figure 3-1

Remarks	<p>CE devices represent a customer network and run the IGP or External Border Gateway Protocol (EBGP).</p> <p>PE and P devices form a provider network and run the IGP.</p> <p>PE1, P and PE2 establish public network tunnels through LDP and establish LSPs.</p> <p>PE1 and PE2 establish private network tunnels through extended Internal Border Gateway Protocol (IBGP).</p> <p>IGP, BGP and LDP have the GR capability.</p> <p>PE devices are GR-Capable routers, and the P device is a GR-Aware router.</p>
---------	--

The following describes the GR process on PE1. The active and standby supervisor modules are switched over on PE1. PE1 serves as a GR Restarter, while P and PE2 serve as GR Helpers. Active and standby supervisor modules are switched over in three phases:

▾ Before the Active/Standby Supervisor Module Switchover

PE1 negotiates with CE1 about IGP or External BGP (EBGP) GR, negotiates with P about IGP and LDP GR, and negotiates with PE2 about Internal BGP (IBGP) GR.

PE1 sends P an initialization message with FT session TLV options to establish a GR-capable LDP session. Then the devices exchange addresses and label mapping messages. In this way, GR-capable LSPs are established for data forwarding.

PE1 sends PE2 a GR-capable <AFI=IPv4, SAFI=Unicast> and <AFI=IPv4, SAFI=VPNv4> Open message to establish a GR-capable IBGP session.

When the active supervisor module works normally, you need to back up the GR data to the standby supervisor module so that after active and standby supervisor modules are switched over, PE1 can read the data during the GR protocol restart and use it for GR.

▾ During the Active/Standby Supervisor Module Switchover

After the GR data is backed up to the standby supervisor module, PE1 switches over active and standby supervisor modules.

P detects TCP sessions in Down state and marks the corresponding LSPs as "Old". The device enables the forwarding entry aging timer. Packet forwarding will be continued before a timeout.

When detecting disconnected TCP, PE2 immediately mark the routes learned from PE1 as "Old" and enables a restart timer for PE1. If PE2 does not receive the Open message before a timeout, it will delete the "Old" flag; if PE2 receives the Open message, it will delete the restart timer. PE1 and PE2 continue traffic forwarding through original routes.

▾ After the Active/Standby Supervisor Module Switchover

On PE1, the standby supervisor module becomes an active supervisor module and the active supervisor module becomes a standby supervisor module. PE1 checks the GR data backed up to the new active supervisor module for forwarding entries before the protocol restart. Then devices initialize their CLIs and enable GR. During IGP, BGP, and LDP GR, the devices notify all IGP and LDP neighbors to re-establish connections.

- IGP convergence

PE1 sends P a GR-capable initialization message, and re-establishes the session upon receipt of a response to obtain topology and routing information. Then PE1 re-calculates the routing table and deletes "Old" routes. In this way, IGP converges.

- BGP processing

PE1 and CE1 exchange routing information. Then PE1 updates the routing table and forwarding entries based on route forwarding information and replaces invalid routing information. In this way, BGP converges.

PE1 and PE2 establish a new BGP session in between. First, PE1 sends PE2 an Open message with GR options. Then PE1 receives an Update message from PE2 and processes the message. The Update message includes IP address prefixes. PE1 selects BGP routes when receiving an End-of-RIB (EOR) flag. PE1 sends PE2 the Update message with IP address prefixes and then sends PE2 the EOR flag. PE2 selects routes upon receipt of the EOR flag. In this way, the network converges.

- LDP processing

PE1 sends P a GR-capable initialization message. A GR-capable LDP session is established when P receives the message. The devices re-exchange addresses and label mapping messages and delete or retain the "Old" flag for MPLS forwarding entries. After GR, the devices delete "Old" MPLS forwarding entries.

i IGP GR, BGP GR, and LDP GR are processed in no particular order. Unicast routes converge first and then are advertised to LDP.

! Before all protocols finish GR, PE1 only updates the RIB of the active supervisor module.

! After all protocols finish GR, PE1 updates the FIB of the interface module.

Deployment

i The prerequisite for implementing L3VPN GR is that the continuous forwarding of routing protocols must be supported and the hardware must support 1 + 1 redundant backup for management modules.

i continuous forwarding of routing protocols means that a unicast routing protocol must support GR; that is, the device must support Open Shortest Path First (OSPF) GR, Intermediate System to Intermediate System (IS-IS) GR, or BGP GR.

- PE1, P and PE2 create an L3VPN environment where L3VPN is configured to provide L3VPN services for users.
- IGP GR is configured for CE1, PE1, P, PE2 and CE2 to continuously forward routing protocols.
- BGP GR is configured for PE1 and PE2 to continuously forward private routes.
- LDP GR is configured for PE1, P and PE2 to continuously forward public MPLS.

3.3 Features

Basic Concepts

GR Capability-related Router

In terms of the GR capability, GR-Capable routers, GR-Aware routers, and GR-Unaware routers are available.

- GR-Capable router

A GR-Capable router has the GR capability. It is usually equipped with dual supervisor modules, which enables 1+1 redundancy. During the active/standby supervisor module switchover, the router notifies neighbors to retain its forwarding entries. After the switchover, the router re-establishes the routing table without route flapping, and the packet forwarding path is not changed. In this way, continuous forwarding is enabled.

- GR-Aware router

A GR-Aware router is aware of GR. It may not have dual supervisor modules, but it is aware of GR on neighbors and can help neighbors finish GR.

- GR-Unaware router

A GR-Unaware router is unaware of GR on neighbors and cannot help neighbors finish GR because software does not have a GR feature or the GR feature is disabled.

↳ **GR Role-related Router**

During the router restart, in terms of the role, GR Restarters and GR Helpers are available.

- GR Restarter

A GR Restarter restarts because of the administrator operation or failures. It must be a GR-Capable router.

- GR Helper

A GR Helper is the neighbor of a GR Restarter. It is at least a GR-Aware router.

Overview

Feature	Description
LDP GR	When the MPLS device is faulty, the function maintains the neighbor relationship and sessions between routers, and recovers the session connection and label information subsequently to prevent common MPLS and L2VPN forwarding from being interrupted.

3.3.1 LDP GR

By using LDP GR together with IGP GR, you can achieve uninterrupted common MPLS or L2VPN forwarding. If further using BGP GR, you can achieve uninterrupted L3VPN forwarding.

To establish a GR-capable LDP session, both ends must support and enable LDP GR. If one end does not support GR, only ordinary LDP sessions can be established. If the active side supports and enables LDP GR, it will add FT Session TLV to an initialization message.

If the passive side receives an initialization message with FT Session TLV, it can decide whether to add FT Session TLV to an initialization message. If it supports and enables LDP GR, it will add FT Session TLV to an initialization message and thereby a GR-capable LDP session is established; otherwise, it will not add FT Session TLV to an initialization message and thereby an ordinary LDP session is established. If the passive side receives an initialization message without FT Session TLV, an ordinary LDP session will be established whether the passive side adds FT Session TLV to an initialization message. The following figure shows the process of LDP session establishment between two GR-capable LSRs.

Working Principle

Figure 3-2

Related Configuration

Enabling LDP GR

By default, LDP GR is enabled on devices enabling LDP.

In LDP mode, by running the **graceful-restart** command, you can enable or disable LDP GR.

The GR capability of LDP can take effect only when LDP sessions are restarted.

Configuring LDP GR

By default, the Time To Live (TTL) of an LDP neighbor is 120 seconds; the time for re-connecting LDP sessions is 300 seconds; the LDP recovery time is 120 seconds.

- Run the **graceful-restart timer neighbor-liveness** command to configure the TTL of an LDP neighbor. During this period of time, the Helper waits for the Restarter to restart and then they re-establish the session. If it takes a long time for the Restarter to restart, you can extend the TTL.

- Run the **graceful-restart timer reconnect** command to configure the LDP session reconnection time. During this period of time, the Restarter holds the MPLS forwarding entries (corresponding to the MPLS forwarding state holding timer shown in the figure). If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.
- Run the **graceful-restart timer recovery** command to configure the LDP session recovery time. During this period of time, the Helper assists the Restarter in recovering MPLS forwarding entries after the session is re-established. If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.

3.4 Configuration

Configuration	Description and Command
LDP GR	 (Mandatory) It is used to configure LDP GR.
	graceful-restart Enables the GR capability of LDP.
	 (Optional) It is used to configure the LDP GR timer.
	graceful-restart timer reconnect Configures the time for re-connecting LDP sessions.
	graceful-restart timer neighbor-liveness Configures the TTL of an LDP neighbor.
	graceful-restart timer recovery Configures the time for recovering LDP sessions.

3.4.1 LDP GR

Configuration Effect

After MPLS LDP GR is configured, when MPLS devices fail, the neighbor relationship and sessions between routers can be maintained, and session connection and labels can be recovered.

Notes

-  The routing interface for configuring IP addresses must be a Layer-3 routing interface, or configuration will fail.
-  Topological changes during GR (for example, changes in the IP address or link of the Link-State Request (LSR) ID used before GR is deleted) may disable GR and interrupt service traffic.

You need to finish the following tasks before configuring MPLS LDP GR:

- Configuring IGP GR
- Configuring MPLS LDP sessions

Before configuring MPLS LDP GR, you need to configure the following:

- The LDP session reconnection time
- The TTL of an LDP neighbor

- The LDP session recovery time

Configuration Steps

↳ Enabling LDP GR

- Mandatory.
- Run the **no graceful-restart** command to disable the GR capability of LDP.
- Enable GR by default to support process restart. Except otherwise required, do not disable LDP GR.

i Enabling LDP GR will not affect LDP sessions; that is, LDP sessions will not be restarted. LDP GR takes effect only when LDP sessions are restarted.

↳ Configuring LDP GR

- Optional.
- Run the **graceful-restart timer neighbor-liveness** command to configure the TTL of an LDP neighbor. During this period of time, the Helper waits for the Restarter to restart and then they re-establish the session. If it takes a long time for the Restarter to restart, you can extend the TTL.
- Run the **graceful-restart timer reconnect** command to configure the LDP session reconnection time. During this period of time, the Restarter holds the MPLS forwarding entries (corresponding to the MPLS forwarding state holding timer shown in the figure). If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.
- Run the **graceful-restart timer recovery** command to configure the LDP session recovery time. During this period of time, the Helper assists the Restarter in recovering MPLS forwarding entries after the session is re-established. If it takes a long time to recover a large number of MPLS forwarding entries, you can extend the time.

Verification

- After GR is configured, the sessions previously established will not be affected, and the function will take effect only when new sessions are established.
- You can run the **show mpls ldp graceful-restart** command to display GR-capable sessions.
- You can run the **show mpls ldp neighbors** command to check whether a session has the GR capability.

Related Commands

↳ Enabling LDP GR

Command	graceful-restart
Parameter	N/A
Description	
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	The following describes how to use this command:

	<p>If LDP GR is enabled on a dual-engine device, when the active supervisor module fails (or active and standby supervisor modules are switched over manually), traffic forwarding will not be interrupted, and the MPLS forwarding state will not be changed after the LDP restart.</p> <p>By default, GR is enabled whether a device serves as a GR Restarter or a GR Helper.</p> <p>The changed configuration of LDP GR takes effect only when LDP sessions are restarted.</p>
--	---

↘ Configuring the LDP Session Reconnection Time

Command	graceful-restart timer reconnect <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the LDP session reconnection time, which ranges from 30 to 3,600 seconds.
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<ul style="list-style-type: none"> ● During GR, both GR Restarter and GR Helper use the LDP session reconnection time. ● A GR Restarter uses the LDP session reconnection time to retain "Old" entries. ● A GR Helper enables the liveness timer based on its neighbor-liveness time or received reconnection time, whichever is shorter, and retains the "Old" entries before a timeout. ● If it takes a long time to reconnect to a neighbor because of a large number of services, you need to adjust the reconnection time and neighbor-liveness time. In a typical L3VPN scenario, the time increases by 1 minute every 100 VPNs. ● The LDP session reconnection time takes effect only when LDP sessions are restarted.

↘ Configuring the TTL of an LDP Neighbor

Command	graceful-restart timer neighbor-liveness <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the TTL of an LDP neighbor, which ranges from 5 to 3,600 seconds.
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<ul style="list-style-type: none"> ● Only a GR Helper uses the TTL. ● A GR Helper enables the liveness timer based on its neighbor-liveness time or received reconnection time, whichever is shorter, and retains the "Old" entries before a timeout. ● The TTL of an LDP neighbor takes effect only when LDP sessions are restarted.

↘ Configuring the LDP Session Recovery Time

Command	graceful-restart timer recovery <i>seconds</i>
Parameter Description	<i>seconds</i> : Configures the LDP session recovery time, which ranges from 15 to 600 seconds.
Command Mode	This configuration is performed in config-mpls-router configuration mode.
Usage Guide	<ul style="list-style-type: none"> ● Only a GR Helper uses the LDP session recovery time. ● A GR Helper enables the recovery timer based on its recovery time or received recovery time, whichever is shorter, and retains the "Old" entries before a timeout.

- The LDP session recovery time takes effect only when LDP sessions are restarted.

▾ **Displaying Configuration Effect**

Command	show mpls ldp graceful-restart [all vrf vrf-name]
Parameter Description	all: Displays all VPN routing and forwarding (VRF, including global VRF) LDP GR sessions and session parameters. vrf vrf-name: Displays specified VRF LDP GR sessions and session parameters.
Command Mode	This configuration is performed in privileged user mode.
Usage Guide	Displays LDP GR sessions and session parameters.

Common Errors

- The basic MPLS or L3VPN environment is incomplete, which results in forwarding failure.
- The Restarter is configured with GR, while the neighboring Helper is not.
- IGP GR or BGP GR is not configured.
- There are many routes but the timer time is not long enough, which disables GR before all entries are recovered.
- Topology or configuration changes during GR, which interrupts service traffic.

3.4.1.1 LDP GR Configuration Example

<p>Scenario</p> <p>Figure 3-3</p>	 <ul style="list-style-type: none"> ● PEs and P form an MPLS network. ● PEs and P support LDP and have the GR capability. ● This section describes LDP GR configuration on PE1 and P. PE1 is a GR-Capable router and serves as a GR Restarter. P is a GR-Aware router and serves as a GR Helper.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the interface IP address, configure OSPF, and enable OSPF GR. ● Enable global MPLS forwarding, and enable MPLS labeled packet forwarding and LDP on an interface. ● Configure LDP to enable MPLS traffic forwarding. ● Enable LDP GR. ● Configure LDP GR.

4 Configuring MPLS BFD

i The routers and router icons described in this chapter refer to general routers as well as Layer-3 switches running routing protocols. We use "router series" or "switch series" to refer to specific devices.

4.1 Overview

MPLS Bidirectional Forwarding Detection (BFD) is implemented based on *BFD for MPLS LSPs* defined by the IETF. As a part of BFD application, it describes a method of detecting MPLS LSPs.

i For details about BFD, see *Configuring BFD*.

On an MPLS network, the following methods are used to detect LSP failures:

- MPLS Operation Administration and Maintenance (OAM) mechanism: This mechanism can detect, determine, and locate defects or failures of MPLS networks. However, the MPLS OAM mechanism is being standardized, and other OAM mechanisms have been applied to networks for only a short time. Therefore, perhaps not all devices support OAM.
- Hello packet mechanism of the MPLS signaling protocol: It takes a long time (usually several seconds) for this mechanism to detect failures. Therefore, this mechanism will cause massive traffic loss.

With the following features, MPLS BFD can solve the problems:

- Interoperability: MPLS BFD provides a uniform detection mechanism for the entire network.
- Quick detection: MPLS BFD enables light-load quick detection, enables backup forwarding paths quickly, and improves the reliability of MPLS networks.
- BFD can be used to detect failures of the data plane on an MPLS LSP, and BFD packets have fixed formats. Therefore, BFD can be implemented on hardware and traverse firewalls.

4.2 Applications

Application	Description
Detecting Static LSPs by Using BFD	Detects the connectivity of static LSPs by using Bidirectional Forwarding Detection (BFD). Correlates static LSPs with BFD. When a static LSP is in Down state, the LSP is no longer used as a forwarding path.
Detecting LDP LSPs by Using BFD	Detects the connectivity of LDP LSPs by using BFD. Correlates LDP LSPs with BFD. When an LDP LSP is in Down state, the LSP is no longer used as a forwarding path.
Detecting BGP LSPs by Using BFD	Detects the connectivity of BGP LSPs by using BFD. Correlates BGP LSPs with BFD. When a BGP LSP is in Down state, the LSP is no longer used as a forwarding path.

4.2.1 Detecting Static LSPs by Using BFD

Scenario

If static LSPs are used on an MPLS network, you can detect the connectivity of static LSPs by using BFD.

Take PE1 in the following figure as an example. An LSP is unidirectional and BFD is bidirectional, so two LSPs are required for detection. (LSPs in both directions can share one path or use different paths. The following figure shows the latter.)

- When static LSP1 is faulty, BFD for PE2 will perceive the fault and use static LSP2 to inform PE1 of such fault. BFD sessions will be in Down state, and PE1 will delete the Facsimile Transmission Network (FTN) of static LSP1 to avoid selecting LSP1 as a forwarding path.
- When static LSP1 is recovered, the BFD sessions between PE1 and PE2 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 4-1

Remarks	Static LSP1 is used to transmit data from PE1 to PE2. Static LSP2 is used to transmit data from PE2 to PE1. BFD-based LSP1 detection is configured on PE1. BFD-based LSP2 detection is configured on PE2.
---------	--

Deployment

- Run OSPF on the entire network for unicast routing.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Configure the static FTN connected to PE2 on PE1, and set P1 as the next hop. Configure the static ILM connected to PE2 on P1, and establish static LSP1.
- Configure the static FTN connected to PE1 on PE2, and set P2 as the next hop. Configure the static ILM connected to PE1 on P2, and establish static LSP2.
- Configure BFD-based static LSP detection on PE1 and PE2 respectively.

4.2.2 Detecting LDP LSPs by Using BFD

Scenario

If LSPs are established through LDP on anMPLS network, you can detect the connectivity of LDP LSPs by using BFD.

Take PE1 in the following figure as an example (the two LSPs share the same path):

- When LSP1 is faulty, BFD for PE2 will perceive the fault. If LDP LSP2 is available, BFD for PE1 will be informed of such fault; if LSP2 is unavailable, BFD for PE1 will perceive such fault. In both cases, BFD sessions will be in Down state, and PE1 will delete the FTN of LSP1 to avoid selecting LSP1 as a forwarding path.
- When LDP LSP1 is recovered, the BFD sessions between PE1 and PE2 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 4-2

Remarks	LDP LSP1 is used to transmit data from PE1 to PE2. LDP LSP2 is used to transmit data from PE2 to PE1. BFD-based LDP LSP detection is configured on PE1. BFD-based LDP LSP detection is configured on PE2.
---------	--

Deployment

- Run OSPF on the entire network for unicast routing.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Enable LDP on the entire network to establish LDP LSPs.
- Configure BFD-based LDP LSP detection on PE1 and PE2 respectively.

4.2.3 Detecting BGP LSPs by Using BFD

Scenario

If LSPs are established throughBGP on anMPLS network, you can detect the connectivity of BGP LSPs by using BFD.

Take PE1 in the following figure as an example (the two LSPs share the same path):

- When BGP LSP1 is faulty, BFD for PE3 will perceive the fault. If BGP LSP2 is available, BFD for PE1 will be informed of such fault; if LSP2 is unavailable, BFD for PE1 will perceive such fault. In both cases, BFD sessions will be in Down state, and PE1 will delete the FTN of LSP1 to avoid selecting LSP1 as a forwarding path.
- When BGP LSP1 is recovered, the BFD sessions between PE1 and PE3 will return to UP state, and PE1 will reassign an FTN to LSP1 so that LSP1 is available again.

Figure 4-3

Remarks	<p>BGP LSP1 is used to transmit data from PE1 to PE3.</p> <p>BGP LSP2 is used to transmit data from PE3 to PE1.</p> <p>BFD-based BGP LSP detection is configured on PE1.</p> <p>BFD-based BGP LSP detection is configured on PE3.</p>
---------	---

Deployment

- Deploy PE1 and PE2 in one Autonomous System (AS), and deploy PE2 and PE3 in the other AS.
- Run OSPF, LDP, and BGP in each AS.
- Run BGP between ASs to assign labels to routes and establish BGP LSPs.
- Enable MPLS forwarding on the entire network to forward MPLS packets.
- Configure BFD-based LSP detection on PE1 and PE3 respectively.

4.3 Features

Basic Concepts

📌 BFD Session

BFD uses local identifier (My Discriminator) and remote identifier (Your Discriminator) to distinguish apart multiple BFD sessions. Identifiers can be configured automatically or manually.

- If identifiers are configured manually, BFD sessions can be established directly.

- If identifiers are automatically configured, before devices establish BFD sessions, local identifiers must be included in LSP Ping echo packets for session negotiation and remote identifiers must be learned.

↘ BFD Mode

Before two devices exchange BFD control packets, they need to establish a BFD session. The control plane and data plane must share the same path. BFD sessions can be operated in two modes:

- Asynchronous mode: Both ends send control packets to each other regularly. If one end fails to receive packets within a specified period of time, it indicates that the session is in Down state.
- Query mode: After a session is established, both ends send control packets to each other only when they need to detect the connectivity. If the recipient does not reply, the sender will consider the session in Down state.

In addition to the preceding modes, BFD defines the echo function. With this function, a device can send customized packets to the peer end. The peer end returns the packets to the sender without processing them. The echo function is applicable to both asynchronous mode and query mode.

 Currently, BFD-LSP correlation supports the asynchronous mode but does not support the query mode or the echo function.

Overview

Feature	Description
Establishing BFD Sessions	Establishes BFD sessions between the devices at both ends of the LSP to be detected.
Correlating BFD with LSPs	When any fault is detected by BFD, the LSP needs to be disabled temporarily and restarted after troubleshooting.

4.3.1 Establishing BFD Sessions

During BFD session initialization, the ingress LSR and egress LSR can be active or passive, which depends on the application scenario. However, at least one of them is active. The following describes two scenarios:

↘ Both Active

As LSPs are unidirectional, the following two scenarios must be considered:

- When packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the other LSP is detected by using BFD.

The ingress LSR sends an LSP Ping echo request packet with a local identifier to the egress LSR. The egress LSR obtains a remote identifier from the received packet. In this way, the egress LSR has both local identifier (generated by the egress LSR) and remote identifier. Then the egress LSR sends a BFD control packet to the ingress LSR. The ingress LSR obtains a remote identifier from the received packet. In this way, the ingress LSR has both local identifier (generated by the ingress LSR) and remote identifier. Then the ingress LSR sends a BFD control packet to the egress LSR. A BFD session is then initialized between both ends.

Note: When receiving an echo request packet, the egress LSR can choose to or not to return an echo reply packet. If the egress LSR returns an echo reply packet, a local identifier (generated by the egress LSR) must be included in the echo reply packet. In this way, the ingress LSR can obtain a remote identifier from both the BFD control packet and the echo reply packet.

 The egress LSR works in a similar way to the ingress LSR.

- When packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the IP address is detected by using BFD (multiple hops exist).

In this case, BFD session can be established only by manually configuring identifiers on the ingress LSR and the egress LSR. That is, after identifiers are configured manually, BFD sessions can be established without identifier negotiation.

One Active, the Other Passive

The active one sends an LSP Ping echo request packet with a local identifier to the passive one. The passive one obtains a remote identifier from the received packet. In this way, the passive one has both local identifier (generated by the passive one) and remote identifier. Then the passive one sends a BFD control packet to the active one. The active one obtains a remote identifier from the received packet. In this way, the active one has both local identifier (generated by the active one) and remote identifier. Then the active one sends a BFD control packet to the passive one. A BFD session is then initialized between both ends.

Note: When receiving an echo request packet, the passive one can choose to or not to return an echo reply packet. If the passive one returns an echo reply packet, a local identifier (generated by the passive one) must be included in the echo reply packet. In this way, the active one can obtain a remote identifier from both the BFD control packet and the echo reply packet.

Before receiving an echo request packet from the active one, the passive one will not send a BFD control packet to the active one.

 Currently, BFD-LSP correlation supports the "both active" mode but does not support the "one active, the other passive" mode.

Working Principle

The following describes the process of BFD session establishment in the first scenario (when packets are sent from the ingress LSR to the egress LSR, the LSP is detected by using BFD; when packets are sent from the egress LSR to the ingress LSR, the other LSP is detected by using BFD) when both ends are active.

Figure 4-4

- Before enabling BFD, both ingress LSR and egress LSR must learn remote identifiers and ensure that LSPs are in Up state. As shown in the figure, the ingress LSR sends an LSP Ping echo request packet with a local identifier to the egress LSR. Upon receipt of the echo request packet, the egress LSR returns an echo reply packet with a local identifier (generated by the egress LSR) to the ingress LSR. The case is similar with the egress LSR. Note: When no identifier is specified, both ends need to learn the identifier of the other through an LSP Ping echo packet. If local and remote identifiers are specified by both ends, the devices will skip to the next step. For information on identifier configuration, see the section "Correlating BFD with LSPs".
- The ingress LSR and egress LSR enable BFD. They are in Down state initially. BFD packets are in Down state.
- The egress LSR receives the BFD packets and locally switches BFD to Init state. The BFD packets are in Init state.
- The egress LSR no longer processes BFD packets that are in Down state.
- The case is similar with the ingress LSR.
- The egress LSR receives BFD packets that are in Init state and locally switches BFD to Up state.
- The case is similar with the ingress LSR.
- The Up state indicates that BFD sessions are established successfully.

Related Configuration

- [Configuring BFD Session Parameters on an Interface](#)

By default, BFD session parameters are not configured on an interface.

By running the **bfd interval** command, you can configure or cancel BFD session parameters on an interface.

The BFD sessions for detecting LSPs can be established only when the **bfd interval** command is configured on the LSP interface, the command for BFD-based LSP detection described in the next section is configured, and the corresponding LSPs exist. The speed of fault detection is determined by the session parameters designated by the **bfd interval** command.

4.3.2 Correlating BFD with LSPs

BFD sessions are distinguished apart through local identifier (My Discriminator) and remote identifier (Your Discriminator). Based on the identifier specification mode, BFD and LSP can be correlated in two modes:

- Manual mode

If identifiers are configured manually, BFD sessions can be established directly.

- Automatic mode

If identifiers are automatically configured, before devices establish BFD sessions, local identifiers must be included in LSP Ping packets for session negotiation and remote identifiers must be learned.

Based on types of LSPs, BFD-LSP correlation includes BFD-based static LSP detection, BFD-based LDP LSP detection, and BFD-based BGP LSP detection.

Working Principle

↘ BFD-based Static LSP Detection

BFD-based static LSP detection can be configured manually or automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional static LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with static LSPs

After the detection method is selected, BFD sessions will be established and in UP state. Then, if any fault is detected by BFD, BFD sessions will be in Down state; if the configuration command has the **process-state** parameter, Ingress LSR will delete the FTN of the faulty LSP so that such LSP will not be selected as a forwarding path. If the fault is removed, BFD sessions will return to UP state, and Ingress LSR will re-add the FTN of such LSP so that such LSP will be reused as a forwarding path.

↘ BFD-based LDP LSP Detection

BFD-based LDP LSP detection can be configured manually or automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional LDP LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with LDP LSPs

BGP LSPs are used for basic VPN/PW services. Therefore, BFD-based LDP LSP detection detects failures of VPN/PW. By using this function, you can quickly detect various MPLS-based network applications such as VPN Fast Reroute (FRR) and PW FRR, thereby protecting services and improving reliability of MPLS networks. LDP LSPs and static LSPs share the same process of BFD-based fault detection, process of recovery, and relevant processing.

📌 BFD-based BGP LSP Detection

The function can be configured both manually and automatically. An LSP is a unidirectional link, while BFD is a bidirectional detection mechanism. Therefore, when detecting unidirectional BGP LSPs by using BFD, you can select any of the following methods to detect their backward links:

- Detecting backward links with IP
- Detecting backward links with BGP LSPs

BGP LSPs are used for basic VPN/PW services. Therefore, BFD-based BGP LSP detection detects faults of VPN/PW. By using this function, you can quickly detect various MPLS-based network applications such as VPN Fast Reroute (FRR) and PW FRR, thereby protecting services and improving reliability of MPLS networks. LDP LSPs, static LSPs and LDP LSPs share the same process of BFD-based fault detection, process of recovery, and relevant processing.

Related Configuration

📌 Configuring BFD-based Static LSP Detection

By default, BFD-based static LSP detection is disabled.

Run the **bfd bind static-lsp** command to enable BFD-based static LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

📌 Configuring BFD-based LDP LSP Detection

By default, BFD-based LDP LSP detection is disabled.

Run the **bfd bind ldp-lsp** command to enable BFD-based LDP LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

📌 Configuring BFD-based BGP LSP Detection

By default, BFD-based BGP LSP detection is disabled.

Run the **bfd bind bgp-lsp** command to enable BFD-based BGP LSP detection.

The number of BFD sessions is limited. If the number of BFD sessions submitted by a user exceeds the maximum allowed, the system will generate log information to prompt the user.

4.4 Configuration

Configuration items	Description and Command	
Configuring BFD-based Static LSP Detection	 (Mandatory) It is used to detect the connectivity of static LSPs by using BFD.	
	bfd bind static-lsp	Configures BFD-based static LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.
Configuring BFD-based LDP LSP Detection	 (Mandatory) It is used to detect the connectivity of LDP LSPs by using BFD.	
	bfd bind ldp-lsp	Configures BFD-based LDP LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.
Detecting BGP LSPs by Using BFD	 (Mandatory) It is used to detect the connectivity of BGP LSPs by using BFD.	
	bfd bind bgp-lsp	Configures BFD-based BGP LSP detection.
	bfd bind backward-lsp-with-ip	Configures BFD-based detection of backward LSPs with IP.

4.4.1 Configuring BFD-based Static LSP Detection

Configuration Effect

The connectivity of static LSPs can be detected by using BFD. Correlating static LSPs with BFD can prevent a private route from using a faulty static LSP as a forwarding path.

Notes

-  Only host-routed static LSPs can be detected by using BFD.
-  In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure **process-state**.

Before configuring BFD-based static LSP detection, you need to:

- Enable MPLS.
- Configure static LSPs.

Before configuring BFD-based static LSP detection, you need to configure the following:

- Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
- Backward link detection
- BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

Configuring BFD for Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based static LSP detection and process the BFD session state. If BFD-based static LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based static LSP detection must be configured in the same way at both ends.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

Configuring BFD for Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of the backward LSP (route if IP is used).
- Configure BFD-based static LSP detection. Do not process the BFD session state. If BFD-based static LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based static LSP detection must be configured in the same way at both ends.

Or:

- Configure BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

Related Commands

Configuring BFD-based Static LSP Detection

Command	bfd bind static-lsp peer-ip <i>ip-address</i> source-ip <i>ip-address</i> [local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i>] [process-state]
Parameter Description	<p>peer-ip<i>ip-address</i>: Indicates the peer IP address of the static LSP bound with BFD sessions.</p> <p>source-ip<i>ip-address</i>: Indicates the source IP address of BFD packets.</p> <p>local-discriminator<i>discr-value</i>: Configures the local identifier of a BFD session. The value ranges from 1 to 8191.</p> <p>remote-discriminator<i>discr-value</i>: Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.</p> <p>process-state: Processes the BFD session state. In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure</p>

	process-state.
Command Mode	Global configuration mode
Usage Guide	<ul style="list-style-type: none"> ● This command can be run on the ingress node of the LSP. ● If BFD has been configured, BFD configuration items cannot be established. After BFD is configured, if a static LSP exists, BFD sessions will be immediately created; if no static LSP exists, BFD sessions will not be created until a static LSP exists. ● If a static LSP is deleted, the BFD sessions bound with the LSP will be deleted. However, configuration items of the BFD sessions will be retained. When a static LSP exists, BFD sessions will be re-created. ● You can configure local and remote identifiers for BFD sessions. If no local identifier is configured, the system will automatically elect a local identifier. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs. ● After BFD sessions are established, identifiers cannot be modified. ● The system regularly queries submitted BFD configuration items to establish BFD sessions. ● The number of BFD sessions is limited. If the number of requested BFD sessions exceeds the upper limit, the system will generate a log to prompt you.

📌 **Configuring BFD-based Detection of Backward LSPs with IP**

Command	bfd bind backward-lsp-with-ip peer-ip <i>ip-address</i> [vrf <i>vrf-name</i>] interface <i>interface-type</i> <i>interface-number</i> [source-ip <i>ip-address</i>] { local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i> }
Parameter Description	<p>peer-ip<i>ip-address</i>: Indicates the peer IP address of the LSP bound with BFD sessions.</p> <p>vrf<i>vrf-name</i>: Indicates the name of VRF bound with BFD sessions.</p> <p>interface <i>interface-type interface-number</i>: Configures the interface type and number.</p> <p>source-ip<i>ip-address</i>: Indicates the source IP address of BFD packets.</p> <p>local-discriminator<i>discr-value</i>: Configures the local identifier of a BFD session. The value ranges from 1 to 8191.</p> <p>remote-discriminator<i>discr-value</i>: Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.</p>
Command Mode	Global configuration mode
Usage Guide	Configures BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

Common Errors

- BFD sessions are not configured on the outbound interface of the LSP.
- The interface on which BFD sessions are configured is not the outbound interface of the LSP.
- Static FTN/ILM entries do not take effect.
- The LSP is incomplete.
- The global **mpls ip** command is not run.
- The **label-switching** command for enabling MPLS forwarding on the interface is not run.
- The source address and destination address of the BFD-detected devices at both ends of an LSP are not matched.
- The identifiers configured (manually) for the BFD-detected devices at both ends of an LSP are not matched.
- Forward Error Correction (FEC) corresponding to the detected LSP is not routed by the host.

4.4.2 Configuring BFD-based LDP LSP Detection

Configuration Effect

- The connectivity of LDP LSPs can be detected by using BFD. Correlating an LDP LSP with BFD can prevent a private route from using the LSP as a forwarding path when it is in Down state.

Notes

- Only host-routed LDP LSPs can be detected by using BFD.
- One LSP can be bound with only one BFD session.

- An LDP LSP must be bound with BFD at its ingress.
- In application scenarios where failures need to be detected by using BFD, for example, the BFD-LSP correlation scenario, you need to configure **process-state**.
- Before configuring BFD-based LDP LSP detection, you need to:
 1. Enable MPLS.
 2. Enable LDP.
- Before configuring BFD-based LDP LSP detection, you need to configure the following:
 1. Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
 2. Backward link detection
 3. BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

▾ Configuring BFD for the Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based LDP LSP detection and process the BFD session state. If BFD-based LDP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based LDP LSP detection must be configured in the same way at both ends.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

▾ Configuring BFD for Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based LDP LSP detection. Do not process the BFD session state. If BFD-based LDP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based LDP LSP detection must be configured in the same way at both ends.

Or:

- Configures BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

 Only host-routed LDP LSPs can be detected by using BFD.

 One LSP can be bound with only one BFD session.

 An LDP LSP must be bound with BFD at its ingress.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

Common Errors

- BFD sessions are not configured on the outbound interface of an LSP.
- The interface on which BFD sessions are configured is not the outbound interface of an LSP.
- FTN/ILM entries are not assigned through LDP.
- An LSP is incomplete.
- The global **mpls ip** command is not run.
- The **label-switching** command for enabling MPLS forwarding on an interface is not run.
- The source address and destination address of the BFD-detected devices at both ends of an LSP are not matched.
- The identifiers configured (manually) for the BFD-detected devices at both ends of an LSP are not matched.
- The forwarding equivalence class (FEC) corresponding to the detected LSP is not routed by the host.

4.4.3 Configuring BFD-based BGP LSP Detection

Configuration Effect

- The connectivity of BGP LSPs can be detected by using BFD. By correlating a BGP LSP with BFD, you can prevent the private route from using the LSP as a forwarding path when it is in Down state.

Notes

- Only host-routed BGP LSPs can be detected by using BFD.

- One LSP can be bound with only one BFD session.
- A BGP LSP must be bound with BFD at its ingress.
- Before configuring BFD-based BGP LSP detection, you need to:
 1. Enable MPLS.
 2. Assign labels via BGP.
- Before configuring BFD-based BGP LSP detection, you need to configure the following:
 1. Local identifier (My Discriminator) and remote identifier (Your Discriminator) of a BFD session
 2. Backward link detection
 3. BFD session parameters: interval for sending BFD control packets, interval for receiving BFD control packets, and BFD control packet detection multiplier

Configuration Steps

↳ Configuring BFD for the Ingress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based BGP LSP detection and process the status of BFD sessions. If BFD is configured manually for Ingress LSR, it must be configured manually for Egress LSR. That is to say, configurations at both ends must be consistent.

 If identifiers are configured manually, local and remote identifiers configured on the ingress LSR must match those configured on the egress LSR.

↳ Configuring BFD for the Egress LSR

- Mandatory.
- Configure BFD sessions on the outbound interface of an LSP.
- Configure BFD-based BGP LSP detection. Do not process the BFD session state. If BFD-based BGP LSP detection is configured manually on the ingress LSR, it must be configured manually on the egress LSR. That is, BFD-based BGP LSP detection must be configured in the same way at both ends.

Or:

- Configures BFD-based detection of backward LSPs with IP. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs.

 If identifiers are configured manually, local and remote identifiers configured on the egress LSR must match those configured on the ingress LSR.

 Only host-routed BGP LSPs can be detected by using BFD.

 One LSP can be bound with only one BFD session.

 A BGP LSP must be bound with BFD at its ingress.

Verification

Run the **show bfd neighbors** command to check whether BFD sessions are in Up state.

📌 Detecting the Connectivity of BGP LSPs by Using BFD

Command	bfd bind bgp-lsp peer-ip <i>ip-address</i> source-ip <i>ip-address</i> [local-discriminator <i>discr-value</i> remote-discriminator <i>discr-value</i>]
Parameter Description	peer-ip <i>ip-address</i> : Indicates the sink IP address of the BGP LSP bound with BFD sessions. source-ip <i>ip-address</i> : Indicates the source IP address of BFD packets. local-discriminator <i>discr-value</i> : Configures the local identifier of a BFD session. The value ranges from 1 to 8191. remote-discriminator <i>discr-value</i> : Configures the remote identifier of the BFD session. The value ranges from 1 to 8191.
Command Mode	Global configuration mode
Usage Guide	<ul style="list-style-type: none"> ● Enable global MPLS forwarding on each node, and enable the forwarding of MPLS label packets on the interface. Configure IBGP and assign labels via BGP between PE1 and PE2. Configure EBGP and assign labels via BGP between PE2 and PE3. Configure BFD-based BGP LSP1 detection on PE1. This command can be run on the ingress node of the LSP. ● If BFD has been configured, BFD configuration items cannot be established. After BFD is configured, if a BGP LSP exists, BFD sessions will be immediately created; if no BGP LSP exists, BFD sessions will not be created until an LSP exists. ● If a BGP LSP is deleted, the BFD sessions bound with the LSP will be deleted. However, configuration items of the BFD sessions will be retained. When a BGP LSP exists, BFD sessions will be re-created. ● You can configure local and remote identifiers for BFD sessions. If no local identifier is configured, the system will automatically elect a local identifier. If backward LSPs with IP are detected, local and remote identifiers must be configured manually for forward LSPs. ● After BFD sessions are established, identifiers cannot be modified. ● The system regularly queries submitted BFD configuration items to establish BFD sessions. ● The number of BFD sessions is limited. If the number of requested BFD sessions exceeds the upper limit, the system will generate a log to prompt you.

📌 Configuring BFD-based Detection of Backward LSPs with IP

1 Configuring AAA

1.1 Overview

Authentication, authorization, and accounting (AAA) provides a unified framework for configuring the authentication, authorization, and accounting services. Nodexon Networks devices support the AAA application.

AAA provides the following services in a modular way:

Authentication: Refers to the verification of user identities for network access and network services. Authentication is classified into local authentication and authentication through Remote Authentication Dial In User Service (RADIUS) and Terminal Access Controller Access Control System+ (TACACS+).

Authorization: Refers to the granting of specific network services to users according to a series of defined attribute-value (AV) pairs. The pairs describe what operations users are authorized to perform. AV pairs are stored on network access servers (NASs) or remote authentication servers.

Accounting: Refers to the tracking of the resource consumption of users. When accounting is enabled, NASs collect statistics on the network resource usage of users and send them in AV pairs to authentication servers. The records will be stored on authentication servers, and can be read and analyzed by dedicated software to realize the accounting, statistics, and tracking of network resource usage.

AAA is the most fundamental method of access control. Nodexon Networks also provides other simple access control functions, such as local username authentication and online password authentication. Compared to them, AAA offers higher level of network security.

AAA has the following advantages:

- Robust flexibility and controllability
- Scalability
- Standards-compliant authentication
- Multiple standby systems

1.2 Applications

Application	Description
Configuring AAA in a Single-Domain Environment	AAA is performed for all the users in one domain.
Configuring AAA in a Multi-Domain Environment	AAA is performed for the users in different domains by using different methods.

1.2.1 Configuring AAA in a Single-Domain Environment

Scenario

In the network scenario shown in Figure 1-1, the following application requirements must be satisfied to improve the security management on the NAS:

1. To facilitate account management and avoid information disclosure, each administrator has an individual account with different username and password.
2. Users must pass identity authentication before accessing the NAS. The authentication can be in local or centralized mode. It is recommended to combine the two modes, with centralized mode as active and local mode as standby. As a result, users must undergo authentication by the RADIUS server first. If the RADIUS server does not respond, it turns to local authentication.
3. During the authentication process, users can be classified and limited to access different NASs.
4. Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
5. The AAA records of users are stored on servers and can be viewed and referenced for auditing. (The TACACS+ server in this example performs the accounting.)

Figure 1-1

Remarks

User A, User B, and User C are connected to the NAS in wired or wireless way.
 The NAS is an access or convergence switch.
 The RADIUS server can be the Windows 2000/2003 Server (IAS), UNIX system component, and dedicated server software provided by a vendor.
 The TACACS+ server can be the dedicated server software provided by a vendor.

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Configure the authentication service on the NAS.

- Configure the authorization service on the NAS.
- Configure the accounting service on the NAS.

1.2.2 Configuring AAA in a Multi-Domain Environment

Scenario

Configure the domain-based AAA service on the NAS.

- A user can log in by entering the username PC1@Nodexon.net or PC2@Nodexon.com.cn and correct password on an 802.1X client.
- Permission management: Users managed are classified into Super User and Common User. Super users have the rights to view and configure the NAS, and common users are only able to view NAS configuration.
- The AAA records of users are stored on servers and can be viewed and referenced for auditing.

Figure 1-2

Remarks	<p>The clients with the usernames PC1@Nodexon.net and PC2@Nodexon.com.cn are connected to the NAS in wired or wireless way.</p> <p>The NAS is an access or convergence switch.</p> <p>The Security Accounts Manager (SAM) server is a universal RADIUS server provided by Nodexon Networks.</p>
----------------	---

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Define an AAA method list on the NAS.
- Enable domain-based AAA on the NAS.
- Create domains and AV sets on the NAS.

1.3 Features

Basic Concepts

Local Authentication and Remote Server Authentication

Local authentication is the process where the entered passwords are verified by the database on the NAS.

Remote server authentication is the process where the entered passwords are checked by the database on a remote server. It is mainly implemented by the RADIUS server and TACACS+ server.

Method List

AAA is implemented using different security methods. A method list defines a method implementation sequence. The method list can contain one or more security protocols so that a standby method can take over the AAA service when the first method fails. On Nodexon devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a security method responds or all the security methods in

the list are tried out. Authentication fails if no method in the list responds.

A method list contains a series of security methods that will be queried in sequence to verify user identities. It allows you to define one or more security protocols used for authentication, so that the standby authentication method takes over services when the active security method fails. On Nodexon devices, the first method in the list is tried in the beginning and then the next is tried one by one if the previous gives no response. This method selection process continues until a method responds

or all

 The next authentication method proceeds on Nodexon devices only when the current method does not respond. When a method denies user access, the authentication process ends without trying other methods.

Figure 1-3

Figure 1-3 shows a typical AAA network topology, where two RADIUS servers (R1 and R2) and one NAS are deployed. The NAS can be the client for the RADIUS servers.

Assume that the system administrator defines a method list, where the NAS selects R1 and R2 in sequence to obtain user identity information and then accesses the local username database on the server. For example, when a remote PC user initiates dial-up access, the NAS first queries the user's identity on R1. When the authentication on R1 is completed, R1 returns an Accept response to the NAS. Then the user is permitted to access the Internet. If R1 returns a Reject response, the user is denied Internet access and the connection is terminated. If R1 does not respond, the NAS considers that the R1 method times out and continues to query the user's identity on R2. This process continues as the NAS keeps trying the remaining authentication methods, until the user request is authenticated, rejected, or terminated. If all the authentication methods are responded with Timeout, authentication fails and the connection will be terminated.

-  The Reject response is different from the Timeout response. The Reject response indicates that the user does not meet the criteria of the available authentication database and therefore fails in authentication, and the Internet access request is denied. The Timeout response indicates that the authentication server fails to respond to the identity query.

When detecting a timeout event, the AAA service proceeds to the next method in the list to continue the authentication process.

-  This document describes how to configure AAA on the RADIUS server. For details about the configuration on the TACACS+ server, see the *Configuring TACACS+*.

AAA Server Group

You can define an AAA server group to include one or more servers of the same type. If the server group is referenced by a method list, the NAS preferentially sends requests to the servers in the referenced server group when the method list is used to implement AAA.

VRF-Enabled AAA Group

Virtual private networks (VPNs) enable users to share bandwidths securely on the backbone networks of Internet service providers (ISPs). A VPN is a site set consisting of shared routes. An STA site connects to the network of an ISP through one or multiple interfaces. AAA supports assigning a VPN routing forwarding (VRF) table to each user-defined server group.

When AAA is implemented by the server in a group assigned with a VRF table, the NAS sends request packets to the remote servers in the server group. The source IP address of request packets is an address selected from the VRF table according to the IP addresses of the remote servers.

If you run the **ip radius/tacacs+ source-interface** command to specify the source interface for the request packets, the IP address obtained from the source interface takes precedence over the source IP address selected from the VRF table.

Overview

Feature	Description
AAA Authentication	Verifies whether users can access the Internet.
AAA Authorization	Determines what services or permissions users can enjoy.
AAA Accounting	Records the network resource usage of users.
Multi-Domain AAA	Creates domain-specific AAA schemes for 802.1X stations (STAs) in different domains.

1.3.1 AAA Authentication

Authentication, authorization, and accounting are three independent services. The authentication service verifies whether users can access the Internet. During authentication, the username, password, and other user information are exchanged between devices to complete users' access or service requests. You can use only the authentication service of AAA.

-  To configure AAA authentication, you need to first configure an authentication method list. Applications perform authentication according to the method list. The method list defines the types of authentication and the sequence in which they are performed. Authentication methods are implemented by specified applications. The only exception is the default method list. All applications use the default method list if no method list is configured.

AAA Authentication Scheme

- No authentication (**none**)

The identity of trusted users is not checked. Normally, the no-authentication (None) method is not used.

- Local authentication (**local**)

Authentication is performed on the NAS, which is configured with user information (including usernames, passwords, and AV pairs). Before local authentication is enabled, run the **username password/secret** command to create a local user database.

- Remote server group authentication (**group**)

Authentication is performed jointly by the NAS and a remote server group through RADIUS or TACACS+. A server group consists of one or more servers of the same type. User information is managed centrally on a remote server, thus realizing multi-device centralized and unified authentication with high capacity and reliability. You can configure local authentication as standby to avoid authentication failures when all the servers in the server group fail.

AAA Authentication Types

Nodexon products support the following authentication types:

- Login authentication

Users log in to the command line interface (CLI) of the NAS for authentication through Secure Shell (SSH), Telnet, and File Transfer Protocol (FTP).

- Enable authentication

After users log in to the CLI of the NAS, the users must be authenticated before CLI permission update. This process is called Enable authentication (in Privileged EXEC mode).

- Dot1X (IEEE802.1X) authentication

Dot1X (IEEE802.1X) authentication is performed for users that initiate dial-up access through IEEE802.1X.

- Web (second generation portal) authentication

Web authentication is performed by the second generation portal server.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authentication Scheme

By default, no AAA authentication scheme is configured.

Before you configure an AAA authentication scheme, determine whether to use local authentication or remote server authentication. If the latter is to be implemented, configure a RADIUS or TACACS+ server in advance. If local authentication is selected, configure the local user database information on the NAS.

Configuring an AAA Authentication Method List

By default, no AAA authentication method list is configured.

Determine the access mode to be configured in advance. Then configure authentication methods according to the access mode.

1.3.2 AAA Authorization

AAA authorization allows administrators to control the services or permissions of users. After AAA authorization is enabled, the NAS configures the sessions of users according to the user configuration files stored on the NAS or servers. After authorization, users can use only the services or have only the permissions permitted by the configuration files.

AAA Authorization Scheme

- Direct authorization (**none**)

Direct authorization is intended for highly trusted users, who are assigned with the default permissions specified by the NAS.

- Local authorization (**local**)

Local authorization is performed on the NAS, which authorizes users according to the AV pairs configured for local users.

- Remote server-group authorization (**group**)

Authorization is performed jointly by the NAS and a remote server group. You can configure local or direct authorization as standby to avoid authorization failures when all the servers in the server group fail.

AAA Authorization Types

- EXEC authorization

After users log in to the CLI of the NAS, the users are assigned with permission levels (0 to 15).

- Config-commands authorization

Users are assigned with the permissions to run specific commands in configuration modes (including the global configuration mode and sub-modes).

- Console authorization

After users log in through consoles, the users are authorized to run commands.

- Command authorization

Authorize users with commands after login to the CLI of the NAS.

- Network authorization

After users access the Internet, the users are authorized to use the specific session services. For example, after users access the Internet through PPP and Serial Line Internet Protocol (SLIP), the users are authorized to use the data service, bandwidth, and timeout service.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↘ **Configuring an AAA Authorization Scheme**

By default, no AAA authorization scheme is configured.

Before you configure an AAA authorization scheme, determine whether to use local authorization or remote server-group authorization. If remote server-group authorization needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local authorization needs to be implemented, configure the local user database information on the NAS.

↘ **Configuring an AAA Authorization Method List**

By default, no AAA authorization method list is configured.

Determine the access mode to be configured in advance. Then configure authorization methods according to the access mode.

1.3.3 AAA Accounting

In AAA, accounting is an independent process of the same level as authentication and authorization. During the accounting process, start-accounting, update-accounting, and end-accounting requests are sent to the configured accounting server, which records the network resource usage of users and performs accounting, audit, and tracking of users' activities.

In AAA configuration, accounting scheme configuration is optional.

↘ **AAA Accounting Schemes**

- No accounting (**none**)

Accounting is not performed on users.

- Local accounting (**local**)

Accounting is completed on the NAS, which collects statistics on and limits the number of local user connections. Billing is not performed.

- Remote server-group accounting (**group**)

Accounting is performed jointly by the NAS and a remote server group. You can configure local accounting as standby to avoid accounting failures when all the servers in the server group fail.

↘ **AAA Accounting Types**

- EXEC accounting

Accounting is performed when users log in to and out of the CLI of the NAS.

- Command accounting

Records are kept on the commands that users run on the CLI of the NAS.

- Network accounting

Records are kept on the sessions that users set up after completing 802.1X and Web authentication to access the Internet.

Related Configuration

↳ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↳ Configuring an AAA Accounting Scheme

By default, no AAA accounting method is configured.

Before you configure an AAA accounting scheme, determine whether to use local accounting or remote server-group accounting. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. If local accounting needs to be implemented, configure the local user database information on the NAS.

↳ Configuring an AAA Accounting Method List

By default, no AAA accounting method list is configured.

Determine the access mode to be configured in advance. Then configure accounting methods according to the access mode.

1.3.4 Multi-Domain AAA

In a multi-domain environment, the NAS can provide the AAA services to users in different domains. The user AVs (such as usernames and passwords, service types, and permissions) may vary with different domains. It is necessary to configure domains to differentiate the user AVs in different domains and configure an AV set (including an AAA service method list, for example, RADIUS) for each domain.

Our products support the following username formats:

1. userid@domain-name
2. domain-name\userid
3. userid.domain-name
4. userid

The fourth format (userid) does not contain a domain name, and it is considered to use the **default** domain name.

The NAS provides the domain-based AAA service based on the following principles:

- Resolves the domain name carried by a user.
- Searches for the user domain according to the domain name.
- Searches for the corresponding AAA method list name according to the domain configuration information on the NAS.
- Searches for the corresponding method list according to the method list name.
- Provides the AAA services based on the method list.

 If any of the preceding procedures fails, the AAA services cannot be provided.

Figure 1-4 shows the typical multi-domain topology.

Figure 1-4

Related Configuration

↳ Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

↳ Configuring an AAA Method List

By default, no AAA method list is configured.

For details, see section 5.2.1, section 5.2.2, and section 5.2.3.

↳ Enabling the Domain-Based AAA Service

By default, the domain-based AAA service is disabled.

To enable the domain-based AAA service, run the **aaa domain enable** command.

↳ Creating a Domain

By default, no domain is configured.

To configure a domain, run the **aaa domain domain-name** command.

↳ Configuring an AV Set for a Domain

By default, no domain AV set is configured.

A domain AV set contains the following elements: AAA method lists, the maximum number of online users, whether to remove the domain name from the username, and whether the domain name takes effect.

↳ Displaying Domain Configuration

To display domain configuration, run the **show aaa domain** command.

i The system supports a maximum of 32 domains.

1.4 Configuration

Configuration	Description and Command
Configuring AAA	 Mandatory if user identities need to be verified.

Configuration	Description and Command	
Authentication	aaa new-model	Enables AAA.
	aaa authentication login	Defines a method list of login authentication.
	aaa authentication enable	Defines a method list of Enable authentication.
	aaa authentication dot1x	Defines a method list of 802.1X authentication.
	aaa authentication web-auth	Configures a method list of Web authentication.
	aaa local authentication attempts	Sets the maximum number of login attempts.
	aaa local authentication lockout-time	Sets the maximum lockout time after a login failure.
Configuring AAA Authorization	 Mandatory if different permissions and services need to be assigned to users.	
	aaa new-model	Enables AAA.
	aaa authorization exec	Defines a method list of EXEC authorization.
	aaa authorization commands	Defines a method list of command authorization.
	aaa authorization network	Configures a method list of network authorization.
	authorization exec	Applies EXEC authorization methods to a specified VTY line.
	authorization commands	Applies command authorization methods to a specified VTY line.
Configuring AAA Accounting	 Mandatory if accounting, statistics, and tracking need to be performed on the network resource usage of users.	
	aaa new-model	Enables AAA.
	aaa accounting exec	Defines a method list of EXEC accounting.
	aaa accounting commands	Defines a method list of command accounting.
	aaa accounting network	Defines a method list of network accounting.
	accounting exec	Applies EXEC accounting methods to a specified VTY line.
	accounting commands	Applies command accounting methods to a specified VTY line.
	aaa accounting update	Enables accounting update.
aaa accounting update periodic	Configures the accounting update interval.	

Configuration	Description and Command	
Configuring an AAA Server Group	 Recommended if a server group needs to be configured to handle AAA through different servers in the group.	
	aaa group server	Creates a user-defined AAA server group.
	server	Adds an AAA server group member.
	ip vrf forwarding	Configures the VRF attribute of an AAA server group.
Configuring the Domain-Based AAA Service	 Mandatory if AAA management of 802.1X access STAs needs to be performed according to domains.	
	aaa new-model	Enables AAA.
	aaa domain enable	Enables the domain-based AAA service.
	aaa domain	Creates a domain and enters domain configuration mode.
	authentication dot1x	Associates the domain with an 802.1X authentication method list.
	accounting network	Associates the domain with a network accounting method list.
	authorization network	Associates the domain with a network authorization method list.
	state	Configures the domain status.
	username-format	Configures whether to contain the domain name in usernames.
access-limit	Configures the maximum number of domain users.	

1.4.1 Configuring AAA Authentication

Configuration Effect

Verify whether users are able to obtain access permission.

Notes

- If an authentication scheme contains multiple authentication methods, these methods are executed according to the configured sequence.
 - When the **none** method is used, users can get access even when no authentication method gets response. Therefore, the **none** method is used only as standby.
-  Normally, do not use None authentication. You can use the **none** method as the last optional authentication method in special cases. For example, all the users who may request access are trusted users and the users' work must not be delayed by system faults. Then you can use the **none** method to assign access permissions to these users when the

authentication server does not respond. It is recommended that the local authentication method be added before the **none** method.

- If AAA authentication is enabled but no authentication method is configured and the default authentication method does not exist, users can directly log in to the Console without being authenticated. If users log in by other means, the users must pass local authentication.
- When a user enters the CLI after passing login authentication (the **none** method is not used), the username is recorded. When the user performs Enable authentication, the user is not prompted to enter the username again, because the username that the user entered during login authentication is automatically filled in. However, the user must enter the password previously used for login authentication.
- The username is not recorded if the user does not perform login authentication when entering the CLI or the **none** method is used during login authentication. Then, a user is required to enter the username each time when performing Enable authentication.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Defining a Method List of Login Authentication

- Run the **aaa authentication login** command to configure a method list of login authentication.
- This configuration is mandatory if you need to configure a login authentication method list (including the configuration of the default method list).
- By default, no method list of login authentication is configured.

↳ Defining a Method List of Enable Authentication

- Run the **aaa authentication enable** command to configure a method list of Enable authentication.
- This configuration is mandatory if you need to configure an Enable authentication method list. (You can configure only the default method list.)
- By default, no method list of Enable authentication is configured.

↳ Defining a Method List of 802.1X Authentication

- Run the **aaa authentication dot1x** command to configure a method list of 802.1X authentication.
- This configuration is mandatory if you need to configure an 802.1X authentication method list (including the configuration of the default method list).
- By default, no method list of 802.1X authentication is configured.

↳ Defining a Method List of Web Authentication

- Run the **aaa authentication web-auth** command to configure a method list of Web authentication.
- This configuration is mandatory if you need to configure a Web authentication method list (including the configuration of the default method list).
- By default, no method list of Web authentication is configured.

▾ Setting the Maximum Number of Login Attempts

- Optional.
- By default, a user is allowed to enter passwords up to three times during login.

▾ Setting the Maximum Lockout Time After a Login Failure

- Optional.
- By default, a user is locked for 15 minutes after entering wrong passwords three times.

Verification

- Run the **show aaa method-list** command to display the configured method lists.
- Run the **show aaa lockout** command to display the settings of the maximum number of login attempts and the maximum lockout time after a login failure.
- Run the **show running-config** command to display the authentication method lists associated with login authentication and 802.1X authentication.

Related Commands

▾ Enabling AAA

Command	aaa new-model
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

▾ Defining a Method List of Login Authentication

Command	aaa authentication login { default list-name } method1 [method2...]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a login authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from local, none, group, and subs. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p>

	<p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p> <p>subs: Indicates that the subs database is used for authentication.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA login authentication service is enabled on the NAS, users must perform login authentication negotiation through AAA. Run the aaa authentication login command to configure the default or optional method lists for login authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p> <p>After you configure login authentication methods, apply the methods to the VTY lines that require login authentication; otherwise, the methods will not take effect.</p>

▾ Defining a Method List of Enable Authentication

Command	aaa authentication enable default <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of an Enable authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from enable, local, none, and group. A method list contains up to four methods.</p> <p>enable: Indicates that the password that is configured using the enable command is used for authentication.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA login authentication service is enabled on the NAS, users must perform Enable authentication negotiation through AAA. Run the aaa authentication enable command to configure the default or optional method lists for Enable authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p>

▾ Defining a Method List of 802.1X Authentication

Command	aaa authentication dot1x { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of an 802.1X authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from local, none, and group. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS server group is supported.</p>
Command	Global configuration mode

Mode	
Usage Guide	<p>If the AAA 802.1X authentication service is enabled on the NAS, users must perform 802.1X authentication negotiation through AAA. Run the aaa authentication dot1x command to configure the default or optional method lists for 802.1X authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p>

▾ Defining a Method List of PPP, Web, iPortal or SSL VPN Authentication

Command	aaa authentication { web-auth } { default list-name } method1 [method2...]
Parameter Description	<p>web-auth: Configures a method list of Web authentication.</p> <p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a PPP authentication method list in characters.</p> <p><i>method:</i> Indicates authentication methods from local, none, group, and subs. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for authentication.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for authentication. Currently, the RADIUS and TACACS+ server groups are supported.</p> <p>subs: Specifies the SUBS authentication method using the SUBS database.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the AAA PPP authentication service is enabled on the NAS, users must perform PPP authentication negotiation through AAA. Run the aaa authentication ppp command to configure the default or optional method lists for PPP authentication.</p> <p>In a method list, the next method is executed only when the current method does not receive response.</p>

▾ Setting the Maximum Number of Login Attempts

Command	aaa local authentication attempts max-attempts
Parameter Description	<i>max-attempts:</i> Indicates the maximum number of login attempts. The value ranges from 1 to 2,147,483,647.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum number of times a user can attempt to login.

▾ Setting the Maximum Lockout Time After a Login Failure

Command	aaa local authentication lockout-time lockout-time
Parameter Description	<i>lockout-time:</i> Indicates the time during which a user is locked after entering wrong passwords up to the specified times. The value ranges from 1 to 2,147,483,647, in the unit of minutes.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum time during which a user is locked after entering wrong passwords up to the specified times.

Configuration Example

Configuring AAA Login Authentication

Configure a login authentication method list on the NAS containing **group** *radius* and **local** methods in order.

Scenario Figure 1-5	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.)</p> <p>Step 3: Configure an AAA authentication method list for login authentication users. (This example uses group <i>radius</i> and local in order.)</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authentication method is used.</p>
NAS	<pre>Nodexon#configure terminal Nodexon(config)#username user password pass Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key Nodexon Nodexon(config)#aaa authentication login list1 group radius local Nodexon(config)#line vty 0 20 Nodexon(config-line)#login authentication list1 Nodexon(config-line)#exit</pre>
Verification	<p>Run the show aaa method-list command on the NAS to display the configuration.</p>
NAS	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication login list1 group radius local Accounting method-list:</pre>

	Authorization method-list:
	Assume that a user remotely logs in to the NAS through Telnet. The user is prompted to enter the username and password on the CLI. The user must enter the correct username and password to access the NAS.
User	User Access Verification Username:user Password:pass

📌 **Configuring AAA Enable Authentication**

Configure an Enable authentication method list on the NAS containing **group radius**, **local**, and then **enable** methods in order.

Scenario Figure 1-6	<pre> graph LR User[User] --- Gi01[Gi 0/1] --- NAS[NAS] NAS --- Gi02[Gi 0/2] --- Server[Server] Server --- IP[10.1.1.1] </pre>
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. Configure Enable authentication passwords on the NAS if you use Enable password authentication.</p> <p>Step 3: Configure an AAA authentication method list for Enable authentication users.</p> <p>i You can define only one Enable authentication method list globally. You do not need to define the list name but just default it. After that, it will be applied automatically.</p>
NAS	<pre> Nodexon#configure terminal Nodexon(config)#username user privilege 15 password pass Nodexon(config)#enable secret w Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key Nodexon Nodexon(config)#aaa authentication enable default group radius local enable </pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre> Nodexon#show aaa method-list </pre>

	<pre>Authentication method-list: aaa authentication enable default group radius local enable Accounting method-list: Authorization method-list:</pre>
	<p>The CLI displays an authentication prompt when the user level is updated to level 15. The user must enter the correct username and password to access the NAS.</p>
<p>NAS</p>	<pre>Nodexon>enable Username:user Password:pass Nodexon#</pre>

📌 **Configuring AAA 802.1X Authentication**

Configure an 802.1X authentication method list on the NAS containing **group radius**, and then **local** methods in order.

<p>Scenario Figure 1-7</p>	 <pre> graph LR User[User] --- Gi01[Gi 0/1] --- NAS[NAS] NAS --- Gi02[Gi 0/2] --- Server[Server] subgraph Server_IP [10.1.1.1] Server end </pre>
<p>Configuration Steps</p>	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS server in advance if group-server authentication needs to be implemented. Configure the local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.) Currently, 802.1X authentication does not support TACACS+.</p> <p>Step 3: Configure an AAA authentication method list for 802.1X authentication users. (This example uses group radius and local in order.)</p> <p>Step 4: Apply the AAA authentication method list. Skip this step if the default authentication method is used.</p> <p>Step 5: Enable 802.1X authentication on an interface.</p>
<p>NAS</p>	<pre>Nodexon#configure terminal Nodexon(config)#username user1 password pass1 Nodexon(config)#username user2 password pass2 Nodexon(config)#aaa new-model</pre>

	<pre>Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key Nodexon Nodexon(config)#aaa authentication dot1x default group radius local Nodexon(config)#interface gigabitEthernet 0/1 Nodexon(config-if-gigabitEthernet 0/1)#dot1x port-control auto Nodexon(config-if-gigabitEthernet 0/1)#exit</pre>
Verification	Run the show aaa method-list command on the NAS to display the configuration.
NAS	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication dot1x default group radius local Accounting method-list: Authorization method-list:</pre>

Common Errors

- No RADIUS server or TACACS+ server is configured.
- Usernames and passwords are not configured in the local database.

1.4.2 Configuring AAA Authorization

Configuration Effect

- Determine what services or permissions authenticated users can enjoy.

Notes

- EXEC authorization is often used with login authentication, which can be implemented on the same line. Authorization and authentication can be performed using different methods and servers. Therefore, the results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot enter the CLI.
- The authorization methods in an authorization scheme are executed in accordance with the method configuration sequence. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried.
- Command authorization is supported only by TACACS+.

- Console authorization: The NXOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Defining a Method List of EXEC Authorization

- Run the **aaa authorization exec** command to configure a method list of EXEC authorization.
- This configuration is mandatory if you need to configure an EXEC authorization method list (including the configuration of the default method list).
- By default, no EXEC authorization method list is configured.

i The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)

↳ Defining a Method List of Command Authorization

- Run the **aaa authorization commands** command to configure a method list of command authorization.
- This configuration is mandatory if you need to configure a command authorization method list (including the configuration of the default method list).
- By default, no command authorization method list is configured.

↳ Configuring a Method List of Network Authorization

- Run the **aaa authorization network** command to configure a method list of network authorization.
- This configuration is mandatory if you need to configure a network authorization method list (including the configuration of the default method list).
- By default, no authorization method is configured.

↳ Applying EXEC Authorization Methods to a Specified VTY Line

- Run the **authorization exec** command in line configuration mode to apply EXEC authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

↳ Applying Command Authorization Methods to a Specified VTY Line

- Run the **authorization commands** command in line configuration mode to apply command authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

▾ Enabling Authorization for Commands in Configuration Modes

- Run the **aaa authorization config-commands** command to enable authorization for commands in configuration modes.
- By default, authorization is disabled for commands in configuration modes.

▾ Enabling Authorization for the Console to Run Commands

- Run the **aaa authorization console** command to enable authorization for console users to run commands.
- By default, authorization is disabled for the Console to run commands.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

▾ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

▾ Defining a Method List of EXEC Authorization

Command	aaa authorization exec { default list-name } method1 [method2...]
Parameter	default: With this parameter used, the configured method list will be defaulted.
Description	<p><i>list-name:</i> Indicates the name of an EXEC authorization method list in characters.</p> <p><i>method:</i> Specifies authentication methods from local, none, and group. A method list contains up to four methods.</p> <p>local: Indicates that the local user database is used for EXEC authorization.</p> <p>none: Indicates that EXEC authorization is not performed.</p> <p>group: Indicates that a server group is used for EXEC authorization. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode

Usage Guide	<p>The NXOS supports authorization of the users who log in to the CLI of the NAS to assign the users CLI operation permission levels (0 to 15). Currently, EXEC authorization is performed only on the users who have passed login authentication. If a user fails in EXEC authorization, the user cannot enter the CLI.</p> <p>After you configure EXEC authorization methods, apply the methods to the VTY lines that require EXEC authorization; otherwise, the methods will not take effect.</p>
--------------------	--

↘ Defining a Method List of Command Authorization

Command	aaa authorization commands <i>level</i> { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a command authorization method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that command authorization is not performed.</p> <p>group: Indicates that a server group is used for command authorization. Currently, the TACACS+ server group is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The NXOS supports authorization of the commands executable by users. When a user enters a command, AAA sends the command to the authentication server. If the authentication server permits the execution, the command is executed. If the authentication server forbids the execution, the command is not executed and a message is displayed showing that the execution is rejected.</p> <p>When you configure command authorization, specify the command level, which is used as the default level. (For example, if a command above Level 14 is visible to users, the default level of the command is 14.)</p> <p>After you configure command authorization methods, apply the methods to the VTY lines that require command authorization; otherwise, the methods will not take effect.</p>

↘ Configuring a Method List of Network Authorization

Command	aaa authorization network { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of a network authorization method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that authentication is not performed.</p> <p>group: Indicates that a server group is used for network authorization. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The NXOS supports authorization of network-related service requests such as PPP and SLIP requests. After authorization is configured, all authenticated users or interfaces are authorized automatically. You can configure three different authorization methods. The next authorization method is executed only when the current method does not receive response. If authorization fails using a method, the next method will be not tried.</p>

	RADIUS or TACACS+ servers return a series of AV pairs to authorize authenticated users. Network authorization is based on authentication. Only authenticated users can perform network authorization.
--	---

↘ **Enabling Authorization for Commands in Configuration Modes (Including the Global Configuration Mode and Sub-Modes)**

Command	aaa authorization config-commands
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If you need to enable authorization for commands only in non-configuration modes (for example, privileged EXEC mode), disable authorization in configuration modes by using the no form of this command. Then users can run commands in configuration mode and sub-modes without authorization.

↘ **Enabling Authorization for the Console to Run Commands**

Command	aaa authorization console
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The NXOS can differentiate between the users who log in through the Console and the users who log in through other types of clients. You can enable or disable command authorization for the users who log in through the Console. If command authorization is disabled for these users, the command authorization method list applied to the Console line no longer takes effect.

Configuration Example

↘ **Configuring AAA EXEC Authorization**

Configure login authentication and EXEC authorization for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC authorization is performed on a RADIUS server. If the RADIUS server does not respond, users are redirected to the local authorization.

Scenario Figure 1-8	<pre> graph LR User[User] --- Gi 0/1 NAS[NAS] NAS --- Gi 0/2 Server[Server] subgraph Server_IP [10.1.1.1] Server end </pre>
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p>

	<p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.</p> <p>EXEC authorization is often used with login authentication, which can be implemented on the same line.</p>
NAS	<pre>Nodexon#configure terminal Nodexon(config)#username user password pass Nodexon(config)#username user privilege 6 Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key test Nodexon(config)#aaa authentication login list1 group local Nodexon(config)#aaa authorization exec list2 group radius local Nodexon(config)#line vty 0 4 Nodexon(config-line)#login authentication list1 Nodexon(config-line)# authorization exec list2 Nodexon(config-line)#exit</pre>
Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication login list1 group local Accounting method-list: Authorization method-list: aaa authorization exec list2 group radius local</pre>
	<pre>Nodexon# show running-config aaa new-model ! aaa authorization exec list2 group local aaa authentication login list1 group radius local !</pre>

```

line vty 0 4

    authorization exec list2

    login authentication list1

!

End
    
```

➤ **Configuring AAA Command Authorization**

Provide command authorization for login users according to the following default authorization method: Authorize level-15 commands first by using a TACACS+ server. If the TACACS+ server does not respond, local authorization is performed. Authorization is applied to the users who log in through the Console and the users who log in through other types of clients.

<p>Scenario Figure 1-9</p>	
<p>Configuration Steps</p>	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.</p>
<p>NAS</p>	<pre> Nodexon#configure terminal Nodexon(config)#username user1 password pass1 Nodexon(config)#username user1 privilege 15 Nodexon(config)#aaa new-model Nodexon(config)#tacacs-server host 192.168.217.10 Nodexon(config)#tacacs-server key aaa </pre>

📌 **Configuring AAA Network Authorization**

<p>Scenario Figure 1-10</p>	
<p>Configuration Steps</p>	<p>Step 1: Enable AAA.</p> <p>Step 2: Configure a RADIUS or TACACS+ server in advance if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure the local user database information on the NAS.</p> <p>Step 3: Configure an AAA authorization method list according to different access modes and service types.</p> <p>Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.</p>
<p>NAS</p>	<pre>Nodexon#configure terminal Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key test Nodexon(config)#aaa authorization network default group radius none Nodexon(config)# end</pre>
<p>Verification</p>	<p>Run the show aaa method-list command on the NAS to display the configuration.</p>
<p>NAS</p>	<pre>Nodexon#show aaa method-list Authentication method-list: Accounting method-list:</pre>

```
Authorization method-list:  
aaa authorization network default group radius none
```

Common Errors

N/A

1.4.3 Configuring AAA Accounting

Configuration Effect

- Record the network resource usage of users.
- Record the user login and logout processes and the commands executed by users during device management.

Notes

About accounting methods:

- If an accounting scheme contains multiple accounting methods, these methods are executed according to the method configuration sequence. The next accounting method is executed only when the current method does not receive response. If accounting fails using a method, the next method will be not tried.
- After the default accounting method list is configured, it is applied to all VTY lines automatically. If a non-default accounting method list is applied to a line, it will replace the default one. If you apply an undefined method list to a line, the system will display a message indicating that accounting on this line is ineffective. Accounting will take effect only when a defined method list is applied.

EXEC accounting:

- EXEC accounting is performed only when login authentication on the NAS is completed. EXEC accounting is not performed if login authentication is not configured or the **none** method is used for authentication. If Start accounting is not performed for a user upon login, Stop accounting will not be performed when the user logs out.

Command accounting

- Only the TACACS+ protocol supports command accounting.

Configuration Steps

▾ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

▾ Defining a Method List of EXEC Accounting

- Run the **aaa accounting exec** command to configure a method list of EXEC accounting.

- This configuration is mandatory if you need to configure an EXEC accounting method list (including the configuration of the default method list).
- The default access permission level of EXEC users is the lowest. (Console users can connect to the NAS through the Console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.)
- By default, no EXEC accounting method list is configured.

▾ Defining a Method List of Command Accounting

- Run the **aaa accounting commands** command to configure a method list of command accounting.
- This configuration is mandatory if you need to configure a command accounting method list (including the configuration of the default method list).
- By default, no command accounting method list is configured. Only the TACACS+ protocol supports command accounting.

▾ Defining a Method List of Network Accounting

- Run the **aaa accounting network** command to configure a method list of network accounting.
- This configuration is mandatory if you need to configure a network accounting method list (including the configuration of the default method list).
- By default, no network accounting method list is configured.

▾ Applying EXEC Accounting Methods to a Specified VTY Line

- Run the **accounting exec** command in line configuration mode to apply EXEC accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

▾ Applying Command Accounting Methods to a Specified VTY Line

- Run the **accounting commands** command in line configuration mode to apply command accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

▾ Applying 802.1X Network Accounting Methods

- Run the **dot1x accounting network** command to configure 802.1X network accounting methods.
- This configuration is mandatory if you need to specify 802.1X network accounting methods.
- You do not need to run this command if you apply the default method list.

- By default, all VTY lines are associated with the default accounting method list.

↘ Enabling Accounting Update

- Optional.
- It is recommended that accounting update be configured for improved accounting accuracy.
- By default, accounting update is disabled.

↘ Configuring the Accounting Update Interval

- Optional.
- It is recommended that the accounting update interval not be configured unless otherwise specified.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA is not enabled.

↘ Defining a Method List of EXEC Accounting

Command	aaa accounting exec { default list-name } start-stop method1 [method2...]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name:</i> Indicates the name of an EXEC accounting method list in characters.</p> <p><i>method:</i> Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that EXEC accounting is not performed.</p> <p>group: Indicates that a server group is used for EXEC accounting. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The NXOS enables EXEC accounting only when login authentication is completed. EXEC accounting is not performed if login authentication is not performed or the none authentication method is used.</p> <p>After accounting is enabled, when a user logs in to the CLI of the NAS, the NAS sends a start-accounting message to the authentication server. When the user logs out, the NAS sends a stop-accounting message to the authentication server. If the NAS does not send a start-accounting message when the user logs in, the</p>

	<p>NAS will not send a stop-accounting message when the user logs out.</p> <p>After you configure EXEC accounting methods, apply the methods to the VTY lines that require EXEC accounting; otherwise, the methods will not take effect.</p>
--	--

↘ Defining a Method List of Command Accounting

Command	aaa accounting commands <i>level</i> { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	<p><i>level</i>: Indicates the command level for which accounting will be performed. The value ranges from 0 to 15.</p> <p>After a command of the configured level is executed, the accounting server records related information based on the received accounting packet.</p> <p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name</i>: Indicates the name of a command accounting method list in characters.</p> <p><i>method</i>: Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that command accounting is not performed.</p> <p>group: Indicates that a server group is used for command accounting. Currently, the TACACS+ server group is supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The NXOS enables command accounting only when login authentication is completed. Command accounting is not performed if login authentication is not performed or the none authentication method is used. After accounting is enabled, the NAS records information about the commands of the configured level that users run and sends the information to the authentication server.</p> <p>After you configure command accounting methods, apply the methods to the VTY lines that require command accounting; otherwise, the methods will not take effect.</p>

↘ Defining a Method List of Network Accounting

Command	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter Description	<p>default: With this parameter used, the configured method list will be defaulted.</p> <p><i>list-name</i>: Indicates the name of a network accounting method list in characters.</p> <p>start-stop: Indicates that a start-accounting message and a stop-accounting message are sent when a user accesses a network and when the user disconnects from the network respectively. The start-accounting message indicates that the user is allowed to access the network, regardless of whether accounting is successfully enabled.</p> <p><i>method</i>: Indicates authentication methods from none and group. A method list contains up to four methods.</p> <p>none: Indicates that network accounting is not performed.</p> <p>group: Indicates that a server group is used for network accounting. Currently, the RADIUS and TACACS+ server groups are supported.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The NXOS sends record attributes to the authentication server to perform accounting of user activities. The start-stop keyword is used to configure user accounting options.</p>

↘ Enabling Accounting Update

Command	aaa accounting update
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to enable accounting update.

↘ Configuring the Accounting Update Interval

Command	aaa accounting update periodic <i>interval</i>
Parameter Description	<i>Interval</i> : Indicates the accounting update interval, in the unit of minutes. The shortest is 1 minute.
Command Mode	Global configuration mode
Usage Guide	Accounting update cannot be used if the AAA services are not enabled. After the AAA services are enabled, run this command to configure the accounting update interval.

Configuration Example

↘ Configuring AAA EXEC Accounting

Configure login authentication and EXEC accounting for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC accounting is performed on a RADIUS server.

Scenario Figure 1-11	 <p>The diagram illustrates a network topology for AAA EXEC accounting. On the left, a laptop labeled 'User' is connected to a Network Access Server (NAS) device via interface GI 0/1. The NAS device is then connected to a Server via interface GI 0/2. The Server's IP address is shown as 10.1.1.1.</p>
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance.</p> <p>Step 2: Configure an AAA accounting method list according to different access modes and service types.</p> <p>Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.</p>
NAS	<pre>Nodexon#configure terminal Nodexon(config)#username user password pass Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key test</pre>

	<pre>Nodexon(config)#aaa authentication login list1 group local Nodexon(config)#aaa accounting exec list3 start-stop group radius Nodexon(config)#line vty 0 4 Nodexon(config-line)#login authentication list1 Nodexon(config-line)# accounting exec list3 Nodexon(config-line)#exit</pre>
Verification	Run the show run and show aaa method-list commands on the NAS to display the configuration.
NAS	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication login list1 group local Accounting method-list: aaa accounting exec list3 start-stop group radius Authorization method-list:</pre>
	<pre>Nodexon# show running-config aaa new-model ! aaa accounting exec list3 start-stop group radius aaa authentication login list1 group local ! username user password pass ! radius-server host 10.1.1.1 radius-server key 7 093b100133 ! line con 0 line vty 0 4 accounting exec list3 login authentication list1</pre>

```
!
End
```

📌 **Configuring AAA Command Accounting**

Configure command accounting for login users according to the default accounting method. Login authentication is performed in local mode, and command accounting is performed on a TACACS+ server.

<p>Scenario Figure 1-12</p>	
<p>Configuration Steps</p>	<p>Step 1: Enable AAA.</p> <p>If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance.</p> <p>Step 2: Configure an AAA accounting method list according to different access modes and service types.</p> <p>Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.</p>
<p>NAS</p>	<pre>Nodexon#configure terminal Nodexon(config)#username user1 password pass1 Nodexon(config)#username user1 privilege 15 Nodexon(config)#aaa new-model Nodexon(config)#tacacs-server host 192.168.217.10 Nodexon(config)#tacacs-server key aaa Nodexon(config)#aaa authentication login default local Nodexon(config)#aaa accounting commands 15 default start-stop group tacacs+</pre>
<p>Verification</p>	<p>Run the show aaa method-list command on the NAS to display the configuration.</p>
<p>NAS</p>	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication login default local Accounting method-list: aaa accounting commands 15 default start-stop group tacacs+</pre>

	Authorization method-list:
	<pre>Nodexon#show run ! aaa new-model ! aaa authorization config-commands aaa accounting commands 15 default start-stop group tacacs+ aaa authentication login default local ! ! nfpp ! vlan 1 ! username user1 password 0 pass1 username user1 privilege 15 no service password-encryption ! tacacs-server host 192.168.217.10 tacacs-server key aaa ! line con 0 line vty 0 4 ! ! end</pre>

📌 Configuring AAA Network Accounting

Configure a network accounting method list for 802.1X STAs, and configure a RADIUS remote server for authentication and accounting.

Scenario Figure 1-13	
Configuration Steps	<p>Step 1: Enable AAA.</p> <p>Step 2: If remote server-group accounting needs to be implemented, configure a RADIUS server in advance.</p> <p>Step 3: Configure an AAA accounting method list according to different access modes and service types.</p> <p>Step 4: Apply the configured AAA accounting method list. Skip this step if the default accounting method is used.</p> <hr/> <p> Accounting is performed only when 802.1X authentication is completed.</p>
NAS	<pre>Nodexon#configure terminal Nodexon(config)#username user password pass Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key test Nodexon(config)#aaa authentication dot1x autlx group radius local Nodexon(config)#aaa accounting network acclx start-stop group radius Nodexon(config)#dot1x authentication autlx Nodexon(config)#dot1x accounting acclx Nodexon(config)#interface gigabitEthernet 0/1 Nodexon(config-if-GigabitEthernet 0/1)#dot1 port-control auto Nodexon(config-if-GigabitEthernet 0/1)#exit</pre>
Verification	<p>Run the show aaa method-list command on the NAS to display the configuration.</p>
NAS	<pre>Nodexon#show aaa method-list Authentication method-list: aaa authentication dot1x autlx group radius local Accounting method-list: aaa accounting network acclx start-stop group radius Authorization method-list:</pre>

Common Errors

N/A

1.4.4 Configuring an AAA Server Group

Configuration Effect

- Create a user-defined server group and add one or more servers to the group.
- When you configure authentication, authorization, and accounting method lists, name the methods after the server group name so that the servers in the group are used to handle authentication, authorization, and accounting requests.
- Use self-defined server groups to separate authentication, authorization, and accounting.

Notes

In a user-defined server group, you can specify and apply only the servers in the default server group.

Configuration Steps

↳ Creating a User-Defined AAA Server Group

- Mandatory.
- Assign a meaningful name to the user-defined server group. Do not use the predefined **radius** and **tacacs+** keywords in naming.

↳ Adding an AAA Server Group Member

- Mandatory.
- Run the **server** command to add AAA server group members.
- By default, a user-defined server group does not have servers.

↳ Configuring the VRF Attribute of an AAA Server Group

- Optional.
- Run the **ip vrf forwarding** command to configure the VRF attribute of an AAA server group.
- By default, the AAA server group belongs to the global VRF table.

Verification

Run the **show aaa group** command to verify the configuration.

Related Commands

↳ Creating a User-Defined AAA Server Group

Command	aaa group server {radius tacacs+} name
Parameter	<i>name</i> : Indicates the name of the server group to be created. The name must not contain the radius and

Description	tacacs+ keywords because they are the names of the default RADIUS and TACACS+ server groups.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure an AAA server group. Currently, the RADIUS and TACACS+ server groups are supported.

Adding an AAA Server Group Member

Command	server <i>ip-addr</i> [auth-port <i>port1</i>] [acct-port <i>port2</i>]
Parameter Description	<i>ip-addr</i> : Indicates the IP address of a server. <i>port1</i> : Indicates the authentication port of a server. (This parameter is supported only by the RADIUS server group.) <i>port2</i> : Indicates the accounting port of a server. (This parameter is supported only by the RADIUS server group.)
Command Mode	Server group configuration mode
Usage Guide	When you add servers to a server group, the default ports are used if you do not specify ports.

Configuring the VRF Attribute of an AAA Server Group

Command	ip vrf forwarding <i>vrf_name</i>
Parameter Description	<i>vrf_name</i> : Indicates the name of a VRF table.
Command Mode	Server group configuration mode
Usage Guide	Use this command to assign a VRF table to the specified server group.

Configuration Example

Creating an AAA Server Group

Create RADIUS server groups named g1 and g2. The IP addresses of the servers in g1 are 10.1.1.1 and 10.1.1.2, and the IP addresses of the servers in g2 are 10.1.1.3 and 10.1.1.4.

<p>Prerequisites</p>	<ol style="list-style-type: none"> 1. The required interfaces, IP addresses, and VLANs have been configured on the network, network connections have been set up, and the routes from the NAS to servers are reachable. 2. Enable AAA.
<p>Configuration Steps</p>	<p>Step 1: Configure a server (which belongs to the default server group).</p> <p>Step 2: Create user-defined AAA server groups.</p> <p>Step 3: Add servers to the AAA server groups.</p>
<p>NAS</p>	<pre>Nodexon#configure terminal Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server host 10.1.1.2 Nodexon(config)#radius-server host 10.1.1.3 Nodexon(config)#radius-server host 10.1.1.4 Nodexon(config)#radius-server key secret Nodexon(config)#aaa group server radius g1 Nodexon(config-gs-radius)#server 10.1.1.1 Nodexon(config-gs-radius)#server 10.1.1.2 Nodexon(config-gs-radius)#exit Nodexon(config)#aaa group server radius g2</pre>
<p>Verification</p>	<p>Run the show aaa group and show run commands on the NAS to display the configuration.</p>
<p>NAS</p>	<pre>Nodexon#show aaa group Nodexon(config-gs-radius)#server 10.1.1.4 Type Reference Name ----- radius 1 radius tacacs+ 1 tacacs+ radius 1 g1 radius 1 g2</pre>
	<pre>Nodexon#show run</pre>

```
!  
radius-server host 10.1.1.1  
radius-server host 10.1.1.2  
radius-server host 10.1.1.3  
radius-server host 10.1.1.4  
radius-server key secret  
!  
aaa group server radius g1  
server 10.1.1.1  
server 10.1.1.2  
!  
aaa group server radius g2  
server 10.1.1.3  
server 10.1.1.4  
!  
!
```

Common Errors

- For RADIUS servers that use non-default authentication and accounting ports, when you run the **server** command to add servers, specify the authentication or accounting port.
- Only the RADIUS server group can be configured with the VRF attribute.

1.4.5 Configuring the Domain-Based AAA Service

Configuration Effect

Create AAA schemes for 802.1X users in different domains.

Notes

About referencing method lists in domains:

- The AAA method lists that you select in domain configuration mode should be defined in advance. If the method lists are not defined in advance, when you select them in domain configuration mode, the system prompts that the configurations do not exist.
- The names of the AAA method lists selected in domain configuration mode must be consistent with those of the method lists defined for the AAA service. If they are inconsistent, the AAA service cannot be properly provided to the users in the domain.

About the default domain:

- Default domain: After the domain-based AAA service is enabled, if a username does not carry domain information, the AAA service is provided to the user based on the default domain. If the domain information carried by the username is not configured in the system, the system determines that the user is unauthorized and will not provide the AAA service to the user. If the default domain is not configured initially, it must be created manually.
- When the domain-based AAA service is enabled, the default domain is not configured by default and needs to be created manually. The default domain name is **default**. It is used to provide the AAA service to the users whose usernames do not carry domain information. If the default domain is not configured, the AAA service is not available for the users whose usernames do not carry domain information.

About domain names:

- The domain names carried by usernames and those configured on the NAS are matched in the longest matching principle. For example, if two domains, **domain.com** and **domain.com.cn** are configured on a NAS and a user sends a request carrying **aaa@domain.com**, the NAS determines that the user belongs to **domain.com**, instead of **domain.com.cn**.
- If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the AAA service is not provided to the user.

Configuration Steps

↳ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

↳ Enabling the Domain-Based AAA Service

- Mandatory.
- Run the **aaa domain enable** command to enable the domain-based AAA service.
- By default, the domain-based AAA service is disabled.

↳ Creating a Domain and Entering Domain Configuration Mode

- Mandatory.
- Run the **aaa domain** command to create a domain or enter the configured domain.
- By default, no domain is configured.

↳ Associating the Domain with an 802.1X Authentication Method List

- Run the **authentication dot1x** command to associate the domain with an 802.1X authentication method list.
- This configuration is mandatory if you need to apply a specified 802.1X authentication method list to the domain.
- Currently, the domain-based AAA service is applicable only to 802.1X access.

↘ Associating the Domain with a Network Accounting Method List

- Run the **accounting network** command to associate the domain with a network accounting method.
- This configuration is mandatory if you need to apply a specified network accounting method list to the domain.
- If a domain is not associated with a network accounting method list, by default, the global default method list is used for accounting.

↘ Associating the Domain with a Network Authorization Method List

- Run the **authorization network** command to associate the domain with a network authorization method list.
- This configuration is mandatory if you need to apply a specified network authorization method list to the domain.
- If a domain is not associated with a network authorization method list, by default, the global default method list is used for authorization.

↘ Configuring the Domain Status

- Optional.
- When a domain is in Block state, the users in the domain cannot log in.
- By default, after a domain is created, its state is Active, indicating that all the users in the domain are allowed to request network services.

↘ Configuring Whether to Contain the Domain Name in Usernames

- Optional.
- By default, the usernames exchanged between the NAS and an authentication server carry domain information.

↘ Configuring the Maximum Number of Domain Users

- Optional.
- By default, the maximum number of access users allowed in a domain is not limited.

Verification

Run the **show aaa domain** command to verify the configuration.

Related Commands

↘ Enabling AAA

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To enable the AAA services, run this command. None of the rest of AAA commands can be effective if AAA

	is not enabled.
--	-----------------

↳ Enabling the Domain-Based AAA Service

Command	aaa domain enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the domain-based AAA service.

↳ Creating a Domain and Entering Domain Configuration Mode

Command	aaa domain { default domain-name }
Parameter	default: Uses this parameter to configure the default domain.
Description	<i>domain-name:</i> Indicates the name of the domain to be created.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure a domain to provide the domain-based AAA service. The default parameter specifies the default domain. If a username does not carry domain information, the NAS uses the method list associated with the default domain to provide the AAA service to the user. The <i>domain-name</i> parameter specifies the name of the domain to be created. If the domain name carried by a username matches the configured domain name, the NAS uses the method list associated with this domain to provide the AAA service to the user. The system supports a maximum of 32 domains.

↳ Associating the Domain with an 802.1X Authentication Method List

Command	authentication dot1x { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a 802.1X authentication method list.

↳ Associating the Domain with a Web Authentication Method List

Command	authentication web-auth { default list-name }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a Web authentication method list.

↳ Associating the Domain with a Network Accounting Method List

Command	accounting network { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a network accounting method list.

↘ Associating the Domain with a Network Authorization Method List

Command	authorization network { default <i>list-name</i> }
Parameter	default: Indicates that the default method list is used.
Description	<i>list-name:</i> Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	

↘ Configuring the Domain Status

Command	state { block active }
Parameter	block: Indicates that the configured domain is invalid.
Description	active: Indicates that the configured domain is valid.
Command Mode	Domain configuration mode
Usage Guide	Use this command to make the configured domain valid or invalid.

↘ Configuring Whether to Contain the Domain Name in Usernames

Command	username-format { without-domain with-domain }
Parameter	without-domain: Indicates to remove domain information from usernames.
Description	with-domain: Indicates to keep domain information in usernames.
Command Mode	Domain configuration mode
Usage Guide	Use this command in domain configuration mode to determine whether to include domain information in usernames when the NAS interacts with authentication servers in a specified domain.

↘ Configuring the Maximum Number of Domain Users

Command	access-limit <i>num</i>
Parameter	<i>num:</i> Indicates the maximum number of access users allowed in a domain. This limit is applicable only to 802.1X STAs.
Description	
Command Mode	Domain configuration mode
Usage Guide	Use this command to limit the number of access users in a domain.

Configuration Example

Configuring the Domain-Based AAA Services

Configure authentication and accounting through a RADIUS server to 802.1X users (username: *user@domain.com*) that access the NAS. The usernames that the NAS sends to the RADIUS server do not carry domain information, and the number of access users is not limited.

Scenario Figure 1-15	
Configuration Steps	<p>The following example shows how to configure RADIUS authentication and accounting, which requires the configuration of a RADIUS server in advance.</p> <p>Step 1: Enable AAA.</p> <p>Step 2: Define an AAA method list.</p> <p>Step 3: Enable the domain-based AAA service.</p> <p>Step 4: Create a domain.</p> <p>Step 5: Associate the domain with the AAA method list.</p> <p>Step 6: Configure the domain attribute.</p>
NAS	<pre>Nodexon#configure terminal Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 10.1.1.1 Nodexon(config)#radius-server key test Nodexon(config)#aaa authentication dot1x default group radius Nodexon(config)#aaa accounting network list3 start-stop group radius Nodexon(config)# aaa domain enable Nodexon(config)# aaa domain domain.com Nodexon(config-aaa-domain)# authentication dot1x default Nodexon(config-aaa-domain)# accounting network list3 Nodexon(config-aaa-domain)# username-format without-domain</pre>
Verification	<p>Run the show run and show aaa domain command on the NAS to display the configuration.</p>
NAS	<pre>Nodexon#show aaa domain domain.com =====Domain domain.com===== State: Active Username format: With-domain</pre>

	<pre>Access limit: No limit 802.1X Access statistic: 0 Selected method list: authentication dot1x default accounting network list3</pre>

Displays the AAA users.	show aaa user

Application	Description
Services for Access Users	
Forcing Users to Go Offline	The server forces an authenticated user to go offline.

2.2.1 Providing Authentication, Authorization, and Accounting Services for Access Users

Scenario

RADIUS is typically applied in the authentication, authorization, and accounting of access users. A network device serves as a RADIUS client and transmits user information to a RADIUS server. After completing processing, the RADIUS server returns the authentication acceptance/authentication rejection/accounting response information to the RADIUS client. The RADIUS client performs processing on the access user according to the response from the RADIUS server.

Figure 2-1 Typical RADIUS Networking Topology

Remarks	<p>PC 1 and PC 2 are connected to the RADIUS client as access users in wired mode, and initiate authentication and accounting requests.</p> <p>The RADIUS client is usually an access switch or aggregate switch.</p> <p>The RADIUS server can be a component built in the Windows 2000/2003, Server (IAS), or UNIX operating system or dedicated server software provided by vendors.</p>
----------------	--

Deployment

- Configure access device information on the RADIUS server, including the IP address and shared key of the access devices.
- Configure the AAA method list on the RADIUS client.
- Configure the RADIUS server information on the RADIUS client, including the IP address and shared key.
- Enable access control on the access port of the RADIUS client.
- Configure the network so that the RADIUS client communicates with the RADIUS server successfully.

2.2.2 Forcing Users to Go Offline

Scenario

The RADIUS server forces authenticated online users to go offline for the sake of management.

See Figure 2-1 for the networking topology.

Deployment

- Add the following deployment on the basis of 1.2.1 "Deployment".
- Enable the RADIUS dynamic authorization extension function on the RADIUS client.

2.3 Features

Basic Concepts

Client/Server Mode

- **Client:** A RADIUS client initiates RADIUS requests and usually runs on a device or NAS. It transmits user information to the RADIUS server, receives responses from the RADIUS server, and performs processing accordingly. The processing includes accepting user access, rejecting user access, or collecting more user information for the RADIUS server.
- **Server:** Multiple RADIUS clients map to one RADIUS server. The RADIUS server maintains the IP addresses and shared keys of all RADIUS clients as well as information on all authenticated users. It receives requests from a RADIUS client, conducts authentication, authorization, and accounting, and returns processing information to the RADIUS client.

Structure of RADIUS Packets

The following figure shows the structure of RADIUS packets.

- **Code:** Identifies the type of RADIUS packets, which occupies one byte. The following table lists the values and meanings.

Code	Packet Type	Code	Packet Type
1	Access-Request	4	Accounting-Request
2	Access-Accept	5	Accounting-Response
3	Access-Reject	11	Access-Challenge

- **Identifier:** Indicates the identifier for matching request packets and response packets, which occupies one byte. The identifier values of request packets and response packets of the same type are the same.

- **Length:** Identifies the length of a whole RADIUS packet, which includes **Code, Identifier, Length, Authenticator,** and **Attributes**. It occupies two bytes. Bytes that are beyond the **Length** field will be truncated. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.
- **Authenticator:** Verifies response packets of the RADIUS server by a RADIUS client, which occupies 16 bytes. This field is also used for encryption/decryption of user passwords.
- **Attributes:** Carries authentication, authorization, and accounting information, with the length unfixed. The **Attributes** field usually contains multiple attributes. Each attribute is represented in the Type, Length, Value (TLV) format. Type occupies one byte and indicates the attribute type. The following table lists common attributes of RADIUS authentication, authorization, and accounting. Length occupies one byte and indicates the attribute length, with the unit of bytes. Value indicates the attribute information.

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id
3	CHAP-Password	45	Acct-Authentic
4	NAS-IP-Address	46	Acct-Session-Time
5	NAS-Port	47	Acct-Input-Packets
6	Service-Type	48	Acct-Output-Packets
7	Framed-Protocol	49	Acct-Terminate-Cause
8	Framed-IP-Address	50	Acct-Multi-Session-Id
9	Framed-IP-Netmask	51	Acct-Link-Count
10	Framed-Routing	52	Acct-Input-Gigawords
11	Filter-ID	53	Acct-Output-Gigawords

13	Framed-Compression	60	CHAP-Challenge
14	Login-IP-Host	61	NAS-Port-Type
15	Login-Service	62	Port-Limit
16	Login-TCP-Port	63	Login-LAT-Port
18	Reply-Message	64	Tunnel-Type
19	Callback-Number	65	Tunnel-Medium-Type
20	Callback-ID	66	Tunnel-Client-Endpoint
22	Framed-Route	67	Tunnel-Server-Endpoint
23	Framed-IPX-Network	68	Acct-Tunnel-Connection
24	State	69	Tunnel-Password
25	Class	70	ARAP-Password
26	Vendor-Specific	71	ARAP-Features
27	Session-Timeout	72	ARAP-Zone-Access
28	Idle-Timeout	73	ARAP-Security
29	Termination-Action	74	ARAP-Security-Data
30	Called-Station-Id	75	Password-Retry

Attribute No.	Attribute Name	Attribute No.	Attribute Name
31	Calling-Station-Id	76	Prompt
32	NAS-Identifier	77	Connect-Info
33	Proxy-State	78	Configuration-Token
34	Login-LAT-Service	79	EAP-Message
35	Login-LAT-Node	80	Message-Authenticator
36	Login-LAT-Group	81	Tunnel-Private-Group-id
37	Framed-AppleTalk-Link	82	Tunnel-Assignment-id
38	Framed-AppleTalk-Network	83	Tunnel-Preference
39	Framed-AppleTalk-Zone	84	ARAP-Challenge-Response
40	Acct-Status-Type	85	Acct-Interim-Interval
41	Acct-Delay-Time	86	Acct-Tunnel-Packets-Lost
42	Acct-Input-Octets	87	NAS-Port-Id

Shared Key

A RADIUS client and a RADIUS server mutually confirm their identities by using a shared key during communication. The shared key cannot be transmitted over a network. In addition, user passwords are encrypted for transmission for the sake of security.

RADIUS Server Group

The RADIUS security protocol, also called RADIUS method, is configured in the form of a RADIUS server group. Each RADIUS method corresponds to one RADIUS server group and one or more RADIUS servers can be added to one RADIUS server group. For details about the RADIUS method, see the *Configuring AAA*. If you add multiple RADIUS servers to one RADIUS server group, when the communication between a device and the first RADIUS server in this group fails or the first RADIUS server becomes unreachable, the device automatically attempts to communicate with the next RADIUS server till the communication is successful or the communication with all the RADIUS servers fails.

RADIUS Attribute Type

- Standard attributes

The RFC standards specify the RADIUS attribute numbers and attribute content but do not specify the format of some attribute types. Therefore, the format of attribute contents needs to be configured to adapt to different RADIUS server requirements. Currently, the format of the RADIUS Calling-Station-ID attribute (attribute No.: 31) can be configured.

The RADIUS Calling-Station-ID attribute is used to identify user identities when a network device transmits request packets to the RADIUS server. The RADIUS Calling-Station-ID attribute is a string, which can adopt multiple formats. It needs to uniquely identify a user. Therefore, it is often set to the MAC address of a user. For example, when IEEE 802.1X authentication is used, the Calling-Station-ID attribute is set to the MAC address of the device where the IEEE 802.1X client is installed. The following table describes the format of MAC addresses.

Format	Description
ietf	Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC
Normal	Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac
Unformatted	Indicates the format without separators. This format is used by default. Example: 00d0f83322ac

- Private attributes

RADIUS is an extensible protocol. According to RFC2865, the Vendor-Specific attribute (attribute No.: 26) is used by device vendors to extend the RADIUS protocol to implement private functions or functions that are not defined in the standard RADIUS protocol. Table 1-3 lists private attributes supported by Nodexon products. The **TYPE** column indicates the default configuration of private attributes of Nodexon products and the **Extended TYPE** column indicates the default configuration of private attributes of other non-Nodexon products.

ID	Function	TYPE	Extended TYPE
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	vlan-id	4	4
5	last-supPLICANT-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13
14	file-name-3	14	14
15	file-name-4	15	15
16	max-up-rate	16	16
17	current-supPLICANT-version	17	17
18	flux-max-high32	18	18
19	flux-max-low32	19	19

21	dailup-avoid	21	21
22	ip-privilege	22	22
23	login-privilege	42	42

ID	Function	TYPE	Extended TYPE
26	ipv6-multicast-address	79	79
27	ipv4-multicast-address	87	87
62	sdg-type	62	62
85	sdg-zone-name	85	85
103	sdg-group-name	103	103

Overview

Feature	Description
RADIUS Authentication, Authorization, and Accounting	Conducts identity authentication and accounting on access users, safeguards network security, and facilitates management for network administrators.
Source Address of RADIUS Packets	Specifies the source IP address used by a RADIUS client to transmit packets to a RADIUS server.
RADIUS Timeout Retransmission	Specifies the packet retransmission parameter for a RADIUS client when a RADIUS server does not respond to packets transmitted from the RADIUS client within a period of time.
RADIUS Server Accessibility Detection	Enables a RADIUS client to actively detect whether a RADIUS server is reachable and maintain the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.
RADIUS Forced Offline	Enables a RADIUS server to actively force authenticated users to go offline.

2.3.1 RADIUS Authentication, Authorization, and Accounting

Conduct identity authentication and accounting on access users, safeguard network security, and facilitate management for network administrators.

Working Principle

Figure 2-2

The RADIUS authentication and authorization process is described as follows:

1. A user enters the user name and password and transmits them to the RADIUS client.
2. After receiving the user name and password, the RADIUS client transmits an authentication request packet to the RADIUS server. The password is encrypted for transmission. For the encryption method, see RFC2865.
3. The RADIUS server accepts or rejects the authentication request according to the user name and password. When accepting the authentication request, the RADIUS server also issues authorization information apart from the authentication acceptance information. The authorization information varies with the type of access users.

The RADIUS accounting process is described as follows:

1. If the RADIUS server returns authentication acceptance information in Step (3), the RADIUS client sends an accounting start request packet to the RADIUS server immediately.
2. The RADIUS server returns the accounting start response packet, indicating accounting start.
3. The user stops accessing network resources and requests the RADIUS client to disconnect the network connection.
4. The RADIUS client transmits the accounting end request packet to the RADIUS server.
5. The RADIUS server returns the accounting end response packet, indicating accounting end.
6. The user is disconnected and cannot access network resources.

Related Configuration

↘ Configuring RADIUS Server Parameters

No RADIUS server is configured by default.

You can run the **radius-server host** command to configure a RADIUS server.

At least one RADIUS server must be configured so that RADIUS services run normally.

↘ Configuring the AAA Authentication Method List

No AAA authentication method list is configured by default.

You can run the **aaa authentication** command to configure a method list for different user types and select **group radius** when setting the authentication method.

The RADIUS authentication can be conducted only after the AAA authentication method list of relevant user types is configured.

↘ Configuring the AAA Authorization Method List

No AAA authorization method list is configured by default.

You can run the **aaa authorization** command to configure an authorization method list for different user types and select **group radius** when setting the authorization method.

The RADIUS authorization can be conducted only after the AAA authorization method list of relevant user types is configured.

↘ Configuring the AAA Accounting Method List

No AAA accounting method list is configured by default.

You can run the **aaa accounting** command to configure an accounting method list for different user types and select **group radius** when setting the accounting method.

The RADIUS accounting can be conducted only after the AAA accounting method list of relevant user types is configured.

2.3.2 Source Address of RADIUS Packets

Specify the source IP address used by a RADIUS client to transmit packets to a RADIUS server.

Working Principle

When configuring RADIUS, specify the source IP address to be used by a RADIUS client to transmit RADIUS packets to a RADIUS server, in an effort to reduce the workload of maintaining a large amount of NAS information on the RADIUS server.

Related Configuration

The global routing is used to determine the source address for transmitting RADIUS packets by default.

Run the **ip radius source-interface** command to specify the source interface for transmitting RADIUS packets. The device uses the first IP address of the specified interface as the source address of RADIUS packets.

2.3.3 RADIUS Timeout Retransmission

Working Principle

After a RADIUS client transmits a packet to a RADIUS server, a timer is started to detect the response of the RADIUS server. If the RADIUS server does not respond within a certain period of time, the RADIUS client retransmits the packet.

Related Configuration

↘ [Configuring the RADIUS Server Timeout Time](#)

The default timeout time is 5 seconds.

You can run the **radius-server timeout** command to configure the timeout time. The value ranges from 1 second to 1,000 seconds.

The response time of a RADIUS server is relevant to its performance and the network environment. Set an appropriate timeout time according to actual conditions.

↘ [Configuring the Retransmission Count](#)

The default retransmission count is 3.

You can run the **radius-server retransmit** command to configure the retransmission count. The value ranges from 1 to 100.

↘ [Configuring Whether to Retransmit Accounting Update Packets](#)

Accounting update packets are not retransmitted by default.

You can run the **radius-server account update retransmit** command to configure retransmission of accounting update packets for authenticated users.

2.3.4 RADIUS Server Accessibility Detection

Working Principle

A RADIUS client actively detects whether a RADIUS server is reachable and maintains the accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve the handling performance of RADIUS services.

Related Configuration

↘ [Configuring the Criteria for the Device to Judge That a RADIUS Server Is Unreachable](#)

The default criteria configured for judging that a RADIUS server is unreachable meet the two conditions simultaneously: 1. The device does not receive a correct response packet from the RADIUS security server within 60 seconds. 2. The device transmits the request packet to the same RADIUS security server for consecutive 10 times.

You can run the **radius-server dead-criteria** command to configure the criteria for the device to judge that the RADIUS security server is unreachable.

↘ [Configuring the Test User Name for Actively Detecting the RADIUS Security Server](#)

No test user name is specified for actively detecting the RADIUS security server by default.

You can run the `radius-server host x.x.x.xtestusername xxx` command to configure the test user name.

2.3.5 RADIUS Forced Offline

Working Principle

Figure 2-3 DM Message Exchange of the RADIUS Dynamic Authorization Extension Protocol

The preceding figure shows the exchange of DM messages between the RADIUS server and the device. The RADIUS server transmits the Disconnect-Request message to UDP Port 3799 of the device. After processing, the device returns the Disconnect-Response message that carries the processing result to the RADIUS server.

Related Configuration

N/A

2.4 Configuration

Configuration	Description and Command
RADIUS Basic Configuration	(Mandatory) It is used to configure RADIUS authentication, authorization, and accounting.
	<code>radius-server host</code> Configures the IP address of the remote RADIUS security server.
	<code>radius-server key</code> Configures the shared key for communication between the device and the RADIUS server.
	<code>radius-server retransmit</code> Configures the request transmission count, after which the device confirms that a RADIUS server is unreachable.
	<code>radius-server timeout</code> Configures the waiting time, after which the device retransmits a request.
	<code>radius-server account update retransmit</code> Configures retransmission of accounting update packets for authenticated users.
	<code>ip radius source-interface</code> Configures the source address of RADIUS packets.
Configuring the RADIUS Attribute Type	(Optional) It is used to define attribute processing adopted when the device encapsulates and parses RADIUS packets.

Configuration	Description and Command	
	radius-serverattribute31	Configures the MAC address format of RADIUS attribute No. 31 (Calling-Station-ID).
	radius-server attribute class	Configures the parsing mode of the RADIUS Class attribute.
	radius attribute	Configures the RADIUS private attribute type.
	radius set qos cos	Sets the private attribute port-priority issued by the server to the COS value of an interface. For COS-relevant concepts, see the <i>Configuring QoS</i> .
	radius support cui	Configures the device to support the CUI attribute.
	radius-server authentication attribute	Configures whether RADIUS authentication request packets carry a specified attribute.
	radius-server account attribute	Configures whether RADIUS accounting request packets carry a specified attribute.
	radius-server authentication vendor	Configures whether RADIUS authentication request packets carry the private attributes of other vendors.
	radius-server account vendor	Configures whether RADIUS accounting request packets carry the private attributes of other vendors.
Configuring RADIUS Accessibility Detection	 (Optional) It is used to detect whether a RADIUS server is reachable and maintain the accessibility of the RADIUS server.	
	radius-server dead-criteria	Configures the global criteria for judging that a RADIUS security server is unreachable.
	radius-server deadtime	Configures the duration for the device to stop transmitting request packets to an unreachable RADIUS server.
	radius-server host	Configures the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.

2.4.1 RADIUS Basic Configuration

Configuration Effect

- RADIUS authentication, authorization, and accounting can be conducted after RADIUS basic configuration is complete.

Notes

- Before configuring RADIUS on the device, ensure that the network communication of the RADIUS server is in good condition.
- When running the **ip radius source-interface** command to configure the source address of RADIUS packets, ensure that the device of the source IP address communicates with the RADIUS server successfully.
- When conducting RADIUS IPv6 authentication, ensure that the RADIUS server supports RADIUS IPv6 authentication.

Configuration Steps

▾ Configuring the Remote RADIUS Security Server

- Mandatory.
- Configure the IP address, authentication port, accounting port, and shared key of the RADIUS security server.

▾ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

- Optional.
- Configure a shared key in global configuration mode for servers without a shared key.

 The shared key on the device must be consistent with that on the RADIUS server.

▾ Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

- Optional.
- Configure the request transmission count, after which the device confirms that a RADIUS server is unreachable, according to the actual network environment.

▾ Configuring the Waiting Time, After which the Device Retransmits a Request

- Optional.
- Configure the waiting time, after which the device retransmits a request, according to the actual network environment.

 In an 802.1X authentication environment that uses the RADIUS security protocol, if a network device serves as the 802.1X authenticator and Nodexon SU is used as the 802.1X client software, it is recommended that **radius-server timeout** be set to 3 seconds (the default value is 5 seconds) and **radius-server retransmit** be set to 2 (the default value is 3) on the network device.

▾ Configuring Retransmission of Accounting Update Packets for Authenticated Users

- Optional.
- Determine whether to enable the function of retransmitting accounting update packets of authenticated users according to actual requirements.

▾ Configuring the Source Address of RADIUS Packets

- Optional.
- Configure the source address of RADIUS packets according to the actual network environment.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.

- Enable the device to interact with the RADIUS server. Conduct packet capture to confirm that the device communicates with the RADIUS server over the RADIUS protocol.

Related Commands

▾ Configuring the Remote RADIUS Security Server

Command	radius-server host [oob] { <i>ipv4-address</i> <i>ipv6-address</i> } [auth-port <i>port-number</i>] [acct-port <i>port-number</i>] [test username <i>name</i> [idle-time <i>time</i>] [ignore-auth-port] [ignore-acct-port]] [key [0 7] <i>text-string</i>]
Parameter Description	<p>oob: Indicates oob authentication, that is, the source interface for transmitting packets to the RADIUS server is an mgmt port.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address of the RADIUS security server.</p> <p><i>ipv6-address</i>: Indicates the IPv6 address of the RADIUS security server.</p> <p>auth-port <i>port-number</i>: Indicates the UDP port for RADIUS identity authentication. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct identity authentication.</p> <p>acct-port <i>port-number</i>: Indicates the UDP port for RADIUS accounting. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct accounting.</p> <p>test username <i>name</i>: Enables the function of actively detecting the RADIUS security server and specifies the user name used for active detection.</p> <p>idle-time <i>time</i>: Indicates the interval for the device to transmit test packets to a reachable RADIUS security server. The default value is 60 minutes. The value ranges from 1 minute to 1,440 minutes (24 hours).</p> <p>ignore-auth-port: Disables the function of detecting the authentication port of the RADIUS security server. It is enabled by default.</p> <p>ignore-acct-port: Disables the function of detecting the accounting port of the RADIUS security server. It is enabled by default.</p> <p>key [0 7] <i>text-string</i> : Configures the shared key of the server. The global shared key is used if it is not configured.</p>
Command Mode	Global configuration mode
Usage Guide	A RADIUS security server must be defined to implement the AAA security service by using RADIUS. You can run the radius-server host command to define one or more RADIUS security servers. If a RADIUS security server is not added to a RADIUS server group, the device uses the global routing table when transmitting RADIUS packets to the RADIUS server. Otherwise, the device uses the VRF routing table of the RADIUS server group.

▾ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

Command	radius-server key [0 7] <i>text-string</i>
Parameter Description	<p><i>text-string</i>: Indicates the text of the shared key.</p> <p>0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.</p>
Command	Global configuration mode

Mode	
Usage Guide	A shared key is the basis for correct communication between the device and the RADIUS security server. The same shared key must be configured on the device and RADIUS security server so that they can communicate with each other successfully.

↘ **Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable**

Command	radius-server retransmit <i>retries</i>
Parameter Description	<i>retries</i> : Indicates the RADIUS retransmission count. The value ranges from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	The prerequisite for AAA to use the next user authentication method is that the current security server used for authentication does not respond. The criteria for the device to judge that a security server does not respond are that the security server does not respond within the RADIUS packet retransmission duration of the specified retransmission count. There is an interval between consecutive two retransmissions.

↘ **Configuring the Waiting Time, After which the Device Retransmits a Request**

Command	radius-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Command Mode	Global configuration mode
Usage Guide	Use this command to adjust the packet retransmission timeout time.

↘ **Configuring Retransmission of Accounting Update Packets for Authenticated Users**

Command	radius-server account update retransmit
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure retransmission of accounting update packets for authenticated users. Accounting update packets are not retransmitted by default. The configuration does not affect users of other types.

Configuration Example

↘ **Using RADIUS Authentication, Authorization, and Accounting for Login Users**

<p>Scenario Figure 2-4</p>	 <p>The diagram illustrates a network setup for RADIUS authentication. On the left, a laptop is connected to a central device labeled 'Radius client'. This client is then connected to three separate 'Radius server' units. The IP addresses for these servers are listed as 192.168.5.22, 192.168.5.34, and 3000::100.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable AAA. ● Configure the RADIUS server information. ● Configure to use the RADIUS authentication, authorization, and accounting methods. ● Apply the configured authentication method on the interface.

Common Errors

- The key configured on the device is inconsistent with that configured on the server.
- No method list is configured.

2.4.2 Configuring the RADIUS Attribute Type

Configuration Effect

- Define the attribute processing adopted when the device encapsulates and parses RADIUS packets.

Notes

- Private attributes involved in "Configuring the RADIUS Attribute Type" refer to Nodexon private attributes.

Configuration Steps

- **Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)**

- Optional.
- Set the MAC address format of **Calling-Station-Id** to a type supported by the server.
- **Configuring the Parsing Mode of the RADIUS Class Attribute**
- Optional.
- Configure the parsing mode of the Class attribute according to the server type.
- **Configuring the RADIUS Private Attribute Type**
- Optional.
- If the server is a Nodexon application server, the RADIUS private attribute type needs to be configured.
- **Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface**
- Optional.
- Set the private attribute **port-priority** issued by the server to the COS value of an interface as required.
- **Configures the Device to Support the CUI Attribute**
- Optional.
- Configure whether the device supports the RADIUS CUI attribute as required.
- **Configuring the Mode of Parsing Private Attributes by the Device**
- Optional.
- Configure the index of a Nodexon private attribute parsed by the device as required.
- **Configuring Whether RADIUS Authentication Request Packets Carry a Specified Attribute**
- Optional.
- Configure whether to specify the attribute type for RADIUS authentication request packets as required.
- **Configuring Whether RADIUS Accounting Request Packets Carry a Specified Attribute**
- Optional.
- Configure whether to specify the attribute type for RADIUS accounting request packets as required.
- **Configuring Whether RADIUS Authentication Request Packets Carry the Private Attribute of a Specified Vendor**
- Optional.
- Configure whether RADIUS authentication request packets carry the private attribute of a specified vendor as required.
- **Configuring Whether RADIUS Accounting Request Packets Carry the Private Attribute of a Specified Vendor**
- Optional.
- Configure whether RADIUS accounting request packets carry the private attribute of a specified vendor as required.

↘ Configuring Whether RADIUS Server Parses the Private Attribute of Cisco, Huawei or Microsoft

- Optional.
- Configure whether RADIUS server parses the private attribute of Cisco, Huawei or Microsoft.

↘ Configuring the Nas-Port-Id Encapsulation Format for RADIUS Packets

- Optional.
- In either QINQ or non-QINQ scenarios, configure the nas-port-id encapsulation format for RADIUS packets. By default, the packets are encapsulated in the normal format.

Verification

- Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using RADIUS.
- Enable the device to interact with the RADIUS server. Conduct packet capture to display the MAC address format of Calling-Station-Id.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that Nodexon private attributes are correctly parsed by the device.
- Enable the device to interact with the RADIUS server. Display the debug information of the device to check that the CUI attribute is correctly parsed by the device.

Related Commands

↘ Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

Command	radius-server attribute 31 mac format {ietf normal unformatted }
Parameter Description	<p>ietf: Indicates the standard format specified in the IETF standard (RFC3580), which is separated by the separator (-). Example: 00-D0-F8-33-22-AC.</p> <p>normal: Indicates the common format that represents a MAC address (dotted hexadecimal format), which is separated by the separator (.). Example: 00d0.f833.22ac.</p> <p>unformatted: Indicates the format without separators. This format is used by default. Example: 00d0f83322ac.</p>
Command Mode	Global configuration mode
Usage Guide	Some RADIUS security servers (mainly used for 802.1X authentication) can identify only MAC addresses in the IETF format. In this case, set the MAC address format of Calling-Station-ID to IETF.

↘ Configuring the Parsing Mode of the RADIUS Class Attribute

Command	radius-server attribute class user-flow-control { format-16bytes format-32bytes }
Parameter Description	<p>user-flow-control: Parses the rate limit configuration from the class attribute.</p> <p>format-16bytes: Sets the format of the rate limit value to 16 bytes in the class attribute.</p> <p>format-32bytes: Sets the format of the rate limit value to 32 bytes in the class attribute.</p>

Command Mode	Global configuration mode
Usage Guide	Configure this command if the server needs to issue the rate limit value by using the Class attribute.

▾ Setting the Private Attribute port-priority Issued by the Server to the COS Value of an Interface

Command	radius set qos cos
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to use the issued QoS value as the CoS value. The QoS value is used as the DSCP value by default.

▾ Configures the Device to Support the CUI Attribute

Command	radius support cui
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to enable the RADIUS-compliant device to support the CUI attribute.

▾ Configuring Whether RADIUS Authentication Request Packets Carry a Specified Attribute

Command	radius-server authentication attribute <i>type</i> package radius-server authentication attribute <i>type</i> unpackage
Parameter Description	<i>type</i> : Indicates the RADIUS attribute type. The value ranges from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	Use this command to specify the attribute to be carried in authentication request packets.

▾ Configuring Whether RADIUS Accounting Request Packets Carry a Specified Attribute

Command	radius-server account attribute <i>type</i> package radius-server account attribute <i>type</i> unpackage
Parameter Description	<i>type</i> : Indicates the RADIUS attribute type. The value ranges from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	Use this command to specify the attribute to be carried in accounting request packets.

▾ Configuring Whether RADIUS Authentication Request Packets Carry the Private Attribute of a Specified Vendor

Command	radius-server authentication vendor <i>vendor_name</i> package
Parameter	<i>vendor_name</i> : Indicates the vendor name. It can be set to cmcc , microsoft , or cisco .
Description	
Command Mode	Global configuration mode
Usage Guide	Use this command to configure whether authentication request packets carry the private attribute of a specified vendor.

↘ **Configuring Whether RADIUS Accounting Request Packets Carry the Private Attribute of a Specified Vendor**

Command	radius-server account vendor <i>vendor_name</i> package
Parameter	<i>vendor_name</i> : Indicates the vendor name. It can be set to cmcc , Microsoft , or cisco .
Description	
Command Mode	Global configuration mode
Usage Guide	Use this command to configure whether accounting request packets carry the private attribute of a specified vendor.

Configuration Example

↘ **Configuring the RADIUS Attribute Type**

Scenario	One authentication device
Configuration Steps	<ul style="list-style-type: none"> ● Configure the MAC address format of RADIUS Calling-Station-Id. ● Configure the RADIUS private attribute type. ● Set the QoS value issued by the RADIUS server as the COS value of the interface. ● Configure the RADIUS function to support the CUI attribute. ● Configure the device to support private attributes of other vendors. ● Configure authentication requests not to carry the NAS-PORT-ID attribute. ● Configure accounting requests to carry the CMCC private attribute. ● Configure the RADIUS server not to parse Cisco's private attributes contained in packets. ● Configure application of the nas-port-id encapsulation format in a QINQ scenario.
	<pre>Nodexon(config)#radius-server attribute 31 mac format ietf Nodexon(config)#radius attribute 16 vendor-type 211 Nodexon(config)#radius set qos cos Nodexon(config)#radius support cui Nodexon(config)#radius-server authentication attribute 87 unpackage Nodexon(config)#radius-server account vendor cmcc package</pre>

Verification	Conduct packet capture or display debug information of the device to check whether the RADIUS standard attributes and private attributes are encapsulated/parsed correctly.
---------------------	---

2.4.3 Configuring RADIUS Accessibility Detection

Configuration Effect

The device maintains the accessibility status of each configured RADIUS server: reachable or unreachable. The device will not transmit authentication, authorization, and accounting requests of access users to an unreachable RADIUS server unless all the other servers in the same RADIUS server group as the unreachable server are all unreachable.

The device actively detects a specified RADIUS server. The active detection function is disabled by default. If the active detection function is enabled for a specified RADIUS server, the device will, according to the configuration, periodically transmits detection requests (authentication requests or accounting requests) to the RADIUS server. The transmission interval is as follows:

- For a reachable RADIUS server, the interval is the active detection interval of the reachable RADIUS server (the default value is 60 minutes).
- For an unreachable RADIUS server, the interval is always 1 minute.

Notes

All the following conditions need to be met before the active detection function is enabled for a specified RADIUS server:

- The test user name of the RADIUS server is configured on the device.
- At least one tested port (authentication port or accounting port) of the RADIUS server is configured on the device.

If the following two conditions are all met, it is deemed that a reachable RADIUS server becomes unreachable:

- After the previous correct response is received from the RADIUS server, the time set in **radius-server dead-criteria time seconds** has elapsed.
- After the previous correct response is received from the RADIUS server, the count that the device transmits requests to the RADIUS server but fails to receive correct responses (including retransmission) reaches the value set in **radius-server dead-criteria tries number**.

If any of the following conditions is met, it is deemed that an unreachable RADIUS server becomes reachable:

- The device receives correct responses from the RADIUS server.
- The duration that the RADIUS server is in the unreachable state exceeds the time set in **radius-server deadtime** and the active detection function is disabled for the RADIUS server.
- The authentication port or accounting port of the RADIUS server is updated on the device.

Configuration Steps

📄 Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable

- Mandatory.

- Configuring the global criteria for judging that a RADIUS security server is unreachable is a prerequisite for enabling the active detection function.
- **Configuring the IP Address of the Remote RADIUS Security Server, Authentication Port, Accounting Port, and Active Detection Parameters**
- Mandatory.
- Configuring active detection parameters of the RADIUS server is a prerequisite for enabling the active detection function.
- **Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server**
- Optional.
- The configured duration for the device to stop transmitting request packets to an unreachable RADIUS server takes effect only when the active detection function is disabled for the RADIUS server.

Verification

- Run the **show radius server** command to display the accessibility information of each RADIUS server.

Related Commands

➤ **Configuring the Global Criteria for Judging That a RADIUS Security Server Is Unreachable**

Command	radius-server dead-criteria { <i>time seconds</i> [<i>tries number</i>] <i>tries number</i> }
Parameter Description	<p>time seconds: Indicates the time condition parameter. If the device fails to receive a correct response packet from a RADIUS security server within the specified time, it is deemed that the RADIUS security server meets the inaccessibility duration condition. The value ranges from 1 second to 120 seconds.</p> <p>tries number: Indicates the consecutive request timeout count. If the timeout count of request packets transmitted by the device to the same RADIUS security server reaches the preset count, it is deemed that the RADIUS security server meets the consecutive timeout count condition of inaccessibility. The value ranges from 1 to 100.</p>
Command Mode	Global configuration mode
Usage Guide	If a RADIUS security server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS security server is unreachable. Users can use this command to adjust parameter values in the duration condition and consecutive request timeout count condition.

➤ **Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server**

Command	Radius-server deadtime <i>minutes</i>
Parameter Description	<i>minutes:</i> Indicates the duration for the device to stop transmitting requests to an unreachable RADIUS security server, with the unit of minutes. The value ranges from 1 minute to 1,440 minutes (24 hours).
Command	Global configuration mode

Mode	
Usage Guide	If the active detection function is enabled for a RADIUS security server on the device, the time parameter in radius-server deadtime does not take effect on the RADIUS server. If the active detection function is disabled for a RADIUS security server, the device automatically restores the RADIUS security server to the reachable state when the duration that the RADIUS security server is in the unreachable state exceeds the time specified in radius-server deadtime .

Configuration Example

Configuring Accessibility Detection on the RADIUS Server

Scenario Figure 2-5	<p style="text-align: center;">192.168.5.22</p> <p style="text-align: center;">Radius client Radius server</p>
Configuration Steps	<ul style="list-style-type: none"> Configure the global criteria for judging that a RADIUS security server is unreachable. Configure the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.
RADIUS Client	<pre>Nodexon(config)#radius-server dead-criteria time120 tries 5 Nodexon(config)# radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90</pre>
Verification	<p>Disconnect the network communication between the device and the server with the IP address of 192.168.5.22. Conduct RADIUS authentication through the device. After 120 seconds, run the show radius server command to check that the server state is dead.</p>
	<pre>Nodexon#show running-config ... radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90 radius-server dead-criteria time 120 tries 5 ...</pre>

2.5 Monitoring

Clearing

! Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
-------------	---------

Clears statistics of the RADIUS dynamic authorization extension function and restarts statistics.	clear radius dynamic-authorization-extension statistics
---	--

Displaying

Description	Command
Displays global parameters of the RADIUS server.	show radius parameter
Displays the configuration of the RADIUS server.	show radius server
Displays statistics relevant to the RADIUS dynamic authorization extension function.	show radius dynamic-authorization-extension statistics
Displays statistics relevant to RADIUS authentication.	show radius auth statistics
Displays statistics relevant to RADIUS accounting.	show radius acct statistics
Displays configuration of RADIUS server groups.	show radius group
Displays RADIUS standard attributes.	show radius attribute

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the RADIUS event.	debugradiusevent
Debugs RADIUS packet printing.	debugradiusdetail
Debugs the RADIUS dynamic authorization extension function.	debug radiusextension event
Debugs the RADIUS dynamic authorization extension packet printing.	debug radius extension detail

3 Configuring TACACS+

3.1 Overview

TACACS+ is a security protocol enhanced in functions based on the Terminal Access Controller Access Control System (TACACS) protocol. It is used to implement the authentication, authorization, and accounting (AAA) of multiple users.

Protocols and Standards

- RFC 1492 Terminal Access Controller Access Control System

3.2 Applications

Application	Description
Managing and Controlling Login of End Users	Password verification and authorization need to be conducted on end users.

3.2.1 Managing and Controlling Login of End Users

Scenario

TACACS+ is typically applied in the login management and control of end users. A network device serves as the TACACS+ client and sends a user name and password to the TACACS+ server for verification. The user is allowed to log in to the network device and perform operations after passing the verification and obtaining authorization. See the following figure.

Figure 3-1

Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B, C, and D are servers that process TACACS+ requests.
----------------	--

Deployment

- Start the TACACS+ server on Server B, Server C, and Server D, and configure information on the access device (Device A) so that the servers provide TACACS+-based AAA function for the access device. Enable the AAA function on Device A to start authentication for the user login.
- Enable the TACACS+ client function on Device A, add the IP addresses of the TACACS+ servers (Server B, Server C, and Server D) and the shared key so that Device A communicates with the TACACS+ servers over TACACS+ to implement the AAA function.

3.3 Features

Basic Concepts

Format of TACACS+ Packets

Figure 3-2

4	8	16	24	32 bit
Major	Minor	Packet type	Sequence no.	Flags
Session ID				
Length				

- Major Version: Indicates the major TACACS+ version number.
- Minor Version: Indicates the minor TACACS+ version number.
- Packet Type: Indicates the type of packets, with the options including:
 TAC_PLUS_AUTHEN: = 0x01 (authentication);
 TAC_PLUS_AUTHOR: = 0x02 (authorization);
 TAC_PLUS_ACCT: = 0x03 (accounting)
- Sequence Number: Indicates the sequence number of a data packet in the current session. The sequence number of the first TACACS+ data packet in a session must be 1 and the sequence number of subsequent each data packet increases by one. Therefore, the client sends data packets only with an odd sequence number and TACACS+ Daemon sends packets only with an even sequence number.
- Flags: Contains various bitmap format flags. One of the bits in the value specifies whether data packets need to be encrypted.
- Session ID: Indicates the ID of a TACACS+ session.
- Length: Indicates the body length of a TACACS+ data packet (excluding the header). Packets are encrypted for transmission on a network.

Overview

Feature	Description
TACACS+ Authentication, Authorization, and Accounting	Conducts authentication, authorization, and accounting on end users.

3.3.1 TACACS+ Authentication, Authorization, and Accounting

Working Principle

The following figure uses basic authentication, authorization, and accounting of user login to describe interaction of TACACS+ data packets.

Figure 3-3

The entire basic message interaction process includes three sections:

1. The authentication process is described as follows:
 - 1) A user requests to log in to a network device.
 - 2) After receiving the request, the TACACS+ client sends an authentication start packet to the TACACS+ server.
 - 3) The TACACS+ server returns an authentication response packet, requesting the user name.

- 4) The TACACS+ client requests the user to enter the user name.
 - 5) The user enters the login user name.
 - 6) After receiving the user name, the TACACS+ client sends an authentication continuation packet that carries the user name to the TACACS+ server.
 - 7) The TACACS+ server returns an authentication response packet, requesting the login password.
 - 8) The TACACS+ client requests the user to enter the login password.
 - 9) The user enters the login password.
 - 10) After receiving the login password, the TACACS+ client sends an authentication continuation packet that carries the login password to the TACACS+ server.
 - 11) The TACACS+ server returns an authentication response packet, prompting that the user passes authentication.
2. The user authorization starts after successful authentication:
- 1) The TACACS+ client sends an authorization request packet to the TACACS+ server.
 - 2) The TACACS+ server returns an authorization response packet, prompting that the user passes authorization.
 - 3) After receiving the authorization success packet, the TACACS+ client outputs the network device configuration screen for the user.
3. Accounting and audit need to be conducted on the login user after successful authorization:
- 1) The TACACS+ client sends an accounting start packet to the TACACS+ server.
 - 2) The TACACS+ server returns an accounting response packet, prompting that the accounting start packet has been received.
 - 3) The user logs out.
 - 4) The TACACS+ client sends an accounting end packet to the TACACS+ server.
 - 5) The TACACS+ server returns an accounting response packet, prompting that the accounting end packet has been received.

3.4 Configuration

Configuration	Description and Command	
Configuring TACACS+ Basic Functions	 (Mandatory) It is used to enable the TACACS+ security service.	
	tacacs-server host	Configures the TACACS+ server.
	tacacs-server key	Specifies the key shared by the server and network device.

	tacacs-server timeout	Configures the global waiting timeout time of the TACACS+ server for communication between a network device and the TACACS+ server.
Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+	 (Optional) It is used to separately process authentication, authorization, and accounting requests.	
	aaa group server tacacs+	Configures TACACS+ server groups and divides TACACS+ servers into different groups.
	server	Adds servers to TACACS+ server groups.

3.4.1 Configuring TACACS+ Basic Functions

Configuration Effect

- The TACACS+ basic functions are available after the configuration is complete. When configuring the AAA method list, specify the method of using TACACS+ to implement TACACS+ authentication, authorization, and accounting.
- When authentication, authorization, and accounting operations are performed, TACACS+ initiates the authentication, authorization, and accounting requests to configured TACACS+ servers according to the configured sequence. If response timeout occurs on a TACACS+ server, TACACS+ traverses the TACACS+ server list in sequence.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

↳ Enabling AAA

- Mandatory. The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Command	aaa new-model
Parameter	N/A
Description	
Defaults	The AAA function is disabled.
Command Mode	Global configuration mode
Usage Guide	The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Configuring the IP Address of the TACACS+ Server

- Mandatory. Otherwise, a device cannot communicate with the TACACS+ server to implement the AAA function.

Command	tacacs-server host [oob] { <i>ipv4-address</i> <i>ipv6-address</i> } [port <i>integer</i>] [timeout <i>integer</i>] [key [0 7] <i>text-string</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the TACACS+ server.</p> <p><i>ipv6-address</i>: Indicates the IPv6 address of the TACACS+ server.</p> <p>oob: Uses an MGMT port as the source interface for communicating with the TACACS+ server. A non-MGMT port is used for communication by default.</p> <p>port <i>integer</i>: Indicates the TCP port used for TACACS+ communication. The default TCP port is 49.</p> <p>timeout <i>integer</i>: Indicates the timeout time of the communication with the TACACS+ server. The global timeout time is used by default.</p> <p>key [0 7] <i>text-string</i>: Indicates the shared key of the server. The global key is used if it is not configured. An encryption type can be specified for the configured key. The value 0 indicates no encryption and 7 indicates simple encryption. The default value is 0.</p>
Defaults	No TACACS+ server is configured.
Command Mode	Global configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. You can specify the shared key of the server when configuring the IP address of the server. If no shared key is specified, the global key configured using the tacacs-server key command is used as the shared key of the server. The shared key must be completely the same as that configured on the server. 2. You can specify the communication port of the server when configuring the IP address. 3. You can specify the communication timeout time of the server when configuring the IP address.

Configuring the Shared Key of the TACACS+ Server

- Optional.
- If no global communication protocol is configured using this command, set **key** to specify the shared key of the server when running the **tacacs-server host** command to add server information. Otherwise, a device cannot communicate with the TACACS+ server.
- If no shared key is specified by using **key** when you run the **tacacs-server host** command to add server information, the global key is used.

Command	tacacs-server [key [0 7] <i>text-string</i>]
Parameter Description	<p><i>text-string</i>: Indicates the text of the shared key.</p> <p>0 7: Indicates the encryption type of the key. The value 0 indicates no encryption and 7 indicates simple encryption.</p>
Defaults	No shared key is configured for any TACACS+ server.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure a global shared key for servers. To specify a different key for each

	server, set key when running the tacacs-server host command.
--	--

➤ **Configuring the Timeout Time of the TACACS+ Server**

- Optional.
- You can set the timeout time to a large value when the link between the device and the server is unstable.

Command	tacacs-server timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the timeout time, with the unit of seconds. The value ranges from 1 second to 1,000 seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the global server response timeout time. To set different timeout time for each server, set timeout when running the tacacs-server host command.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable the device to interact with the TACACS+ server and conduct packet capture to check the TACACS+ interaction process between the device and the TACACS+ server.
- View server logs to check whether the authentication, authorization, and accounting are normal.

Configuration Example

➤ **Using TACACS+ for Login Authentication**

Scenario Figure 3-4	<p>The diagram illustrates a network topology for TACACS+ authentication. On the left, a laptop icon represents the 'User'. A horizontal line connects the laptop to a central device labeled 'A', which is identified as the 'TACACS+ Client'. Another horizontal line connects device 'A' to a server rack icon labeled 'B', identified as the 'TACACS+ Server' with the IP address '192.168.5.22'.</p>
Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ requests.
Configuration Steps	<ul style="list-style-type: none"> ● Enable AAA. ● Configure the TACACS+ server information. ● Configure the method of using TACACS+ for authentication. ● Apply the configured authentication method on an interface.

A	<pre>Nodexon# configure terminal Nodexon(config)# aaa new-model Nodexon(config)# tacacs-server host 192.168.5.22 Nodexon(config)# tacacs-server key aaa Nodexon(config)# aaa authentication login test group tacacs+ Nodexon(config)# line vty 0 4 Nodexon(config-line)# login authentication test</pre>
Verification	Telnet to a device from a PC. The screen requesting the user name and password is displayed. Enter the correct user name and password to log in to the device. View the authentication log of the user on the TACACS+ server.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- No method list is configured.

3.4.2 Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+

Configuration Effect

- The authentication, authorization, and accounting in the security service are processed by different TACACS+ servers, which improves security and achieves load balancing to a certain extent.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

📌 Configuring TACACS+ Server Groups

- Mandatory. There is only one TACACS+ server group by default, which cannot implement separate processing of authentication, authorization, and accounting.
- Three TACACS+ server groups need to be configured for separately processing authentication, authorization, and accounting.

Command	aaa group server tacacs+ <i>group-name</i>
Parameter Description	<i>group-name</i> : Indicates the name of a group. A group name cannot be radius or tacacs+, which are the names of embedded groups.
Defaults	No TACACS+ server group is configured.
Command Mode	Global configuration mode
Usage Guide	Group TACACS+ servers so that authentication, authorization, and accounting are completed by different server groups.

✚ Adding Servers to TACACS+ Server Groups

- Mandatory. If no server is added to a server group, a device cannot communicate with TACACS+ servers.
- In server group configuration mode, add the servers that are configured using the **tacacs-server host** command.

Command	server { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter Description	<i>ipv4-address</i> : Indicates the IPv4 address of the TACACS+ server. <i>ipv6-address</i> : Indicates the IPv6 address of the TACACS+ server.
Defaults	No server is configured.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For the address of a server configured in a TACACS+ server group, the server must be configured using the tacacs-server host command in global configuration mode. If multiple servers are added to one server group, when one server does not respond, the device continues to send a TACACS+ request to another server in the server group.

✚ Configuring VRF of a TACACS+ Server Group

- Optional. Configure Virtual Routing and Forwarding (VRF) if a device needs to send TACACS+ packets through a specified address.
- In server group configuration mode, use a configured VRF name to specify the routing for the communication of servers in this group.

Command	ip vrf forwarding <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Indicates the VRF name.
Defaults	No VRF is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. For VRF configured in a TACACS+ server group, a valid name must be configured for VRF by using the vrf

definition command in global configuration mode.

➤ **Configuring oob of a TACACS+ Server Group**

- Optional. Configure oob if a device needs to send TACACS+ packets through a specified MGMT port.
- In server group configuration mode, specify routing for the communication of servers in the group.

Command	ip oob ip vrf forwarding <i>vrf-name</i>
Parameter Description	ip oob: Indicates the MGMT0 port. vrf-name: Indicates the VRF name.
Defaults	No oob is specified by default.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the aaa group server tacacs+ command to enter the TACACS+ server group configuration mode. If no MGMT port is specified, the MGMT0 port is used by default.

Verification

Configure the AAA method list that specifies to conduct authentication, authorization, and accounting on users by using TACACS+.

- Enable a device to interact with TACACS+ servers. Conduct packet capture, check that the authentication, authorization, and accounting packets are interacted with different servers, and check the source addresses in packets.

Configuration Example

➤ **Configuring Different TACACS+ Server Groups for Separately Processing Authentication, Authorization, and Accounting**

Scenario Figure 3-5	<p>The diagram illustrates a network setup for TACACS+ authentication. On the left, a laptop icon labeled 'User' is connected to a central server icon labeled 'A' and 'TACACS+ Client'. From server 'A', three lines connect to three separate server icons on the right, labeled 'B', 'C', and 'D', collectively titled 'TACACS+ Server'. Server B has the IP address 192.168.5.22, server C has 192.168.5.34, and server D has 192.168.5.44.</p>
Remarks	<ul style="list-style-type: none"> ● A is a client that initiates TACACS+ requests. ● B is a server that processes TACACS+ authentication requests.

	<ul style="list-style-type: none"> ● C is a server that processes TACACS+ authorization requests. ● D is a server that processes TACACS+ accounting requests.
Configuration Steps	<ul style="list-style-type: none"> ● Enable AAA. ● Configure the TACACS+ server information. ● Configure TACACS+ server groups. ● Add servers to TACACS+ server groups. ● Configure the method of using TACACS+ for authentication. ● Configure the method of using TACACS+ for authorization. ● Configure the method of using TACACS+ for accounting. ● Apply the configured authentication method on an interface. ● Apply the configured authorization method on an interface. ● Apply the configured accounting method on an interface.

4 Configuring 802.1X

4.1 Overview

IEEE 802.1X is a standard for port-based network access control that provides secure access service for local area networks (LANs).

In IEEE 802-compliant LANs, users connecting to the network access devices (NASs) can access network resources without authentication and authorization, bringing security risks to the network. IEEE 802.1X was proposed to resolve security problems of such LANs.

802.1X supports three security applications: authentication, authorization, and accounting, which are called AAA.

- Authentication: Checks whether to allow user access and restricts unauthorized users.
- Authorization: Grants specified services to users and controls permissions of authorized users.
- Accounting: Records network resource status of users to provide statistics for charges.

802.1X can be deployed in a network to realize user authentication, authorization and other functions.

Protocols and Standards

- IEEE 802.1X: Port-Based Network Access Control

4.2 Applications

Application	Description
Wired 802.1X Authentication	To ensure secure admission on the campus network, 802.1X authentication is deployed on access switches.

4.2.1 Wired 802.1X Authentication

Scenario

The campus network is deployed at the access, convergence, and core layers. 802.1X is deployed on access switches connected to dormitories to perform secure admission. Dormitory users must pass 802.1X authentication before accessing the campus network.

As shown in Figure 4-1:

- User ends must be installed with 802.1X clients (which can come with the operating system, or others like Nodexon Supplicant).
- Access switches support 802.1X.

- One or multiple Remote Authentication Dial-In User Service (RADIUS) servers perform authentication.

Figure 4-1

Remarks	The supplicant software installed on the user ends (or software coming with the operating system) performs 802.1X authentication. 802.1X authentication is deployed on access switches, convergence switches, or core switches. The RADIUS server runs the RADIUS server software to perform identity verification.
----------------	---

Deployment

- Enable 802.1X authentication on ports between access switches and users to make ports controllable. Only authenticated users on one port can access the network.
- Configure an AAA authentication method list so that 802.1X can adopt the appropriate method and authentication server.
- Configure RADIUS parameters to ensure proper communication between a switch and the RADIUS server. For details, see the *Configuring RDS*.
- If a Nodexon RADIUS server is used, configure SNMP parameters to allow the RADIUS server to manage devices, such as querying and setting.
- Configure the port between the access switch and the RADIUS server as an uncontrolled port to ensure proper communication between them.
- Create an account on the RADIUS server, register the IP address of an access switch, and configure RADIUS-related parameters. Only in this case, can the RADIUS server respond to the requests of the switch.

4.2.2 MAB Auto Authentication

Scenario

MAC address bypass (MAB) auto authentication indicates that MAB authentication is performed together with Web authentication. In the original wireless Web authentication scenario, it is complained that the ease-to-use performance of Web authentication is poor. During each Web authentication, a user needs to associate the STA with an SSID, open the browser, and enter the user name and password. In addition, if the STA drops out of the network, the STA cannot automatically access the network again. To ensure that all Web authenticated STAs are always online and access the network imperceptibly, MAB auto authentication is proposed. After a STA passes Web authentication, the STA can access the network again imperceptibly without Web authentication.

As shown in Figure 4-1:

- Only the browser is mandatory on the client.
- The AC supports Web authentication and MAB authentication.
- One or multiple RADIUS servers provide authentication. In addition, the authentication server supports the authentication mode of using the MAC address as the user name and password.

Figure 4-2

Remarks	Wireless MAB authentication is triggered by a STA advertisement. When a STA is already online, MAB authentication will not be triggered again. If MAB authentication fails, it can be triggered again only after the STA
----------------	--

goes offline and reconnects to the network.

Deployment

- Enable Web authentication, DOT1X authentication, and MAB authentication on the interface of the AC. MAB authentication can be performed only after DOT1X authentication is enabled. (For details about MAB authentication, see section 4.4.5 "Configuring MAB Auto Authentication". For details about Web authentication, see the WEB-AUTH-SCG document.)
- Configure an AAA authentication method list, so that a correct method and authentication server can be used for MAB/Web authentication. (For details about the AAA authentication method list configuration, see the AAA-SCG document.)
- Configure RADIUS parameters to ensure proper communication between the AC and the RADIUS server. In addition, configure the RADIUS server to support the authentication mode of using the MAC address as the user name and password. For details about the RADIUS configuration, see the corresponding configuration guide.
- If a Nodexon RADIUS server is used, configure SNMP parameters to allow the RADIUS server to perform operations such as querying and setting on the AP.
- Create an account on the RADIUS server, register the IP address of the AC, and configure RADIUS-related parameters. The RADIUS server can respond to the requests of the AP and AC only after the foregoing settings are completed.

4.3 Features

Basic Concepts

↘ User

In wired environment, 802.1X is a LAN-based protocol. It identifies users based on physical information but not accounts. In a LAN, a user is identified by the MAC address and VLAN ID (VID). Except them, all other information such as the account ID and IP address can be changed.

↘ RADIUS

RADIUS is a remote authentication protocol defined in RFC2865, which get wide practice. Using this protocol, the authentication server can remotely deploy and perform authentication. During 802.1X deployment, the authentication server is remotely deployed, and 802.1X authentication information between the NAS and the authentication server is transmitted through RADIUS.

↘ Timeout

During authentication, an NAS needs to communicate with the authentication client and server. If the authentication client or server times out, not responding within the time specified by 802.1X, authentication will fail. During deployment, ensure that the timeout specified by 802.1X is longer than that specified by RADIUS.

↘ MAB

MAC address bypass (MAB) authentication means that the MAC address is used as the user name and password for authentication. Since Nodexon Supplicant cannot be installed on some dumb ends such as network printers, use MAB to perform security control.

↳ EAP

802.1X uses Extensible Authentication Protocol (EAP) to carry authentication information. Defined in RFC3748, EAP provides a universal authentication framework, in which multiple authentication modes are embedded, including Message Digest Algorithm 5 (MD5), Challenge Handshake Authentication Protocol (CHAP), Password Authentication Protocol (PAP), and Transport Layer Security (TLS). Nodexon 802.1X authentication supports various modes including MD5, CHAP, PAP, PEAP-MSCHAP, and TLS.

↳ Authorization

Authorization means to bind specified services to authenticated users, such as IP address, VLAN, Access Control List (ACL), and Quality of Service (QoS).

↳ Accounting

i Accounting performs network audit on network usage duration and traffic for users, which facilitates network operation. Some RADIUS servers such as NX-SAM/NX-SMP servers need to check the online/offline status based on accounting maintenance, and management. packets. Therefore, accounting must be enabled on these RADIUS servers.

Overview

Feature	Description
Authentication	Provides secure admission for users. Only authenticated users can access the network.
Authorization	Grants network access rights to authenticated users, such as IP address binding and ACL binding
Accounting	Provides online record audit, such as online duration and traffic.

4.3.1 Authentication

Authentication aims to check whether users are authorized and prevent unauthorized users from accessing the network. Users must pass authentication to obtain the network access permission. They can access the network only after the authentication server verifies the account. Before user authentication succeeds, only EAPOL packets (Extensible Authentication Protocol over LAN, 802.1X packets) can be transmitted over the network for authentication.

Working Principle

802.1X authentication is very simple. After a user submits its account information, the NAS sends the account information to the remote RADIUS server for identity authentication. If the authentication succeeds, the user can access the network.

↳ Roles in Authentication

802.1X authentication involves three roles: supplicant, authenticator, and server. In real applications, their respective roles are client, network access server (NAS), and authentication server (mostly RADIUS server).

Figure 4-3

- Supplicant

The supplicant is the role of end users, usually a PC. It requests to access network services and replies to the request packets of the authenticator. The supplicant must run software compliant with the 802.1X standard. Except the typical 802.1X client support embedded in the operating system, Nodexon has launched a Nodexon Supplicant compliant with the 802.1X standard.

- Authenticator

The authenticator is usually an NAS such as a switch access hotspot. It controls the network connection of a client based on the client's authentication status. As a proxy between the client and the authentication server, the authenticator requests the user name from the client, verifies the authentication information from the authentication server, and forwards it to the client. Except as the 802.1X authenticator, the so-called NAS also acts as a RADIUS Client. It encapsulates the replies of the client into the RADIUS-format packets and forwards the packets to the RADIUS server. After receiving the information from the RADIUS server, it interprets the information and forwards it to the client.

The authenticator has two types of ports: controlled port and uncontrolled port. Users connected to controlled ports can access network resources only when authenticated. Users connected to uncontrolled ports can directly access network resources without authentication. We can connect users to controlled ports to control users. Uncontrolled ports are mainly used to connect the authentication server to ensure proper communication between the authentication server and the NAS.

- Authentication server

The authenticator server is usually an RADIUS server. It cooperates with the authenticator to provide authentication service for users. The authentication server saves the user names, passwords, and related authorization information. One server can provides authentication service for multiple authenticators to achieve centralized user management. The authentication server also manages accounting data received from authenticators. Nodexon RADIUS servers compliant with 802.1X standard

include Microsoft IAS/NPS, Free RADIUS Server, and Cisco ACS.

↘ Authentication Process and Packet Exchange

The supplicant exchanges information with the authenticator through EAPOL while exchanges information with the authentication server through RADIUS. EAPOL is encapsulated on the MAC layer, with the type number of 0x888E. IEEE

assigned a multicast MAC address 01-80-C2-00-00-03 for EAPOL to exchange packets during initial authentication. Nodexon Supplicant may also use 01-D0-F8-00-00-03 to for initial authentication packets.

Figure 4-4 shows the typical authentication process of a wired user.

Figure 4-4

This is a typical authentication process initiated by a user. In special cases, the NAS, may take place of the user to initiate an authentication request.

Authenticating User Status

802.1X determines whether a user on a port can access the network based on the authentication status of the port.

Nodexon products extend the 802.1X and realizes access control based on users (identify a wired user by the MAC address) by

default. Nodexon 802.1X can also be enabled in interface configuration mode. For details, see the chapter "Configuration."

All users on an uncontrolled port can access network resources, while users on a controlled port can access network resources only after authorized. When a user initiates authentication, its status remains Unauthorized and cannot access the network yet. After it passes authentication, its status changes to Authorized and can access network resources.

If the user connected to a controlled port does not support 802.1X, it will not respond to the NAS requesting the user name of the user. That means, the user remains Unauthorized and cannot access network resources.

In the case of 802.1X-enabled user and 802.1X-disabled NAS, if the user does not receive any responses after sending a specified number of EAPOL-Start packets, it regards the connected port uncontrolled and directly accesses network resources.

On 802.1X-enabled devices, all ports are uncontrolled by default. We can configure a port as controlled so that all users on this port have to be authorized.

If a user passes authentication (that is, the NAS receives a success packet from the RADIUS server), the user becomes Authorized and can freely access network resources. If the user fails in authentication, it remains Unauthorized and re-initiates authentication. If the communication between the NAS and the RADIUS server fails, the user remains Unauthorized and cannot access network resources.

When a user sends an EAPOL-LOGOFF packet, the user's status changes from Authorized to Unauthorized.

When a port of the NAS goes down, all users on this port will become Unauthorized.

When the NAS restarts, all users on it become Unauthorized.

▾ Deploying the Authentication Server

802.1X authentication uses the RADIUS server as the authentication server. Therefore, when 802.1X secure admission is deployed, the RADIUS server also needs to be deployed. Common RADIUS servers include Microsoft IAS/NPS, Cisco ACS, and NX-SAM/SMP. For details about the deployment procedure, see related software description.

▾ Configuring Authentication Parameters

To use 802.1X authentication, enable 802.1X authentication on the access port and configure AAA authentication method list and RADIUS server parameters. To ensure the accessibility between the NAS and RADIUS server, the 802.1X server timeout should be longer than the RADIUS server timeout.

▾ Supplicant

A user should start Nodexon Supplicant to enter the user name and initiate authentication. If the operating system brings an own authentication client and the network is available, a dialog box will be displayed, asking the user to enter the user name. Different clients may have different implementation processes and Graphical User Interfaces (GUIs). It is recommended to use Nodexon Supplicant as the authentication client. If other software is used, see related software description.

▾ Offline

If a user does not want to access the network, it can choose to go offline by multiple approaches, such as powering off the device, connecting the port to the network, and offline function provided by some supplicants.

4.3.2 Authorization

After a user passes authentication, the NAS restricts the accessible network resources of the user in multiple approaches, such as binding the IP address and the MAC address, and specifying the maximum online time or period, accessible VLANs, and bandwidth limit.

Working Principle

Authorization means to bind the permissions with the users. A user is identified based on the MAC address and VLAN ID, as mentioned before. Besides MAC-VID binding, some other information such as the IP address and VLAN ID are bound with a user to implement authorization.

▾ IP Authorization

802.1X does not support IP address identification. Nodexon 802.1X authentication extends 802.1X to support IP-MAC binding, which is called IP authorization. IP authorization supports four modes:

Supplicant authorization: The IP address is provided by Nodexon Supplicant.

RADIUS authorization: After successful authentication, the RADIUS server delivers the IP address to the NAS.

DHCP authorization: In such case, an authenticated user will initiate a DHCP request to obtain an IP address, and then bind the IP address with the MAC address of the client.

Mixed authorization: IP-MAC binding is configured for users in the following sequence: Supplicant authorization -> RADIUS authorization -> DHCP authorization. That is, the IP address provided by Nodexon Supplicant preferred, then the IP address provided by the RADIUS server, and finally the IP address provided by DHCP.

➤ ACL Authorization

After user authentication is complete, the authentication server delivers the ACL or ACE to users. The ACL must be configured on the authentication server before delivery while no extra configuration is required for ACE delivery. ACL authorization delivers the ACL based on RADIUS attributes such as standard attributes, Nodexon-proprietary attributes, and

Cisco-proprietary attributes. For details, see the software description related to the RADIUS server.

➤ Kickoff

Used with NX-SAM/SMP, Nodexon 802.1X server can kick off online users who will be disconnected with the network. This function applies to the environment where the maximum online period and real-time accounting check function are configured.

4.3.3 Accounting

Accounting allows the network operators to audit the network access or fees of accessed users, including the online time and traffic. Accounting is enabled on the NAS. The RADIUS server supports RFC2869-based accounting. When a user goes online, the NAS sends an accounting start packet to the RADIUS server which then starts accounting. When the user goes offline, the NAS sends an accounting end packet to the RADIUS server which then completes the accounting and generates a network fee accounting list. Different servers may perform accounting in different ways. Moreover, not all servers support accounting. Therefore, refer to the usage guide of the authentication server during actual deployment and accounting.

➤ Accounting Start

After a user passes authentication, the accounting-enabled switch sends the RADIUS server an accounting start packet carrying user accounting attributes such as user name and accounting ID. After receiving the packet, the RADIUS server starts accounting.

➤ Accounting Update

The NAS periodically sends Accounting Update packets to the RADIUS server, making the accounting more real-time. The accounting update interval can be provided by the RADIUS server or configured on the NAS.

➤ Accounting End

After a user goes offline, the NAS sends the RADIUS server an accounting end packet carrying the online period and traffic of the user. The RADIUS server generates online records based on the information carried in this packet.

	dot1x stationarity enable	Disables migration of dynamic users.
Configuring Extended Functions	 (Optional) It is used to configure active authentication requests on a port.	
	 (Optional) It is used to configure the authenticated client list.	
	 (Optional) It is used to enable 802.1X packet sending with the pseudo source MAC address.	
	 (Optional) It is used to configure multiple accounts for the same MAC address.	
	dot1x auto-req	Enables active authentication.
	dot1x auto-req packet-num	Configures the number of active authentication requests.
	dot1x auto-req user-detect	Enables user detection for active authentication.
	dot1x auto-req req-interval	Configures the interval of active authentication request.
	dot1x auth-address-table address	Configures the authenticatable client list.
	dot1x pseudo source-mac	Enables 802.1X packets sending with the pseudo source MAC address.
	dot1x multi-account enable	Enables multi-account authentication with one MAC address.
	dot1x valid-ip-acct enable	Enables IP-triggered accounting.
dot1x valid-ip-acct timeout	Configures the timeout of obtaining IP addresses after users get authenticated. If timeout is reached, they will be kicked off.	
dot1x auth-with-order	Enables 802.1X precedence over MAB.	
dot1x user-name compatible	Configures compatibility for H3C 802.1X authentication clients and authentication servers.	

4.4.1 Configuring 802.1X Basic Functions

Configuration Effect

- Enable basic authentication and accounting services.
- On a wired network, run the **dot1x port-control auto** command in interface configuration mode to enable 802.1X authentication on a port.
- Run the **radius-server host ip-address** command to configure the IP address and port information of the RADIUS server and the **radius-server key** command to configure the RADIUS communication key between the NAS and the RADIUS server to ensure secure communication.
- Run the **aaa accounting update** command in global configuration mode to enable accounting update and the **aaa accounting update interval** command on the NAS to configure the accounting update interval. If the RADIUS server

supports accounting update, you can also configure it on the RADIUS server. Prefer to use the parameters assigned by the authentication server than the parameters configured on the NAS.

Notes

- Configure accurate RADIUS parameters so that the basic RADIUS communication is proper.
- The 802.1X authentication method list and accounting method list must be configured in AAA. Otherwise, errors may occur during authentication and accounting.
- Due to chipset restriction on switches, if 802.1X is enabled on one port, all ports will send 802.1X packets to the CPU.
- If 802.1X is enabled on a port but the number of authenticated users exceeds the maximum number of users configured for port security, port security cannot be enabled.
- If port security and 802.1X are both enabled but the security address has aged, 802.1X users must re-initiate authentication requests to continue the communication.
- Users with IP addresses statically configured or compliant with IP-MAC binding can access the network without authentication.
- 802.1X uses the default method list by default. If the default method list is not configured for AAA, run the **dot1x authentication** and **dot1x accounting** commands to reconfigure the it.
- When NX-SAM/SMP is used, accounting must be enabled. Otherwise, the RADIUS server will fail to detect users going offline, causing offline users remaining in the online user table.

Configuration Steps

↳ Enabling AAA

- (Mandatory) 802.1X authentication and accounting take effect only after AAA is enabled.
- Enable AAA on the NAS that needs to control user access by 802.1X.

Command	aaa new-model
Parameter	N/A
Description	
Defaults	AAA is disabled by default.
Command Mode	Global configuration mode
Usage Guide	AAA is disabled by default. This command is mandatory for the deployment of 802.1X authentication.

↳ Enabling an AAA Authentication Method List

- Mandatory.
- The AAA authentication method list must be consistent with the 802.1X authentication method list.
- Enable an AAA authentication method list after 802.1X authentication is enabled on the NAS.

Command	aaa authentication dot1x <i>list-name</i> group radius
Parameter	<i>list-name</i> : Indicates the 802.1X authentication method list of AAA.
Description	
Defaults	No AAA authentication method list is configured by default.
Command Mode	Global configuration mode
Usage Guide	AAA authentication modes are disabled by default. The AAA authentication mode must be consistent with the 802.1X authentication mode.

▾ Configuring the RADIUS Server Parameters

- (Mandatory) The RADIUS server parameters must be configured to ensure proper communication between the NAS and the RADIUS server.
- Configure RADIUS server parameters after 802.1X authentication is enabled on the NAS.

Command	radius-server host <i>ip-address</i> [auth-port <i>port1</i>] [acct-port <i>port2</i>]
Parameter	<i>ip-address</i> : Indicates the IP address of the RADIUS server.
Description	<i>port1</i> : Indicates the authentication port. <i>port2</i> : Indicates the accounting port.
Defaults	No RADIUS server parameters are configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the Preshared Key for Communication between the NAS and RADIUS Server

- (Mandatory) The preshared key for communication between the NAS and RADIUS server must be configured to ensure proper communication between the NAS and the RADIUS server.
- Configure the preshared key of the RADIUS server after 802.1X authentication is enabled on the NAS.

Command	radius-server key <i>string</i>
Parameter	<i>string</i> : Indicates the preshared key.
Description	
Defaults	No preshared key is configured for communication between the NAS and RADIUS server by default.
Command Mode	Global configuration mode
Usage Guide	The IP address of the NAS must be the same as that registered on the RADIUS server. The preshared key on the NAS must be the same as that on the RADIUS server. If the default RADIUS communication ports are changed on the RADIUS server, you need to change the communication ports on the NAS correspondingly.

▾ Enabling 802.1X on a Port

- This command is mandatory for a wired network.

- Enable 802.1X on switches.

Command	dot1x port-control auto
Parameter Description	N/A
Defaults	802.1X is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	802.1X is disabled on a port by default. This command is mandatory for the deployment of 802.1X authentication. The default method list is used by default. If the 802.1X authentication method list in AAA is not the default one, the configured 802.1X authentication method list should match.

Verification

Start Nodexon Supplicant, enter the correct account information, and initiate authentication. Then check whether the 802.1X and RADIUS configurations are correct.

↳ Checking for 802.1X Authentication Entries

Command	show dot1x summary
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Display entries of authenticated users to check the authentication status of users, for example, authenticating, authenticated, or quiet.
Command Display	<pre>Nodexon#show dot1x summary ID Username MAC Interface VLAN Auth-State Backend-state Port-Status User-Type Time ----- 16777302 ts-user b048.7a7f.f9f3 wlan 1 1 Authenticated Idle Authed static 0days 0h 0m12s</pre>

↳ Checking for AAA User Entries

Command	show aaa user all
Parameter Description	N/A
Command Mode	Privileged EXEC mode/Global configuration mode/Interface configuration mode
Usage Guide	Display information of AAA users.
Command	Nodexon#show aaa user all

Display	<pre> Id ----- Name 2345687901 wwxy </pre>
----------------	---

- Check whether the RADIUS server responds to authentication based on the RADIUS packets between the NAS and the RADIUS server. If no, it means that the network is disconnected or parameter configurations are incorrect. If the RADIUS server directly returns a rejection reply, check the log file on the RADIUS server to identify the cause, e.g., of the authentication mode of the authentication server is incorrectly configured.

Configuration Example

i In this example, NX-SAM acts as the authentication server.

Configuring 802.1X Authentication on a Switch

Scenario	<p>Figure 4-5</p>
Configuration Steps	<ul style="list-style-type: none"> ● Register the IP address of the switch on the RADIUS server and configure the communication key between the switch and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the switch. ● Configure RADIUS parameters on the switch. ● Enable 802.1X authentication on ports of the switch. <p>Switch configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>
	<pre> Nodexon# configure terminal Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1 </pre>
	<pre> Nodexon (config-if)# dot1x port-control auto </pre>
Verification	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username:tests-user,password:test. ● The user fails to ping 192.168.32.120 before authentication. ● After the user enters account information and click Authenticate on Nodexon Supplicant, the

authentication succeeds and the user can successfully ping 192.168.32.120.							
<ul style="list-style-type: none"> Information of the authenticated user is displayed. Nodexon# show dot1x summary 							
ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State	
Port-Status	User-Type	Time					
16778217	ts-user	0023.aeea.4286	Fa0/1	2	Authenticated	Idle	Authed
static	0days 0h 0m 7s						

Common Errors

- RADIUS parameters are incorrectly configured.
- The RADIUS server has a special access policy, for example, the RADIUS packets must carry certain attributes.
- The AAA authentication mode list is different from the 802.1X authentication mode list, causing authentication failure.

4.4.2 Configuring 802.1X Parameters

Configuration Effect

- Adjust 802.1X parameter configurations based on the actual network situation. For example, if the authentication server has poor performance, you can raise the authentication server timeout.

Notes

- 802.1X and RADIUS have separate server timeouts. By default, the authentication server timeout of 802.1X is 5 seconds while that of RADIUS is 15 seconds. In actual situations, ensure that the former is greater than the latter. You can run the **dot1x timeout server-timeout** command to adjust the authentication server timeout of 802.1X. For detailed configuration about the RADIUS server timeout, see the *Configuring RADIUS*.
- Online client detection applies only to Nodexon Supplicant.

Configuration Steps

📌 Enabling Re-authentication

- (Optional) After re-authentication is enabled, the NAS can periodically re-authenticate online users.
- Enable re-authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x re-authentication
Parameter	N/A
Description	
Defaults	Re-authentication is disabled by default.
Command Mode	Global configuration mode

Usage Guide	You can run this command to periodically re-authenticate users.
--------------------	---

▾ Configuring the Re-authentication Interval

- (Optional) You can configure the re-authentication interval for users.
- Configure the re-authentication interval after 802.1X authentication is enabled on the NAS. The re-authentication interval takes effect only after re-authentication is enabled.

Command	dot1x timeout re-authperiod <i>period</i>
Parameter Description	<i>period</i> : Indicates the re-authentication interval in the unit of seconds.
Defaults	The default value is 3,600 seconds.
Command Mode	Global configuration mode
Usage Guide	Adjust the re-authentication interval as required.

▾ Configuring the Interval of EAP-Request/Identity Packet Retransmission

- (Optional) A larger value indicates a longer interval of packet retransmission.
- Configure the interval of EAP-Request/Identity packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout tx-period <i>period</i>
Parameter Description	<i>period</i> : Indicates the interval of EAP-Request/Identity packet retransmission in the unit of seconds.
Defaults	The default value is 3 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Adjust the value based on how long the authentication client responds to the NAS's requests.

▾ Configuring the Maximum Times of EAP-Request/Identity Packet Retransmission

- (Optional) A larger value indicates more frequent retransmissions.
- Configure the maximum times of EAP-Request/Identity packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x reauth-max <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum times of EAP-Request/Identity packet retransmission.
Defaults	The default value is 3 for switches
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. In the case of high-rate packet loss, increase this value so that the clients can easily receive packets from the NAS.

✚ Configuring the Interval of EAP-Request/Challenge Packet Retransmission

- (Optional) A larger value indicates a longer retransmission interval.
- Configure the interval of EAP-Request/Challenge packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout supp-timeout <i>time</i>
Parameter Description	<i>time</i> : Indicates the interval of EAP-Request/Challenge packet transmission in the unit of seconds.
Defaults	The default value is 3 seconds for switches
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value in the case of high-rate packet loss.

✚ Configuring the Maximum Times of EAP-Request/Challenge Packet Retransmission

- (Optional) A larger value indicates more frequent retransmissions.
- Configure the maximum times of EAP-Request/Challenge packet retransmission after 802.1X authentication is enabled on the NAS.

Command	dot1x max-req <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum times of EAP-Request/Challenge packet retransmission in the unit of seconds.
Defaults	The default value is 3.
Command Mode	Global configuration mode
Usage Guide	Optional. It is recommended to use the default value. Increase this value in the case of high-rate packet loss.

✚ Configuring the Authentication Server Timeout

- (Optional) A larger value indicates a longer authentication server timeout.
- Configure the authentication server timeout after 802.1X authentication is enabled on the NAS.
- The server timeout of RADIUS must be greater than that of 802.1X.

Command	dot1x timeout server-timeout <i>time</i>
Parameter Description	<i>time</i> : Indicates the authentication server timeout in the unit of seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value if the communication between the NAS and RADIUS server is unstable.

✚ Configuring the Quiet Period after Authentication Fails

- (Optional) A larger value indicates a longer quiet period.
- Configure the quiet period after 802.1X authentication is enabled on the NAS.

Command	dot1x timeout quiet-period <i>time</i>
Parameter Description	<i>time</i> : Indicates the quiet period after authentication fails. The unit is second.
Defaults	The default value is 10 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Increase this value to prevent users from frequently initiating authentication to the RADIUS server, thereby reducing the load of the authentication server.

✚ Specifying the Authentication Mode

- (Optional) Configure the mode for 802.1X authentication.
- Configure the authentication mode after 802.1X authentication is enabled on the NAS.

Command	dot1x auth-mode {eap chap pap}
Parameter Description	eap : Indicates EAP authentication. chap : Indicates CHAP authentication. pap : Indicates PAP authentication.
Defaults	The default value is eap .
Command Mode	Global configuration mode
Usage Guide	Select the authentication mode supported by Nodexon Supplicant and authentication server.

✚ Enabling Online Nodexon Client Detection

- (Optional) If online Nodexon client detection is enabled, the NAS can find clients going offline in a timely manner to prevent incorrect accounting.
- This function applies only to Nodexon 802.1X authentication clients.
- Enable online Nodexon client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x client-probe enable
Parameter Description	N/A
Defaults	Online Nodexon client detection is disabled by default.
Command Mode	Global configuration mode
Usage Guide	It is recommended to enable this function when Nodexon Supplicant is used.

↘ Configuring the Interval of Online Nodexon Client Detection

- (Optional) A larger value indicates a longer time interval at which Nodexon clients send detection packets.

- Configure the interval of online Nodexon client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x probe-timer interval <i>time</i>
Parameter Description	<i>time</i> : Indicates the time interval at which Nodexon Supplicant sends a heartbeat packet to the NAS. The unit is second.
Defaults	The default value is 20 seconds.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value.

↘ Configuring the Duration of Online Nodexon Client Detection

- (Optional) A larger value indicates a longer interval at which the NAS finds clients going offline.

- Configure the duration of online Nodexon client detection after 802.1X authentication is enabled on the NAS.

Command	dot1x probe-timer alive <i>time</i>
Parameter Description	<i>time</i> : Indicates the duration of online Nodexon client detection in the unit of seconds.
Defaults	The default value is 250 seconds.
Command Mode	Global configuration mode
Usage Guide	Optional. If the NAS does not receive any detection packets from an online client within the detection duration, it regards the client offline. It is recommended to use the default value.

Verification

Run the **show dot1x** command to check whether parameter configurations take effect.

Configuration Example

↘ Specifying the Authentication Mode

Scenario	The NAS is deployed in standalone mode.
Configuration Steps	Set the authentication mode to chap .
	<pre>Nodexon(config)#dot1x auth-mode chap</pre>
Verification	Display the configurations. <pre>Nodexon(config)#show dot1x 802.1X basic information:</pre>

	<pre> 802.1X Status enable Authentication Mode chap Authorization mode disable Total User Number 0 (exclude dynamic user) Authenticated User Number 0 (exclude dynamic user) Dynamic User Number 0 Re-authentication disable Re-authentication Period 3600 seconds Re-authentication max 3 times Quiet Period 10 seconds Tx Period 30 seconds Supplicant Timeout 3 seconds Server Timeout 5 seconds Maximum Request 3 times Client Online Probe disable Eapol Tag disable 802.1x redirect disable Private supplicant only disable </pre>
--	--

➤ **Enabling Online Client Detection**

<p>Scenario</p> <p>Figure 4-6</p>	
<p>Configuration Steps</p>	<p>Enable online client detection.</p> <pre>Nodexon(config)#dot1x client-probe enable</pre> <ul style="list-style-type: none"> Users can remain online only when their Nodexon Supplicant sends online detection packets as scheduled.
<p>Verification</p>	<ul style="list-style-type: none"> Display the configurations. <pre>Nodexon(config)#show dot1x</pre> <p>802.1X basic information:</p> <pre>802.1X Status enable</pre>

```

Authentication Mode ..... chap
Authorization mode ..... disable
Total User Number ..... 0 (exclude dynamic user)
Authenticated User Number ..... 0 (exclude dynamic user)
Dynamic User Number ..... 0
Re-authentication ..... disable
Re-authentication Period ..... 3600 seconds
Re-authentication max ..... 3 times
Quiet Period ..... 10 seconds
Tx Period ..... 30 seconds
Supplicant Timeout ..... 3 seconds
Server Timeout ..... 5 seconds
Maximum Request ..... 3 times
Client Online Probe ..... enable
Eapol Tag ..... disable
802.1x redirect ..... disable

```

Common Errors

- The server timeout is shorter than the RADIUS timeout.
- Online client detection is enabled but the authentication program is not Nodexon Supplicant.

4.4.3 Configuring Authorization

Configuration Effect

- In IP authorization, authenticated users have to use the specified IP addresses to access the network, preventing IP address fake. IP authorization can be enabled in global configuration mode or interface configuration mode. IP authorization enabled in interface configuration mode takes priority over that configured in global configuration mode.
- Enable non-Nodexon client filtering. If this function is enabled, users must use Nodexon Supplicant for authentication so that they will enjoy services provided by Nodexon Supplicant, such as anti-proxy or SMS.
- Enable Web redirection to support 2G Nodexon Supplicant deployment. 2G Nodexon Supplicant deployment means that a user needs to download Nodexon Supplicant through the browser and then initiate authentication through Nodexon Supplicant.
2G Nodexon Supplicant deployment facilitates quick deployment of Nodexon Supplicant in the case of massive users.

Notes

- If the real-time kickoff function of NX-SAM/SMP is used, you need to configure correct SNMP parameters. For details, see the *Configuring SNMP*.
- If multiple authentication supplicants are used, disable this function.
- If the IP authorization mode is changed, all authenticated users will go offline and have to get re-authenticated before online again.

- In mixed authorization mode, IP authorization with a higher priority is used during user authentication. For example, if Nodexon Supplicant provides an IP address for this RADIUS-authentication user during its re-authentication, this IP address will be used for authorization.
- 2G Nodexon Supplicant deployment and Web authentication cannot be used at the same time.
- 2G Nodexon Supplicant deployment requires the setting of the **redirect** parameter. For details, see the *Configuring Web Authentication*.
- The kickoff function of NX-SAM/SMP is implemented through SNMP. Therefore, you need to configure SNMP parameters. For details, see the *Configuring SNMP*.

Configuration Steps

▾ Specifying the Global IP Authorization Mode

- The **supplicant** mode only applies to Nodexon Supplicant.
- In **radius-server** mode, the authentication server needs to assign IP addresses based on the **framed-ip** parameters.
- In **dhcp-server** mode, DHCP snooping must be enabled on the NAS.
- (Optional) Configure an IP-MAC binding.
- Configure the IP authorization mode after 802.1X authentication is enabled on the NAS.

Command	aaa authorization ip-auth-mode { disable supplicant radius-server dhcp-server mixed }
Parameter Description	disable: Disables IP authorization. supplicant: Indicates IP authorization by the supplicant. radius-server: Indicates IP authorization by the RADIUS server. dhcp-server: Indicates IP authorization by the DHCP server. mixed: Indicates IP authorization in a mixed manner.
Defaults	IP authorization is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Select the IP authorization mode based on actual deployment.

▾ Enabling Web Redirection for 2G Nodexon Supplicant Deployment

- (Optional) If the redirection for 2G Nodexon Supplicant deployment is enabled, users not having any 802.1X authentication clients on a controlled port can download and install an 802.1X authentication client through Web pages.
- Enable Web redirection for 2G Nodexon Supplicant deployment after 802.1X authentication is enabled on the NAS.
- The **redirect** parameter must be configured. For details, see the *Configuring Web Authentication*.

Command	dot1x redirect
Parameter Description	N/A
Defaults	The redirection for 2G Nodexon Supplicant deployment is disabled by default.

Command Mode	Global configuration mode
Usage Guide	The redirect parameter must be configured. For details, see the <i>Configuring Web Authentication</i> .

↘ **Enabling Non-Nodexon Client Filtering**

- (Optional) If this function is enabled, non-Nodexon clients cannot perform authentication.

- Enable non-Nodexon client filtering after 802.1X authentication is enabled on the

Command	dot1x private-supplicant-only
Parameter Description	N/A
Defaults	Non-Nodexon client filtering is disabled by default.
Command Mode	Global configuration mode
Usage Guide	This function can be enabled only when Nodexon Supplicant is used.

Verification

- After IP authorization is enabled, use the client to initiate authentication and go online, and then change the IP address. As a result, the client cannot access the network.
- Enable Web redirection for 2G Nodexon Supplicant deployment. When you start the browser to visit a website, the system automatically redirects to the download Web page and downloads the authentication client. You can access the network only when authenticated by the client.
- After a user is authenticated and goes online, enable the kickoff function on NXSAM/SMP. The NAS will force the user offline and the user will fail to access the network.

Configuration Example

↘ **Configuring the IP Authorization Mode**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable AAA. ● Configure RADIUS. ● Enable 802.1X on a controlled port. ● Globally enable IP authorization in supplicant mode.
	<pre>Nodexon(config)#aaa authorization ip-auth-mode supplicant</pre>
	<ul style="list-style-type: none"> ● Nodexon Supplicant initiates authentication and the authentication succeeds.
<p>Verification</p>	<ul style="list-style-type: none"> ● Nodexon Supplicant only uses 192.168.217.82 for communication. ● Display the configurations. <pre>Nodexon(config)#show dot1x user name ts-user Supplicant information: MAC address b048.7a7f.f9f3 Username ts-user User ID 16777303 Type static VLAN 1 Port wlan 1 Online duration 0days 0h 0m21s Up average bandwidth 0 kBps Down average bandwidth 0 kBps Authorized VLAN 1 Authorized session time 20736000 seconds Authorized flux unlimited Accounting No Proxy user Permit Dial user Permit IP privilege 0 Private supplicant no Max user number on this port 0 Authorization ip address 192.168.217.82</pre>

Common Errors

- There are multiple authentication clients on the network but non-Nodexon client filtering is enabled, causing some users to fail authentication.
- NX-SAM/SMP is used but SNMP parameters are not configured on the switch, causing kickoff failure.
- The **redirect** parameter is incorrectly configured, causing abnormalities in redirection for 2G Nodexon Supplicant downloading.

4.4.4 Configuring MAB

Configuration Effect

- If the MAC address of an access user is used as the authentication account, the user does not need to install any supplicants. This applies to some dumb users such as networking printers.
- Single-user MAB applies to two scenarios:
 - There is only one dumb user connected to a port.
 - Only one user needs to be authenticated. After this, all other users can access the network.
- Multi-user MAB applies to the scenario where multiple dumb users connected to a port. For example, multiple VoIP devices are deployed in the network call center.
- Multi-user MAB can be used with 802.1X authentication. It applies to mixed access scenarios such as the PC-VoIP daisy-chain topology.

Notes

- A MAB-enabled port sends an authentication request packet as scheduled by **tx-period**. If the number of the sent packets exceeds the number specified by **reauth-max** but still no client responds, this port enters the MAB mode. Ports in MAB mode can learn the MAC addresses and use them as the account information for authentication.
- When using the MAC address as the user name and password on the authentication server, delete all delimiters. For example, if the MAC address of a user is 00-d0-f8-00-01-02, the user name and password should be set to 00d0f8000102 on the authentication server.
- 802.1X takes priority over MAB. Therefore, if a user having passed MBA authentication uses a client to initiate 802.1X authentication, MAB entries will be removed.
- MAB supports only PAP authentication. PAP authentication should be enabled also on the authentication server.
- Only when active authentication is enabled, can MAB detect whether the user can perform 802.1X authentication. Therefore, automatic authentication must be enabled for MAB deployment.

Configuration Steps

📌 Enabling Single-User MAB

- Optional.
- Single-user MAB applies when only one user connected to a port needs to be authenticated.
- Enable single-user MAB on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass
Parameter	N/A
Description	
Defaults	Single-user MAB is disabled by default.
Command	Interface configuration mode

Mode	
Usage Guide	This command applies only to switches. Single-user MAB applies when only one dumb user connected to a port needs to be authenticated. If you want to restrict the number of users, enable the violation mode.

▾ Configuring the Timeout of MAB Users

- Optional.
- After a MAC address in MAB mode is authenticated and goes online, the NAS regards the MAC address online unless re-authentication fails, the port goes down, or the MAC address goes offline due to management policies such as kickoff. You can configure the timeout of authenticated MAC addresses. The default value is 0, indicating always online.
- Configure the timeout of MAB users on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass timeout-activity <i>value</i>
Parameter Description	<i>value</i> : Indicates the maximum online time of MAB users in the unit of seconds.
Defaults	The default value is 0, indicating no time restriction.
Command Mode	Interface configuration mode
Usage Guide	The MAB timeout applies to both single-user MAB and multi-user MAB.

▾ Enabling the MAB Violation Mode

- Optional.
- Enable MAB violation on the 802.1X controlled port of the NAS.
- By default, after one MAC address passes MAB authentication, data of all switches connected to the port can be forwarded. However, for security purposes, the administrator may request one MAB port to support only one MAC address. In this case, you can enable MAB violation on the port. If more than one MAC address is found connected to a MAB violation-enabled port after the port enters MAB mode, the port will become a violation.

Command	dot1x mac-auth-bypass violation
Parameter Description	N/A
Defaults	MAB violation is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Configure this command only when only one dumb user is connected to the port. MAB violation applies only to single-user MAB.

▾ Enabling Multi-user MAB

- Optional.
- Enable multi-user MAB on the 802.1X controlled port of the NAS.

Command	dot1x mac-auth-bypass multi-user
Parameter	N/A
Description	
Defaults	Multi-user MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Configure this command when multiple dumb users connected to the port need to be authenticated.

▾ Configuring the Quiet Period after Multi-user MAB Fails

- Optional.
- Configure the quiet period of the multi-user MAB failure after multi-user MAB is enabled on the NAS.
- If multi-user MAB is enabled, you should prohibit unauthorized users from frequently initiating authentication to protect the NAS from attacks of these users and thereby reduce the load of the authentication server. Configure the quiet period of the multi-user MAB failure in global configuration mode. That is, if a MAC address fails authentication, it needs to re-initiate authentication after the quiet period. Configure this quiet period based on the actual situation. The default value is 0, indicating that a user can re-initiate authentication immediately after authentication fails.

Command	dot1x multi-mab quiet-period <i>value</i>
Parameter Description	<i>value</i> : Indicates the quiet period after authentication fails.
Defaults	The default value is 0s.
Command Mode	Global configuration mode
Usage Guide	This command applies only to switches. If too many dumb users connected to a port are authenticated, run this command to limit the authentication rate.

▾ Configuring VLAN-based MAB

- Optional.
- Enable VLAN-based MAB after multi-user MAB is enabled on the NAS.
- If you configure VLANs as MAB VLANs, only users in these VLANs can perform MAB.

Command	dot1x mac-auth-bypass vlan <i>vlan-list</i>
Parameter Description	<i>vlan-list</i> : Indicates the VLANs supporting MAB.
Defaults	VLAN-based MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies only to switches. Run this command when a port allows only users in specified VLANs to perform MAB.

Verification

Check whether the dumb user can access the network. If yes, MAB takes effect. If no, MAB does not take effect.

- Check whether MAB functions are configured on the authentication server and NAS.
- Check whether dumb users with illegitimate MAC addresses cannot access the network.
- Check whether dumb users with illegitimate MAC addresses can access the network.

Configuration Example

▾ Enabling Multi-user MAB on a Switch

<p>Scenario</p> <p>Figure 4-8</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the Switch A on the RADIUS server and configure the communication key between Switch A and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on Switch A. ● Configure RADIUS parameters on Switch A. ● Enable 802.1X and multi-user MAB on a port of Switch A. <p>Switch configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>
	<pre>Nodexon# configure terminal Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1 Nodexon (config-if)# dot1x port-control auto Nodexon (config-if)# dot1x mac-auth-bypass multi-user</pre>
<p>Verification</p>	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username: 0023aeaa4286,password: 0023aeaa4286. ● The user fails to ping 192.168.32.120 before authentication. ● The user connects to the switch, the authentication succeeds, and the user can successfully ping 192.168.32.120.

● Information of the authenticated user is displayed. `Nodexon# show dot1x summary`

ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State
Port-Status	User-Type	Time				
16778217	0023aea...	0023.aeaa.4286	Fa0/1	2	Authenticated	Idle
static	0days 0h 5m 8s					Authed

4.4.5 Configuring MAB Auto Authentication

Configuration Effect

- When a STA accesses the network for the first time, Web authentication is performed. When the STA is disconnected from and then reconnects to the network, authentication is not required.

Notes

- Wireless MAB authentication is triggered by a STA advertisement. If a STA is already online, MAB authentication will not be triggered again. MAB authentication is triggered only after the STA is disconnected from and then reconnects to the network.
- When a STA accesses the network for the second time, a dialog box may be displayed for MAB authentication. When the STA accesses the network for the third time, the dialog box will not be displayed.
- If MAB authentication fails, a dialog box is displayed for Web authentication when the STA accesses the network next time.

Configuration Steps

For details about Web authentication configuration, see the Web authentication configuration document. For details about MAB authentication configuration, see section “Configuring MAB”.

Configuration Example

Configuring MAB Auto Authentication

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server and bind it with a MAC address for imperceptible authentication. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable 802.1X authentication and MAB authentication on an interface of the NAS. ● Enable second-generation (or first-generation/embedded) Web authentication on an interface of the NAS and configure the Web authentication template globally. <p>The following describes the NAS configurations. For detailed configuration on the RADIUS server, see the related configuration guide (The following describes configuration on the switch, which is similar to that on the AC/AP, except that the configuration on the switch is performed in interface configuration mode instead of WLAN RSNA configuration mode.)</p>
	<pre>Nodexon#configureterminal Nodexon (config)#aaa new-model Nodexon (config)#aaa authentication web-auth default group radius Nodexon (config)#aaa authentication dot1x default group radius Nodexon (config)aaa accounting net-work default start-stop group radius Nodexon (config)#radius-server host 192.168.32.120 Nodexon (config)#radius-server key Nodexon Nodexon (config)#web-auth template eportalv2 Nodexon (config-tmplt-v2)#ip 192.158.32.9 Nodexon (config-tmplt-v2)#urlhttp://192.168.32.9:8080/eportal/index.jsp Nodexon (config-tmplt-v2)#exit Nodexon (config)#interface FastEthernet 0/1 Nodexon (config-if)#dot1x port-control auto Nodexon (config-if)#dot1x mac-auth-bypass multi-user Nodexon (config-if)#web-auth enable eportalv2</pre>
<p>Verification</p>	<p>Check whether authentication is normal and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, for example, the username is 0023aeaa4286 and the password is 0023aeaa4286. ● The STA fails to ping 192.168.32.120 before authentication. ● The STA connects to the NAS, a page indicating the authentication succeeds is displayed, and the STA can successfully ping 192.168.32.120.

- The STA is disconnected from and then reconnects to the network and can successfully ping 192.168.32.120.

```
Nodexon#show dot1x summary
```

ID	Username	MAC	Interface	VLAN	Auth-State
Backend-State	Port-Status	User-Type	Time		
16778217	0023aea...	0023.aeaa.4286	Fa0/1	2	Authenticated
Authed	static	0days 0h 5m 8s			Idle

Common Errors

- The MAC account format is incorrect on the authentication server.

4.4.6 Configuring IAB

Configuration Effect

- Enable IAB. After IAB is enabled, newly authenticated users can access the network even when all RADIUS servers configured on the NAS are inaccessible.
- Enable IAB recovery. When RADIUS servers recover to their reachable status, re-verify the users authorized during inaccessibility.
- Configure IAB VLANs. When RADIUS servers are inaccessible and cannot authenticate users temporarily, you can add the ports connected with users to specified VLANs so that users can access only network resources of specified VLANs.

Notes

- Configure an account and standards for testing RADIUS server accessibility. For details, see the *Configuring RADIUS*.
- IAB takes effect only when only RADIUS authentication exists in the globally configured 802.1X authentication mode list and all RADIUS servers in the list are inaccessible. If other authentication modes (for example, local and none) exist in the list, IAB does not take effect.
- After multi-domain AAA is enabled, 802.1X authentication does not need the globally configured authentication mode list any more. If IAB detects that all RADIUS servers configured in the globally configured 802.1X authentication mode list are inaccessible, it directly returns an authentication success reply to users, with no need to enter the user name. Therefore, multi-domain AAA does not take effect on this port.
- Users authenticated in IAB mode do not need to initiate accounting requests to the accounting server.
- Authenticated users can properly access the network, not affected by server inaccessibility.

- In access authentication configuration mode, when 802.1X-based IP authentication is enabled globally, users on this port, except those having been authenticated, cannot be authenticated in IAB mode. In gateway authentication mode, users are IP authorized if their IP addresses are obtained.
- Complete 802.1X authentication is required on such 802.1X authentication clients as those of Windows. It is possible that though these clients already pass the IAB authentication, there are prompts on the clients suggesting failed authentication.
- If the failed VLAN configured does not exist, a failed VLAN will be dynamically created when a port enters the failed VLAN and automatically removed when the port exits the failed VLAN.
- Failed VLANs cannot be private VLANs, remote VLANs, and super VLANs (including sub VLANs).

Configuration Steps

▾ Enabling IAB

- (Optional) After IAB is enabled, the NAS authorizes newly authenticated users if the authentication server is faulty.
- Enable IAB after 802.1X authentication is enabled on the NAS.

Command	dot1x critical
Parameter	N/A
Description	
Defaults	IAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	This command applies to ports on which newly authenticated users need to be authorized when the authentication server is inaccessible.

▾ Enabling IAB Recovery

- (Optional) After the authentication server is recovered, the NAS re-authenticates users that are authorized when the authentication server is inaccessible.
- Enable IAB recovery actions after 802.1X authentication is enabled on the NAS.

Command	dot1x critical recovery action reinitialize
Parameter	N/A
Description	
Defaults	IAB recovery is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	If IAB recovery is enabled on a port, properly authenticated users on the port can access the network without re-authentication after the authentication server is recovered. After the authentication server is recovered, the NAS initiates authentication only to users authenticated in IAB mode during server inaccessibility.

▾ Configuring the IAB VLAN

- (Optional) Configure the VLAN on which newly authenticated users are authorized when the authentication server becomes inaccessible.
- Enable VLAN-based IAB after 802.1X authentication is enabled on the NAS.

Command	dot1x critical vlan <i>vlan-id</i>
Parameter Description	<i>vlan-id</i> : Indicates the VLAN to redirect when the authentication server becomes inaccessible.
Defaults	The IAB VLAN is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	Configure the IAB VLAN so that temporary network resources can be provided for users when servers are inaccessible.

Verification

- When the authentication server is accessible, check whether users can go online only by using the correct user name and password.
- When the authentication server is inaccessible, check whether new users can be authorized to access the network immediately after connecting to the NAS.

Configuration Example

▾ Enabling IAB

<p>Scenario</p> <p>Figure 4-10</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters and enable server accessibility probe on the NAS. ● Enable 802.1X and multi-user MAB on a port of the NAS. <p>NAS configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p> <pre>Nodexon# configure terminal</pre>

	<pre>Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1</pre>
	<pre>Nodexon (config-if)# dot1x port-control auto</pre>
Verification	<p>Check whether authentication is proper and network access behaviors change after authentication.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username: test,password: test. ● When the authentication server is accessible, the user fails to ping 192.168.32.120 before authentication. ● When the authentication server becomes inaccessible, the user connects to the NAS, authentication succeeds, and the user can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed.Nodexon# show dot1x summary <pre>ID Username MAC Interface VLAN Auth-State Backend-State Port-Status User-Type Time ----- ----- ----- 16778217 test 0023.aeea.4286 Fa0/1 2 Authenticated Idle Authed static 0days 0h10m20s</pre>

4.4.7 Configuring Port Control

Configuration Effect

- By default, the 802.1X controlled port is controlled based on the MAC address. That is, users using this MAC address can access the network only after authenticated.
- Configure the port-based control mode. As long as a user on a controlled port passes authentication, this port becomes authenticated and all users connected to this port can properly access the network.
- Configure the single-user control mode on a port. This port allows only a single user to pass authentication. If this port becomes authenticated, this user can properly access the network. At this time, if the NAS detects other users connected to this port, it will clear all users connected to this port and the user needs to re-initiate authentication.
- The port-based control mode allows or prohibits dynamic users migrating among different ports. By default, dynamic users can migrate among different ports.

Notes

- In port-based authentication mode, a controlled port supports only one authenticated user while all others are dynamic users.
- In single-user port-based authentication mode, only one user on a controlled port can pass authentication and access the network. This restriction remains even when a specified number of users is configured on this port.

Configuration Steps

▾ Enabling the MAC-based Control Mode

- (Optional) After the MAC-based control mode is enabled, each user on an 802.1X controlled port must pass MAC-based authentication to access the network.
- Enable the MAC-based control mode after 802.1X authentication is enabled on the NAS.

Command	dot1x port-control-mode mac-based
Parameter Description	N/A
Defaults	The default port control mode is MAC-based control.
Command Mode	Interface configuration mode
Usage Guide	Configure the MAC-based control mode if all the users on a controlled port have to pass authentication to access the network.

▾ Enabling the Port-based Control Mode

- (Optional) After a user on an 802.1X controlled port passes authentication, all other users on this port can access the network.
- Enable the port-based control mode after 802.1X authentication is enabled on the NAS.

Command	dot1x port-control-mode port-based
Parameter Description	N/A
Defaults	The default port control mode is MAC-based control.
Command Mode	Interface configuration mode
Usage Guide	You can configure the port-based control mode if the remaining users can access the network after a user on a controlled port passes authentication.

▾ Enabling the Single-User Port-based Control Mode

- (Optional) Configure only one dynamic user to access the network in port-based authentication mode.
- Enable the single-user port-based control mode after 802.1X authentication is enabled on the NAS.

Command	dot1x port-control-mode port-based single-host
Parameter Description	N/A
Defaults	The single-user port-based control mode is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when only the authenticated user can act as a dynamic user in port-based control mode.

Disabling Migration of Dynamic Users

- (Optional) If this function is disabled, dynamic users on a controlled port cannot migrate to other ports until the port has aged.
- Disable this function after 802.1X authentication is enabled on the NAS.

Command	<code>dot1x stationarity enable</code>
Parameter	N/A
Description	
Defaults	Dynamic users can migrate to other ports by default.
Command Mode	Global configuration mode
Usage Guide	Configure this command to prohibit dynamic users on a controlled port from migrating to other ports.

Verification

- In MAC-based control mode, each user on a controlled port can access the network only after authenticated.
- In port-based control mode, as long as a user on a controlled port passes authentication, other users can access the network without authentication.

Configuration Example

Enabling the Port-based Control Mode

<p>Scenario Figure 4-11</p>	<p>The diagram illustrates a network setup for 802.1X authentication. A central Switch is connected to three main components: a Hub, a Radius Server, and the Internet. The Hub is connected to the Switch via interface F0/1 and has IP address 192.168.217.83. The Radius Server is connected to the Switch via interface F0/23 and has IP address 192.168.32.120. The Internet is connected to the Switch via interface F0/24 and has IP address 192.168.217.81. A laptop and a server (SU) are connected to the Hub. The SU has IP address 192.168.217.82.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable 802.1X authentication on ports of the NAS. ● Enable port-based authentication on a controlled port. <p>NAS configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>

	<pre>Nodexon# configure terminal Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1 Nodexon (config-if)# dot1x port-control auto Nodexon (config-if)# dot1x port-control-mode port-based</pre>																																										
<p>Verification</p>	<p>Check whether authentication is proper, network access behaviors change after authentication, and dynamic users can access the network.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username:tests-user,password:test. ● The user fails to ping 192.168.32.120 before authentication. ● After the user enters account information and click Authenticate on Nodexon Supplicant, the authentication succeeds and the user can successfully ping 192.168.32.120. ● After passing authentication, dynamic users can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed.Nodexon# show dot1x summary <table border="1" data-bbox="363 856 1432 1226"> <thead> <tr> <th>ID</th> <th>Username</th> <th>MAC</th> <th>Interface</th> <th>VLAN</th> <th>Auth-State</th> <th>Backend-State</th> </tr> <tr> <th>Port-Status</th> <th>User-Type</th> <th>Time</th> <th></th> <th></th> <th></th> <th></th> </tr> </thead> <tbody> <tr> <td>16778217</td> <td>ts-user</td> <td>0023.aeea.4286</td> <td>Fa0/1</td> <td>2</td> <td>Authenticated</td> <td>Idle</td> </tr> <tr> <td>static</td> <td>0days 2h17m29s</td> <td></td> <td></td> <td></td> <td></td> <td>Authed</td> </tr> <tr> <td>none</td> <td>N/A</td> <td>0023.aeea.4286</td> <td>Fa0/1</td> <td>2</td> <td>Authenticated</td> <td>Idle</td> </tr> <tr> <td>Dynamic</td> <td>N/A</td> <td></td> <td></td> <td></td> <td></td> <td>Authed</td> </tr> </tbody> </table>	ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State	Port-Status	User-Type	Time					16778217	ts-user	0023.aeea.4286	Fa0/1	2	Authenticated	Idle	static	0days 2h17m29s					Authed	none	N/A	0023.aeea.4286	Fa0/1	2	Authenticated	Idle	Dynamic	N/A					Authed

Dynamic	N/A					Authed																																					

4.4.8 Configuring Dynamic VLAN Assignment

Configuration Effect

- Enable 802.1X-based dynamic VLAN assignment for a port. If the authentication server assigns a VLAN to redirect after a user passes authentication, the NAS can add this user to the assigned VLAN to perform authorization on this user.
- Controlled ports on the VLAN to redirect fall in three types: Access, Trunk, and Hybrid (MAC VLAN is disabled). You can change native VLANs of these ports to realize 802.1X-based dynamic VLAN assignment.
- If controlled ports on the VLAN to redirect are Hybrid ports (and MAC VLAN is enabled), dynamically create MAC VLAN entries to add users to the assigned VLAN.

Notes

- The NAS can extend RADIUS attributes to assign VLANs. When assigning VLANs to the access switch based on extended attributes, the RADIUS server encapsulates these attributes in RADIUS Attribute 26, with the vendor ID of

0x00001311. The default type No. of the extended attribute is 4. You can run the **radius attribute 4 vendor-type type** command on the NAS to receive the VLAN of which the extended attribute type No. is set to **type**. For details about the command, see the *Configuring RADIUS*.

- The RADIUS server can assign VLANs based on the following RADIUS attributes:
 - Attribute 64: Tunnel-Type, with the value being VLAN (13).
 - Attribute 65: Tunnel-Medium-Type, with the value being 802 (6).
 - Attribute 81: Tunnel-Private-Group-ID, which can be the VLAN ID or VLAN name.
- The NAS can perform 802.1X authentication on Access, Trunk, and Hybrid ports. If 802.1X-based dynamic VLAN assignment is enabled on other ports, authentication will fail.
- If the assigned VLAN is the VLAN name, the system checks whether the VLAN name exists on the access switch. If yes, the port of the user redirects to this VLAN. If no, the NAS identifies the assigned VLAN as the VLAN ID. If the VLAN ID is valid (in the VLAN ID range supported by the system), the port of the user redirects to this VLAN. If the VLAN ID is 0, no VLAN information is assigned. In other cases, users fail authentication.
- Private VLANs, remote VLANs, or super VLANs (including sub VLANs) cannot be assigned for redirection.
- In dynamic VLAN assignment on an Access port, check whether any assigned VLAN is configured on the switch:
 - Yes: If the Access port can redirect to the assigned VLAN, the port will leave the configured VLAN and migrate to the assigned VLAN, and user authentication will succeed. Otherwise (see the related description below), user authentication will fail.
 - No: If the NAS identifies the assigned VLAN attribute as the VLAN ID, it will create a VLAN and enable the port to redirect to the new VLAN, and user authentication will succeed. If the NAS identifies the assigned VLAN attribute as the VLAN name, it will fail to find the corresponding VLAN ID, causing authentication failure.
- In dynamic VLAN assignment on a Trunk port, check whether any assigned VLAN is configured on the switch:
 - Yes: If the Trunk port can redirect to the assigned VLAN, the NAS will use the native VLAN of the port as the assigned VLAN, and user authentication will succeed. Otherwise (see the related description below), user authentication will fail.
 - No: If the NAS identifies the assigned VLAN attribute as the VLAN ID, it will use the native VLAN of the port, and user authentication will succeed. If the NAS identifies the assigned VLAN attribute as the VLAN name, it will fail to find the corresponding VLAN ID, causing authentication failure.
- If MAC VLAN is disabled on a Hybrid port, check whether any assigned VLAN is configured on the switch:
 - Yes: If the Hybrid port can redirect to the assigned VLAN or the assigned VLAN does not exist in the tagged VLAN list of the Hybrid port, the NAS will allow the assigned VLAN to pass through the Hybrid port without carrying any tags and uses the native VLAN as the assigned VLAN, and user authentication will succeed. Otherwise (see the related description below), user authentication will fail.
 - No: If the NAS identifies the assigned VLAN attribute as the VLAN ID, it will create a VLAN, allow the VLAN to pass through the Hybrid port without carrying any tags, and use the native VLAN as the assigned VLAN, and user authentication will succeed. If the NAS identifies the assigned VLAN attribute as the VLAN name, it will fail to find the corresponding VLAN ID, causing authentication failure.
- If MAC VLAN is enabled on a Hybrid port, VLAN assignment is as follows:
 - If the VLAN assigned by the authentication server does not exist on the NAS (MAC VLAN requires VLANs to have static

configurations), or has been added to the Hybrid port with tags, or is not supported by MAC VLAN (see the *Configuring MAC VLAN*), user authentication will fail. Otherwise, the NAS will dynamically create MAC VLAN entries based on the assigned VLAN and the MAC addresses of users, and user authentication will succeed. When users go offline, MAC VLAN entries will be dynamically removed.

- If MAC VLAN is disabled on a port, VLAN assignment changes only the native VLAN but not the **native vlan** command configurations of the port. The assigned VLAN takes priority over the VLAN configured in related commands. That is, the native VLAN effective after authentication acts as the assigned VLAN while the native VLAN configured in related commands takes effect only when users go offline.
- If MAC VLAN is enabled on a port and user authentication is based on the MAC address, VLAN assignment dynamically creates MAC VLAN entries without changing the native VLAN of the port.
- No matter MAC VLAN is enabled or not on a Hybrid port, if the assigned VLAN is added to the port with tags, VLAN assignment fails.
- If MAC VLAN is enabled on a port (see the *Configuring MAC VLAN*), VLAN assignment creates an MAC VLAN entry with an all-F mask. If the MAC address of an 802.1X user is overwritten by the MAC address specified by the new MAC VLAN entry, the assigned VLAN must be the same as the VLAN specified by the new MAC VLAN entry. Otherwise, errors will occur to 802.1X users in VLAN assignment. Errors are as follows (including but not limited to): User authentication succeeds but subsequent valid data packets are discarded, causing network access failure. When a user goes offline by sending an EAPOL-LOGOFF packet, the 802.1X authentication entry remains on the NAS and the user status on the authentication server is still online.

Configuration Steps

✚ Enabling Dynamic VLAN Assignment on a Port

- (Optional) After dynamic VLAN assignment is enabled on a port, authenticated users on this port will enter the assigned VLAN.
- Enable dynamic VLAN assignment after 802.1X authentication is enabled on the NAS.

Command	dot1x dynamic-vlan enable
Parameter	N/A
Description	
Defaults	Dynamic VLAN assignment is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when authenticated users should be added to the VLAN assigned by the authentication server.

Verification

- Run the **show dot1x summary** command to display the VLAN of a user and the **show dot1x user id** command to display the VLAN assigned by the RADIUS server.
- Users with VLANs assigned can access the network in the assigned VLANs.

Configuration Example

Enabling Dynamic VLAN Assignment on a Port

<p>Scenario Figure 4-12</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters and enable VLAN delivery on the NAS. ● Enable 802.1X authentication on ports of the NAS. ● Enable dynamic VLAN assignment on a controlled port. <p>NAS configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>
	<pre>Nodexon# configure terminal Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1 Nodexon (config-if)# dot1x port-control auto</pre>
	<pre>Nodexon (config-if)# dot1x dynamic-vlan enable</pre>
<p>Verification</p>	<p>Check whether authentication is proper, network access behaviors change after authentication, and dynamic users can access the network.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username:tests-user,password:test. ● The user fails to ping 192.168.32.120 before authentication. ● After the user enters account information and click Authenticate on Nodexon Supplicant, the authentication succeeds and the user can successfully ping 192.168.32.120. ● After passing authentication, dynamic users can successfully ping 192.168.32.120. ● Information of the authenticated user is displayed, showing that the user jumps from VLAN 2 to VLAN 3. <pre>Nodexon# show dot1x summary</pre>

ID	Username	MAC	Interface	VLAN	Auth-State	Backend-State
Port-Status	User-Type	Time				
16778217	ts-user	0023.aaaa.4286	Fa0/1	3	Authenticated	Idle
static	0days	2h17m29s				Authed

Common Errors

- RADIUS attributes for VLAN assignment are incorrectly configured on the authentication server.
- RADIUS attribute support for VLAN assignment is disabled on the NAS.
- When MAC VLAN is enabled on a Hybrid port for dynamic VLAN assignment, the assigned VLAN has tags.

4.4.9 Configuring the Guest VLAN

Configuration Effect

- If no 802.1X authentication client is available on a controlled port, add the port to the guest VLAN so that users without any authentication clients can temporarily access the network in the guest VLAN.
- If the NAS receives an EAPOL packet after adding a port to a guest VLAN, it regards that this port has an 802.1X authentication client. Then this port is forced out of the guest VLAN to perform 802.1X authentication.

Notes

- A controlled port has no 802.1X authentication client if any one of the following conditions is met:
 1. The port sends three consecutive active authentication packets but does not receive any EAPOL replies within the specified period (**auto-req req-interval** x 3).
 2. The port does not receive any EAPOL replies within 90 seconds.
 3. MAB fails.
- 802.1X-based dynamic VLAN assignment must be enabled for a port.
- When the port status switches from up to down, the port exits from the guest VLAN. When the port status switches from down to up, the NAS re-checks whether to add this port to the guest VLAN.
- If failing to receive eapol packets after 90s, an interface enters the guest VLAN. Because of the increment mechanism of sending shcp discover packets, it may take a long time for a downlink terminal to initiate a dhcp request again. Therefore, the interface cannot obtain the ip address promptly.

Configuration Steps

📌 Configuring the Guest VLAN

- (Optional) After the guest VLAN is configured on a port, check whether the port has 802.1X authentication clients. If no, add the port to the guest VLAN.
- Configure the guest VLAN after 802.1X authentication is enabled on the NAS.

Command	dot1x guest-vlan vid
Parameter	<i>vid</i> : Indicates the guest VLAN to join.
Description	
Defaults	The guest VLAN is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when a user connects to an 802.1X controlled port but has no authentication client. When guest VLAN is enabled on a port, do not configure Layer-2 attributes, and specially do not manually set the VLAN of the port.

Verification

- After a port switches to the guest VLAN, users connected to the port can communicate only in the guest VLAN.
- If a user connected to a port in the guest VLAN installs an 802.1X authentication client and initiates authentication, the port will exit the guest VLAN.

Configuration Example

Configuring Dynamic VLAN Assignment and Guest VLAN

<p>Scenario Figure 4-13</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable 802.1X authentication on ports of the NAS. ● Enable dynamic VLAN assignment on a controlled port. ● Configure the guest VLAN on a controlled port. <p>NAS configurations are as follows:</p>
	<pre>Nodexon (config)# interface FastEthernet 0/1 Nodexon (config-if)# dot1x port-control auto Nodexon (config-if)# dot1x dynamic-vlan enable Nodexon (config-if)# dot1x guest-vlan</pre>
	<p>3</p>
<p>Verification</p>	<p>Check whether network access behaviors change after a port joins a guest VLAN.</p> <ul style="list-style-type: none"> ● Users cannot communicate before the port joins the guest VLAN while can communicate after that.

The NAS prints the log as follows:

```
%DOT1X-5-TRANS_DEFAULT_TO_GUEST: Transformed interface Fa0/1 from default-vlan 1 to
guest-vlan 3 OK.
```

Common Errors

- A port receives an EAPOL packet, causing its failure to join the guest VLAN.

4.4.10 Configuring the Failed VLAN

Configuration Effect

- Configure the failed VLAN on an 802.1X controlled port. If a user fails authentication after failed VLAN is enabled, the port can be added to a failed VLAN so that the user can still access the network.
- Configure the maximum number of consecutive authentication failures. If this number is exceeded, the NAS adds the port to a failed VLAN.

Notes

- If the failed VLAN configured does not exist, a failed VLAN will be dynamically created when a port enters the failed VLAN and automatically removed when the port exits the failed VLAN.
- 802.1X-based dynamic VLAN assignment must be enabled for a port.
- If a port goes down, the port will automatically exit the failed VLAN.
- The failed VLAN and guest VLAN can be configured to the same VLAN.
- In port-based control mode, after a controlled port enters a failed VLAN, only users failing authentication can re-initiate authentication and other users' authentication requests will be discarded. This restriction does not exist in MAC-based control mode.
- Failed VLAN does not support private VLANs. That is, private VLANs cannot be configured as 802.1X failed VLANs.
- If GSN address binding is enabled on a port, users in a failed VLAN cannot access the network.

Configuration Steps

↳ Configuring the Failed VLAN

- (Optional) If the failed VLAN is configured, the NAS adds users rejected by the authentication server to a failed VLAN.
- Configure the failed VLAN after 802.1X authentication is enabled on the NAS.

Command	<code>dot1x auth-fail vlan vid</code>
Parameter	<i>vid</i> : Indicates the failed VLAN to join.
Description	
Defaults	Failed VLAN is disabled by default.
Command Mode	Interface configuration mode

Usage Guide	Configure this command if users need to access the network even after authentication fails.
--------------------	---

▾ **Configuring the Maximum Number of Failed VLAN Attempts**

- (Optional) Configure the maximum number of times when a user is rejected by the authentication server. If this number is exceeded, the port can be added to a failed VLAN.
- Configure the maximum number of failed VLAN attempts after 802.1X authentication is enabled on the NAS.

Command	<code>dot1x auth-fail max-attempt value</code>
Parameter Description	<i>value</i> : Indicates the maximum number of times when a user fails authentication.
Defaults	The default value is 3.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when the maximum number of failed VLAN attempts needs to be adjusted.

Verification

- When a port switches to a failed VLAN, users connected to the port can communicate only in the failed VLAN.

Configuration Example

▾ **Configuring the Failed VLAN**

<p>Scenario Figure 4-14</p>	<p>The diagram illustrates a network setup for 802.1X authentication. A central Switch is connected to a Hub on its left and a Radius Server on its right. The Hub has two ports connected to a laptop (IP 192.168.217.83) and a server (IP 192.168.217.82). The Switch's F0/1 port is connected to the Hub. The Switch's F0/23 port is connected to the Radius Server (IP 192.168.32.120). The Switch's F0/24 port is connected to the Internet (IP 192.168.217.81).</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable 802.1X authentication on ports of the NAS. ● Enable port-based authentication on a controlled port. <p>NAS configurations are as follows. For detailed configuration on the RADIUS server, see the <i>Configuring RADIUS</i>.</p>

	<pre>Nodexon# configure terminal Nodexon (config)# aaa new-model Nodexon (config)# radius-server host 192.168.32.120 Nodexon (config)# radius-server key Nodexon Nodexon (config)# interface FastEthernet 0/1 Nodexon (config-if)# dot1x port-control auto</pre>
	<pre>Nodexon (config-if)# dot1x auth-fail vlan 3</pre>
<p>Verification</p>	<p>Check whether authentication is proper, network access behaviors change after authentication, and dynamic users can access the network.</p> <ul style="list-style-type: none"> ● The account is successfully created, such as username:tests-user,password:test. ● The user fails to ping 192.168.32.120 before authentication. ● Start Nodexon Supplicant, enter incorrect account information, and click Authenticate. The authentication fails, the user can successfully ping the IP address of a failed VLAN. ● Information of the authenticated user is displayed. <pre>Nodexon(config)#show dot1x user name ts-user Supplicant information: MAC address b048.7a7f.f9f3 Username ts-user User ID 16777303 Type static VLAN 1 Port wlan 1 Online duration 0days 0h 0m21s Up average bandwidth 0 kBps Down average bandwidth 0 kBps Authorized VLAN 1 Authorized session time 20736000 seconds Authorized flux unlimited Accounting No Proxy user Permit Dial user Permit IP privilege 0 Private supplicant no Authorized by Auth-Fail-Vlan 3 Max user number on this port 0</pre>

Common Errors

- If a user fails authentication not due to rejection of the authentication server, for example, due to installation failure as a result of hardware resource insufficiency, it cannot enter the failed VLAN.

4.4.11 Configuring Extended Functions

Configuration Effect

- Some users use authentication clients embedded in the operating system. These clients may not initiate authentication immediately after the users access the network, affecting user experience on network access. Enable active authentication to so that such users can initiate authentication immediately after accessing the network.
- Active authentication means that the NAS sends a request/id packet to trigger Nodexon Supplicant to perform 802.1 authentication. Therefore, you can use this function to detect whether Nodexon Supplicant is used. For example, this function is required for MAB deployment.
- Configure the authenticable host list to specify users that can be authenticated on the port, which restricts physical access points of users to enhance network security
- The multi-account function allows a user to switch its account upon re-authentication. In special scenarios such as Windows domain authentication, multiple authentications are required to access the domain and the user account changes during authentication. This function applies to these scenarios.
- By default, the NAS uses its own MAC address as the source MAC address of EAP packets during 802.1X authentication. Some versions of Nodexon supplicants check whether the access switch is a Nodexon switch based on the MAC address of EAP packets and implement some private features. When performing 802.1X authentication with these supplicants, you can enable the virtual source MAC address to use related private features.
- 802.1X allows users to obtain IP addresses before accounting. In this manner, the IP address is carried during user accounting, meeting service requirements. After a user is authenticated and goes online, the NAS can obtain the IP address of the user from the supplicant or through DHCP snooping, and then 802.1X server initiates an accounting request. To avoid the case in which the NAS does not initiate accounting for a long time due to failure to obtain the IP address of the authentication client, configure the IP detection timeout for this function. If the NAS does not obtain the IP address of the user within the configured time (5 minutes by default), it forces the user offline.
- If 802.1X authentication and MAB are enabled, you can specify the priorities of 802.1X authentication and MAB on the same port. By default, the one triggered first should be first performed and 802.1X authentication takes priority over MAB. That is, if the NAS receives an EAPOL packet from a user after the user performs MAB, the original MAB user goes offline and performs 802.1X authentication. At present, you can configure each user to first perform 802.1X authentication. If a user performs MAB following the 802.1X authentication failure and MAB takes priority over 802.1X authentication, the user can ignore 802.1X authentication after passing MAB.
- Based on a real scenario, H3C devices are deployed and the MAB authentication server configures the user name in xx-xx-xx-xx-xx-xx format. However, the default MAB authentication user name format of Nodexon devices is xxxxxxxxxxxx.
- Therefore, a command needs to be added to control the user name format.
The multi-account function must be disabled if accounting is enabled. Otherwise, accounting may be inaccurate.

Notes MAB requires active authentication. Therefore, active authentication must be enabled if MAB is enabled.

- IP-based accounting is not required in two situations:
 - IPv4 addresses and Nodexon Supplicant are deployed. This function is not required because Nodexon Supplicant can upload the IPv4 addresses of users.
 - Static IP addresses are deployed.

Configuration Steps

▾ Enabling Active Authentication

- (Optional) If active authentication is enabled, the controlled port sends an authentication request actively after configuration. After receiving this request, the authentication client initiates 802.1X authentication.
- Enable active authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req
Parameter Description	N/A
Defaults	Apart from on N1800K switches, active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The destination addresses of active authentication packets are the multicast address. If the connected clients may not initiate authentication automatically, configure this command to make the NAS actively initiate authentication. When controlled ports are Trunk ports, enable active authentication so that authentication requests can be sent based on each VLAN of trunk ports.

▾ Configuring the Number of Active Authentication Requests

- (Optional) Configure the number of active authentication requests sent by the NAS.
- Configure the number of active authentication requests after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req packet-num num
Parameter Description	<i>num</i> : Indicates the number of active authentication requests.
Defaults	The number of active authentication request is not configured by default.
Command Mode	Global configuration mode
Usage Guide	If active authentication is enabled, configure this command to restrict the number of active authentication packets sent by a port and thereby avoid sending excessive packets.

▾ Enabling User Detection for Active Authentication

- (Optional) Configure the NAS not to send authentication requests actively if there are authenticated users on a controlled port.
- Enable user detection for active authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req user-detect
Parameter	N/A
Description	
Defaults	User detection for active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	After this command is configured, the NAS does not send authentication packets actively if there are authenticated users on controlled Access ports. On Trunk ports, the NAS checks for authenticated users based each VLAN. If there are authenticated users on a VLAN, the NAS does not send authentication packets automatically.

↘ Configuring the Interval of Active Authentication Request

- (Optional) Configure the interval at which the NAS sends an authentication request actively.
- Enable the interval of active authentication request after 802.1X authentication is enabled on the NAS.

Command	dot1x auto-req req-interval time
Parameter Description	<i>Time</i> : Indicates the interval of active authentication request.
Defaults	The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring the Authenticatable Client List

- (Optional) Configure the authenticatable client list on a controlled port. Only clients on the list can perform 802.1X authentication.
- Configure the authenticatable client list after 802.1X authentication is enabled on the NAS.

Command	dot1x auth-address-table address mac-addr interface interface
Parameter Description	<i>mac-addr</i> : Indicates the MAC address of the access user. <i>interface</i> : Indicates the port of the access user.
Defaults	All users can perform authentication.
Command Mode	Global configuration mode
Usage Guide	Configure this command when specified users should be able to perform authentication on a controlled port.

↘ Enabling 802.1X Packets Sending with the Pseudo Source MAC Address

- (Optional) Configure the **dot1x pseudo source-mac** command when Nodexon Supplicant fails to identify the NAS as a Nodexon device based on the MAC address of the NAS.
- Configure the pseudo MAC address as the source MAC address for 802.1X authentication after 802.1X authentication is enabled on the NAS.

Command	dot1x pseudo source-mac
Parameter Description	N/A
Defaults	User detection for active authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	Configure this command when Nodexon Supplicants cannot identify the NAS as a Nodexon device based on the source MAC address in the EAPOL packet sent by the NAS or implement private attributes during authentication. If this command is configured, the EAPOL packet sent by the NAS uses 00-1A-A9-17-FF-FF as the source MAC address so that these Nodexon Supplicants can

identify the NAS as a Nodexon device.

↘ **Enabling Multi-account Authentication with One MAC Address**

- (Optional) Run the **dot1x multi-account enable** command to allow the same MAC address to be used by multiple accounts.
- Enable multi-account authentication with one MAC address after 802.1X authentication is enabled on the NAS.

Command	dot1x multi-account enable
Parameter Description	N/A
Defaults	Multi-account authentication is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Configure this command when multi-account authentication is required in 802.1X authentication, e.g. in the case of Windows domain authentication. In this case, the authentication client can directly use a new account to initiate authentication while the previous account is still online. Multi-account authentication is disabled by default.

↘ **Configuring the Maximum Number of Authenticated Users on a Port**

- (Optional) You can restrict the number of online users on a controlled port, including static users and dynamic users.
- Configure the maximum number of authenticated users on a port after 802.1X authentication is enabled on the NAS.

Command	dot1x default-user-limit <i>num</i>
Parameter Description	<i>num</i> : Indicates the maximum number of online users.
Defaults	There is no restriction on the number of users on a port by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when there is a need to restrict the number of authenticated users on a port.

↘ **Enabling IP-triggered Accounting**

- (Optional) If IP-triggered accounting is enabled, the NAS sends an accounting request to the authentication server after obtaining the IP address of the user.

- Enable IP-triggered accounting after 802.1X authentication is enabled on the NAS.

Command	dot1x valid-ip-acct enable
Parameter Description	N/A
Defaults	IP-triggered accounting is disabled by default.
Command Mode	Global configuration mode
Usage Guide	If both accounting and IP-triggered accounting are enabled, the NAS initiates accounting only after obtaining the IP address of the authentication client, and forces the user offline if it fails to obtain the IP address. If accounting is disabled but IP-triggered accounting is enabled, the NAS does not initiate accounting after obtaining the IP address of the authentication client, and forces the user offline if it fails to obtain the IP address within the timeout.

▾ Configuring the Timeout of Obtaining IP Addresses After Authentication

- (Optional) Configure the timeout of obtaining IP addresses if IP-triggered accounting is enabled.
- Configure the IP address obtaining timeout after 802.1X authentication is enabled on the NAS.

Command	dot1x valid-ip-acct timeout <i>time</i>
Parameter Description	<i>time</i> : Indicates the timeout in the unit of minutes.
Defaults	The default value is 5 minutes.
Command Mode	Global configuration mode
Usage Guide	It is recommended to use the default value. Configure this command when there is a need to change the IP address obtaining timeout after users pass authentication.

▾ Enabling 802.1X Precedence over MAB

- (Optional) If 802.1X precedence over MAB is enabled, a user first performs 802.1X authentication. If 802.1X authentication fails, the user initiates MAB and MAB takes priority of 802.1 authentication.
- 802.1X authentication and MAB must be enabled on a port.

Command	dot1x auth-with-order
Parameter Description	N/A
Defaults	802.1X precedence over MAB is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	Configure this command when a user needs to first perform 802.1X authentication and initiate MAB if 802.1X authentication fails, and MAB takes priority of 802.1 authentication.

▾ Configuring the Compatibility Function for H3C 802.1X Authentication Clients and Authentication Servers

- (Optional) This function is effective to 802.1X-authenticated and MAB-authenticated users.

Command	dot1x user-name compatible
Parameter Description	-
Defaults	This function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Enable this function when the H3C authentication client and authentication server are used for 802.1X authentication or the H3C authentication server is used for MAB authentication.

↳ Disabling Global 802.1X

- (Optional) This function is effective to both 802.1x and MAB-authenticated users.

Command	dot1x system disable
Parameter Description	-
Defaults	By default, global 802.1x is enabled.
Command Mode	Global configuration mode
Usage Guide	When the server is unreachable, disable global 802.1x, so users can access the Internet without authentication. After the server resumes reachability, enable global 802.1x, and users have to pass authentication before accessing the Internet.

4.5 Monitoring

Clearing

-  Authentication user information can be cleared after 802.1X is disabled.

Description	Command
Clears 802.1X user information.	no do1x port-control auto
Clears 802.1X user information.	clear dot1x user
Restores the default 802.1X configuration.	dot1x default

Notes

- The **dot1x default** command is used to restore global configurations.

Description	Command
-------------	---------

Restore the default value of status machine timeout duration.	dot1x timeout quiet-period dot1x timeout server-timeout dot1x timeout supp-timeout dot1x timeout tx-period
Restore default values of configurations related to re-authentication.	dot1x re-authentication dot1x timeout re-authperiod dot1x reauth-max
Restore default values of configurations related to proactive requests.	dot1x auto-req dot1x auto-req user-detect dot1x auto-req req-interval dot1x auto-req packet-num
Restores the default value of the number of retransmission times.	dot1x mac-req
Restores the default value of the authentication mode.	dot1x auth-mode
Restore the default values of configurations related to client probing.	dot1x client-probe enable dot1x probe-timer alive dot1x probe-timer interval
Restores the default value of the function of supporting only the private client.	dot1x private-supplicant-only
Restores the default value of the pseudo source MAC address function.	dot1x pseudo source-mac
Restores the default value of the number of VLAN redirection times upon authentication failures.	dot1x auth-fail max-attempt
Restores the default value of the function of one MAC address for multiple accounts.	dot1x multiaccount enable
Restores the default value of the dot1x redirection function.	dot1x redirect
Restores the default value of the silent timeout duration.	dot1x multi-mab quiet-period
Restore the default values of functions related to accounting after obtaining the IP address.	dot1x valid-ip-acct enable dot1x valid-ip-acct timeout

Displaying

Description	Command
-------------	---------

 System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs AAA. (For details, see the <i>Configuring AAA</i> .)	debug aaa
Debugs RADIUS. (For details, see the <i>Configuring RADIUS</i> .)	debug radius
Debugs 802.1X events.	debug dot1x event
Debugs 802.1X packets.	debug dot1x packet
Debugs 802.1X state machine (STM).	debug dot1x stm
Debugs 802.1X internal communication.	debug dot1x com
Debugs 802.1X errors.	debug dot1x error

5 Configuring Web Authentication

5.1 Overview

5.1.1 Web Authentication

Web authentication controls user access to networks. It requires no authentication software on clients. Instead, users can perform authentication on common browsers.

When unauthenticated clients attempt to access the Internet using browsers, the network access server (NAS) forcibly redirects the browsers to a specified site pointing to a Web authentication server, also called a portal server. Users can access the services on the portal server before being authenticated, such as downloading security patches and reading notices. If a user wants to access network resources beyond the portal server, the user must get authenticated by the portal server through a browser.

Besides providing convenient authentication, the portal server performs Webpage interaction with browsers, providing personalized services, such as advertisements, notices, and business links on the authentication page.

Nodexon

WebAuthentication Versions

There are three versions of Nodexon Web authentication, including Nodexon First-Generation Web Authentication, Nodexon Second-Generation Web Authentication, and Nodexon Internal Portal (iPortal) Web Authentication. The Web authentication

process varies with authentication versions. For details, see Section 5.3 "Features".

 The three versions of Web authentication are highly divergent in features and configurations. It is recommended to read through the relevant chapters carefully before configuration.

 Both Nodexon Second-Generation Web Authentication and Nodexon iPortal Web Authentication support local account authentication on the NAS. Because Remote Authentication Dial In User Service (RADIUS) authentication is more

 commonly used in reality, it is used as an example in the chapter "Applications".

The concept of "interface" varies with product types. For example, the interfaces on a layer-2 switch are physical ports. This document uses the unified term "interface" to include them. In application, recognize the real meaning based on specific products and functions.

 Web authentication supports user online traffic detection. For details, see the Configuring SCC.

 Web authentication supports the authentication of domain names. That is, accounts can be authenticated in the format of user name@domain name. This requires enabling the domain-name-based authentication, authorization and accounting (AAA) service. For details, see the Configuring AAA.

Protocols and Standards

- HTTP: RFC1945 and RFC2068

- HTTPS: RFC2818
- SNMP: RFC1157 and RFC 2578
- RADIUS: RFC2865, RFC2866, and RFC3576

5.2 Applications

Application	Description
Basic Scenario of Web Authentication	Basic layer-2 authentication scenario, where a NAS, portal server, and RADIUS server constitute an authentication system which connects a client with the NAS through the layer-2 network.

5.2.1 Basic Scenario of Web Authentication

Scenario

See Figure 5-1.

- Deploy a Web authentication scheme on the NAS.
- The client connected to the NAS needs to pass Web authentication before accessing the Internet.

Figure 5-1 Networking Topology of Web Authentication

Remarks	<p>Web authentication is applicable to both layer-2 and layer-3 networks. At layer 3, the source MAC address and VID of a packet are changed after it is routed, but the source IP address remains the same as the only identifier of a client. Therefore, the binding policy of Web authentication on layer-3 devices must adopt the IP-only binding mode. Here, layer-2 NAS is used as an example.</p> <p>NX-SAM program is installed on the RADIUS server. NX-ePortal program is installed on the portal server.</p>
----------------	---

Deployment

- Enable Web authentication on the client-accessed interface or globally on the NAS.
- Configure the ePortal server and the communication key on the NAS (for only Nodexon First-Generation and Second-Generation Web Authentication).

- Configure the Simple Network Management Protocol (SNMP) communication parameters of the ePortal server on the NAS (for only Nodexon First-Generation and Second-Generation Web Authentication).
- Configure the consistent communication parameters on the ePortal server and SAM server (for only Nodexon First-Generation Web Authentication).
- Create user accounts on the SAM server.
- Configure AAA and method lists on the NAS (for only Nodexon Second-Generation and iPortal Web Authentication).
- Configure the IP address of the SAM server on the NAS (for only Nodexon Second-Generation and iPortal Web Authentication).
- Configure the names of the Web authentication method lists on the NAS (for only Nodexon Second-Generation and iPortal Web Authentication).

5.3 Features

Basic Concepts

📌 Nodexon First-Generation Web Authentication

Nodexon First-Generation Web Authentication should cooperate with the NX-ePortal software. The server installed with NX-ePortal provides a login page to submit user authentication information, and initiates an authentication request to the RADIUS server directly. After authentication succeeds, the NAS gets user information delivered through the SNMP protocol, and thereby controls user access permissions. Communication during Web authentication of this version depends on private SNMP nodes. Moreover, the ePortal server takes the place of the NAS in authentication and accounting, which relieves the NAS from service burden.

📌 Nodexon Second-Generation Web Authentication

Nodexon Second-Generation Web Authentication complies with the *CMCC WLAN Service Portal Specification*. The portal server is responsible only for Webpage interaction with users. The NAS interacts with the RADIUS server to implement authentication. The interaction between the portal server and the NAS complies with the *CMCC WLAN Service Portal Specification*. The portal server provides a login page for users to submit their information, and informs the NAS of user information through the portal protocols. The NAS completes authentication by interacting with the RADIUS server based on the user information, assigns access permissions to authenticated clients, and returns authentication results to the portal server.

The implementation process of Nodexon Second-Generation Web Authentication is mainly completed on the NAS. This raises a higher demand on the NAS's capability to handle heavy tasks. Meanwhile, the portal server is simplified. The standard *CMCC WLAN Service Portal Specification*, which gains highly industry support, enables various vendors to develop compatible products.

📌 Version Comparison

Authentication roles:

-
- Client: Its functions are the same among the three types of Web authentication.

- **NAS:** In Nodexon First-Generation Web Authentication, the NAS implements only URL redirection and exchanges user login/logout notifications with the portal server. In Nodexon Second-Generation Web Authentication, the NAS is responsible for redirecting and authenticating users as well as notifying the portal server of authentication results.
- **Portal server:** In Nodexon First-Generation Web Authentication, the portal server is responsible for interaction with clients through Webpages, authenticating users, and notifying the NAS of authentication results. In Nodexon Second-Generation Web Authentication, the portal server is responsible for interacting with clients through Webpages, notifying the NAS of users' authentication information, and receiving authentication results from the NAS.
- **RADIUS server:** Its functions are the same among the three types of Web authentication.

Authentication process:

- In Nodexon Second-Generation Web Authentication, the authentication and accounting functions are transferred from the portal server to the NAS.
- Because authentication proceeds on the NAS, the second-generation NAS does not need to wait for the authentication results notified by the portal server as the first generation.

Logout process:

- In Nodexon First-Generation Web Authentication, a logout action may be triggered by a notification from the portal server, or traffic detection or port status detection performed by the NAS. In Nodexon Second-Generation Web Authentication, a logout action may be triggered by a notification from the portal server, a kickout notification from the RADIUS server, or traffic detection or port status detection performed by the NAS.

i The selection of the Web authentication versions depends on the type of the portal server in use. In Nodexon First-Generation Web Authentication, Accounting Stop packets are sent by the portal server. In Nodexon Second-Generation Web Authentication, Accounting Stop packets are sent by the NAS.

i Command parameters in this document may be shared by the three Web authentication versions, or not. Read through this document carefully to avoid parameter misconfiguration that will affect Web authentication.

Overview

Feature	Description
Nodexon First-Generation Web Authentication	The portal server is deployed and supports only Nodexon First-Generation Web Authentication.
Nodexon Second-Generation Web Authentication	The portal server is deployed and complies with the <i>CMCC WLAN Service Portal Specification</i> .

5.3.1 Nodexon First-Generation Web Authentication

HTTP Interception

HTTP interception means the NAS intercepts to-be-forwarded HTTP packets. Such HTTP packets are initiated by the browsers of the clients connected to the NAS, but they are not destined for the NAS. For example, when a client attempts to visit the website www.google.com using the Internet Explorer, the NAS is expected to forward the HTTP request packets to the gateway. If HTTP interception is enabled, these packets will not be forwarded.

After HTTP interception is successful, the NAS redirects the HTTP requests from the client to itself to establish a session between them. Then, the NAS pushes a Webpage to the client through HTTP redirection, which can be used for authentication, software downloading or other purposes.

You can specify the clients and destination interfaces to enable or disable HTTP interception for Web authentication. In general, HTTP requests from unauthenticated clients will be intercepted, and those from authenticated clients will not. HTTP interception is the foundation of Web authentication. Web authentication is automatically triggered once HTTP interception succeeds.

HTTP Redirection

According to HTTP protocols, after the NAS receives a HTTP GET or HEAD request packet from a client, a packet with 200 (Ok) status code is replied if it is able to provide the required resources, or a packet with 302 (Moved Temporarily) status code is returned if unable. Another URL is provided in the 302 packet. After receiving the packet, the client may resend a HTTP GET or HEAD request packet to the new URL for requesting resources. This process is called redirection.

HTTP redirection is an important procedure following HTTP interception in Web authentication. It takes the advantage of 302 status code defined in HTTP protocols. HTTP interception creates a session between the NAS and a client. The client sends HTTP GET or HEAD request packets (which should have been sent to another site) to the NAS. The NAS responds with a 302 packet with a specific redirection page. Thereby, the client resends the requests to the redirection page.

Because more and more application programs run HTTP protocols, the use of the 302 redirection packet may divert a large amount of HTTP traffic (not sent by browsers) to the portal server, which will affect network authentication. To address this problem, HTTP redirection technology on the NAS adopts noise reduction to replace the 302 packets with the **js** script.

Working Principle

Figure 5-1 shows the networking topology of Web authentication.

First-generation Webauth roles:

- Authentication client: Is usually a browser running HTTP protocols. It sends HTTP requests for accessing the Internet.
- NAS: Is an access-layer device in a network. The NAS is directly connected to clients and must be enabled with Web authentication.
- Portal server: Provides a Web page for Web authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, sends the information to the RADIUS server for authentication, and notifies the client and NAS of the authentication result. Figure 5-1 shows Nodexon ePortal server.
- RADIUS server: Provides the RADIUS-based authentication service to remote clients. The portal server extracts users' authentication account information from HTTP packets and initiates authentication requests to the RADIUS server through the RADIUS protocol. The RADIUS server returns the authentication result to the portal server through the RADIUS protocol. Figure 5-1 shows the RADIUS server installed with the NX-SAM program.

First-generation Webauth process:

1. Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Thereafter, an authentication page is displayed on the browser.

2. During authentication, the client enters information, for example, username, password, and verification code, on the Webauth URL to interact with the portal server and complete authentication.
3. After the user is authenticated, the portal server notifies the NAS that the client has passed authentication, and the NAS allows the client to access resources on the Internet.

Figure 5-2 shows the flowchart of Nodexon First-Generation Web Authentication by using an AP as the NAS.

Figure 5-2 Flowchart of Nodexon First-Generation Web Authentication

First-generation client logout process:

There are two scenarios of client logout. One scenario is detected by the NAS that a client gets offline for the maximum online time is out, the upper traffic limit is reached, or the link is disconnected. The other scenario is detected by the portal server that a client logs out by clicking the **Logout** button on the logout page or the keep-alive page is invalid.

1. Scenario 1: The NAS detects a client to logout and informs the portal server. Then the portal server deletes the user information on the NAS through SNMP and displays a logout page to the client.

2. Scenario 2: The portal server detects a client to logout and informs the NAS through SNMP and displays a logout page to the client.
3. In the two scenarios, the portal server sends an Accounting Stop request to the RADIUS server and notifies the RADIUS server that the client has logged out.

Related Configuration

↘ **Configuring the First-Generation Webauth Template**

By default, the first-generation Webauth template is not configured.

Run the **web-auth template eportalv1** command in global configuration mode to create the first-generation Webauth template.

The template is used to implement Web authentication.

↘ **Configuring the IP Address of the Portal Server**

By default, the IP address of the portal server is not configured.

Run the **ip {ip-address}** command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

↘ **Configuring the Webauth URL of the Portal Server**

By default, the Webauth URL of the portal server is not configured.

Run the **url {url-string}** command in template configuration mode to configure the Webauth URL of the portal server.

The URL to which clients are redirected is the address of the Webauth URL provided by the portal server.

↘ **Specifying the Webauth Binding Mode**

Run the **bindmode** command in template configuration mode to specify the Webauth binding mode.

In Web authentication on layer-3 networks, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

↘ **Configuring the Webauth Communication Key**

By default, the Webauth communication key is not configured.

Run the **web-auth portal key {string}** command in global configuration mode to configure the Webauth communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

↘ **Enabling Nodexon First-Generation Web Authentication**

By default, Nodexon First-Generation Web Authentication is disabled.

Run the **web-auth enable** command in interface configuration mode to enable Nodexon First-Generation Web Authentication on the client-connected ports.

After Web authentication is enabled, the unauthenticated clients connecting to a port will be redirected to the Webauth URL.

↘ Configuring the SNMP-Server Host

By default, the SNMP-server host and community string are not configured.

Run the **snmp-server host** *{ip-address}* **version 2c** *{community-string}* **web-auth** command in global configuration mode to configure the SNMP-server host and community string for Web authentication.

The SNMP-server host is configured to receive Inform/Trap packets of user logout.

↘ Configuring the SNMP-Server Community String

By default, the SNMP-server community string is not configured.

Run the **snmp-server community** *{community-string}* **rw** command in global configuration mode to configure the SNMP-server community string.

The SNMP-server community string is configured to read/write user information from/to the NAS.

↘ Enabling the SNMP Trap/Inform Function

By default, the SNMP Trap/Inform function is disabled.

Run the **snmp-server enable traps web-auth** command in global configuration mode to enable the SNMP Trap/Inform function.

The SNMP Trap/Inform function is configured to enable the NAS to inform the portal server of user logout.

5.3.2 Nodexon Second-Generation Web Authentication

HTTP Interception

Same as the HTTP interception technology of Nodexon First-Generation Web Authentication.

HTTP Redirection

Same as the HTTP redirection technology of Nodexon First-Generation Web Authentication.

Working Principle

Figure 5-1 shows the networking topology of Web authentication.

Second-generation Webauth roles:

1. Authentication client: Is usually a browser running HTTP protocols. It sends HTTP requests for accessing the Internet.
2. NAS: Is an access-layer device in a network. The NAS is directly connected to clients and must be enabled with Web authentication. The NAS receives user authentication information from the portal server, sends authentication requests to the RADIUS server, determines whether users can access the Internet according to authentication results, and returns the authentication results to the portal server.
3. Portal server: Provides a Web page for Web authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, transfers the information to the NAS, and displays the authentication result returned by the NAS to the user on a page. Figure 5-1 shows Nodexon ePortal server.

4. RADIUS server: Provides the RADIUS-based authentication service to remote clients. Figure 5-1 shows the RADIUS server installed with the NX-SAM program.

Second-generation Webauth process:

1. Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Thereafter, an authentication page is displayed on the browser.
2. During authentication, the client enters information, for example, username, password, and verification code, on the Webauth URL to interact with the portal server.
3. The portal server sends the user authentication information to the NAS.
4. The NAS initiates authentication to the RADIUS server and returns the authentication result to the portal server.
5. The portal server displays the authentication result (success or failure) to the user on a page.

Figure 5-3 Flowchart of Nodexon Second-Generation Web Authentication

Second-generation client logout process:

There are two scenarios of client logout. One scenario is detected by the NAS that a client gets offline for the maximum online time is out, the upper traffic limit is reached, or the link is disconnected. The other scenario is detected by the portal server that a client logs out by clicking the **Logout** button on the logout page or the keep-alive page is invalid.

1. When a user clicks the **Logout** button on the online page, the portal server notifies the NAS to get the user offline.
2. The NAS gets a client offline with traffic lower than the threshold based on the parameters of user online traffic detection.
3. When the RADIUS server plans to force a client offline based on a certain policy, the NAS notifies the portal server to push a logout page to the client.

Related Configuration

↘ **Configuring the Second-Generation Webauth Template**

By default, the second-generation Webauth template is not configured.

Run the **web-auth template{eportalv2 | *template-name* v2}** command in global configuration mode to create a second-generation Webauth template.

The template is used to implement Web authentication.

↘ **Configuring the IP Address of the Portal Server**

By default, the IP address of the portal server is not configured.

Run the **ip { *ip-address* }** command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

↘ **Configuring the Webauth URL of the Portal Server**

By default, the Webauth URL of the portal server is not configured.

Run the **url {*url-string* }** command in template configuration mode to configure the Webauth URL of the portal server.

The URL to which clients are redirected is the address of the Webauth URL provided by the portal server.

↘ **Specifying the Webauth Binding Mode**

Run the **bindmode** command in template configuration mode to specify the Webauth binding mode.

In Web authentication on layer-3 networks, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

↘ **Configuring the Webauth Communication Key**

By default, the Webauth communication key is not configured.

Run the **web-auth portal key { *string* }** command in global configuration mode to configure the Webauth communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

↘ **Enabling Nodexon Second-Generation Web Authentication**

By default, Nodexon Second-Generation Web Authentication is disabled.

Run the **web-auth enable {eportalv2 | template-name v2}** command in interface configuration mode to enable Nodexon Second-Generation Web Authentication on the client-connected ports.

After Web authentication is enabled, the unauthenticated clients connecting to a port will be redirected to the Webauth URL.

↳ Enabling AAA

By default, AAA is disabled.

Run the **aaa new-model** command in global configuration mode to enable AAA.

Nodexon Second-Generation Web Authentication relies on AAA. Enable AAA before you implement the former.

↳ Configuring the RADIUS-Server Host and Communication Key

By default, the RADIUS-server host and communication key are not configured.

Run the **radius-server host** command in global configuration mode to configure the RADIUS-server host and communication key.

The RADIUS-server host is responsible for authenticating users.

↳ Configuring an AAA Method List for Nodexon Second-Generation Web Authentication

By default, no AAA method list is configured for Nodexon Second-Generation Web Authentication.

Run the **aaa authentication web-auth** command in global configuration mode to configure an AAA method list for Nodexon Second-Generation Web Authentication.

The AAA authentication method list is used for interaction during the Webauth process.

↳ Configuring an AAA Method List for Nodexon Second-Generation Web Accounting

By default, no AAA method list is configured for Nodexon Second-Generation Web Accounting.

Run the **aaa accounting network** command in global configuration mode to configure an AAA method list for Nodexon Second-Generation Web Accounting.

The AAA method list for Web accounting is used for accounting interaction during the Webauth process.

↳ Specifying an AAA Method List

The default AAA method list is used if no list is specified.

Run the **authentication** command in template configuration mode to specify an AAA method list.

The AAA method list is specified to send authentication requests to AAA.

↳ Specifying an AAA Accounting Method List

The default AAA accounting method list is used if no list is specified.

Run the **accounting** command in template configuration mode to specify an AAA accounting method list.

The AAA accounting method list is specified to send accounting requests to AAA.

Configuration	Description and Command	
Webauth Logging	web-auth logging enable { num }	Configures the rate limit Webauth logging.
Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients	 (Optional) It is used to adjust the HTTP session limit. The limit value needs to be increased when there are many sessions in the background.	
	http redirect session-limit { session-num } [port { port-session-num }]	Configures the maximum number of HTTP sessions for unauthenticated clients.
Configuring the HTTP Redirection Timeout	 (Optional) It is used to modify the timeout period for redirection connections. The timeout needs to be increased to complete redirection when the network condition is bad.	
	http redirect timeout { seconds }	Configures the HTTP redirection timeout.
Configuring the Straight-Through ARP Resource Range	 (Optional) It is used to permit the ARP of the specified addresses to pass. The gateway ARP must be permitted to pass when ARP check is enabled.	
	http redirect direct-arp { ip-address [ip-mask] }	Configures the straight-through ARP resource.
Configuring an Authentication-Exempted Address Range	 (Optional) It is used to exempt clients from authentication when accessing the Internet.	
	web-auth direct-host { ip-address [ip-mask] [arp] } [port interface-name mac-address }	Configures the range of the IP or MAC addresses of clients free from authentication.
Configuring the Interval for Updating Online User Information	 (Optional) It is used to configure the interval for updating online user information.	
	web-auth update-interval { seconds }	Configures the interval for updating online user information.
Configuring Portal Detection	 (Optional) It is used to detect the availability of the portal server. If it is not available, the services are switched to the standby portal server. This function must be used together with portal standby function.	
	web-auth portal-check [interval intsec [timeout tosec] [retransmit retries]	Configures the portal server detection interval, timeout period, and timeout retransmission times.
Configuring Portal Escape	 (Optional) It is used to allow new clients to access the Internet without authentication when the portal server is not available.	
	web-auth portal-escape	Configures portal escape.
Enabling DHCP Address Check	 (Optional) It is used to check whether the IP address of a client is allocated by the DHCP server. If not, the client's authentication request is denied.	
	web-auth dhcp-check	Checks whether the IP address of a client is assigned by the DHCP server.

Configuration	Description and Command		
Configuring a Whitelist and Blacklist	<p> (Optional) It is used to configure a blacklist to prevent authenticated clients from accessing some network resources, and a whitelist to allow unauthenticated clients to access some network resources.</p> <table border="1"> <tr> <td>web-auth acl{black-ip ip black-port port black-url name white-url name}</td> <td>Configures a whitelist and blacklist.</td> </tr> </table>	web-auth acl {black-ip ip black-port port black-url name white-url name}	Configures a whitelist and blacklist.
web-auth acl {black-ip ip black-port port black-url name white-url name}	Configures a whitelist and blacklist.		
Configuring the Portal Communication Port	<p> (Optional) It is used to configure the port (source port) used for the communication between the NAS and portal server.</p> <table border="1"> <tr> <td>ip portal source-interface interface-type interface-num</td> <td>Specifies the port used for the communication between the NAS and portal server.</td> </tr> </table>	ip portal source-interface interface-type interface-num	Specifies the port used for the communication between the NAS and portal server.
ip portal source-interface interface-type interface-num	Specifies the port used for the communication between the NAS and portal server.		
Configuring VLAN-Based Authentication on a Port	<p> (Optional) It is used to configure the VLAN in which only the STAs inside the configured VLAN cannot initiate Web authentication.</p> <table border="1"> <tr> <td>web-auth vlan-control vlan-list</td> <td>Configures the VLAN-based authentication on a port.</td> </tr> </table>	web-auth vlan-control vlan-list	Configures the VLAN-based authentication on a port.
web-auth vlan-control vlan-list	Configures the VLAN-based authentication on a port.		
Disabling ARP Detection	<p> (Optional) It is used to disable ARP detection. After the function is disabled, it is not detected that the IP address or MAC address of a client migrates.</p> <table border="1"> <tr> <td>no web-auth station-move arp-detect</td> <td>Disables ARP detection.</td> </tr> </table>	no web-auth station-move arp-detect	Disables ARP detection.
no web-auth station-move arp-detect	Disables ARP detection.		

5.4.1 Configuring Nodexon First-Generation Web Authentication

Configuration Effect

Redirect unauthenticated clients to the Webauth URL to perform authentication.

Notes

N/A

Configuration Steps

➤ Configuring the Portal Server

- (Mandatory) To enable Web authentication successfully, you must configure and apply the portal server.
- When the NAS or convergence device finds an unauthenticated client attempting to access network resources through HTTP, it redirects the access request to the specified Webauth URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, unauthenticated clients can directly visit this IP address through HTTP.

➤ Configuring the Communication Key Between the NAS and Portal Server

- (Mandatory) To enable Web authentication successfully, you must configure the key used for the communication between the NAS or convergence device and portal server.
- When the NAS finds an unauthenticated client attempting to access network resources, it redirects the client to the specified Webauth URL, where the client can initiate authentication to the portal server. During the authentication process, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.
- **Setting the SNMP Parameters Between the NAS and Portal Server**
 - (Mandatory) To enable Web authentication successfully, you must set the SNMP network management parameters used for the communication between the NAS and portal server.
 - The NAS or convergence device and portal server jointly manage authenticated clients through SNMP/MIB. A table of authenticated clients is managed by MIB on the NAS. The portal server is able to access the MIB to obtain client statistics so as to control client login and logout. When a client logs out, the NAS or convergence device will inform the portal server by Webauth Inform packets.
- **Enabling Nodexon First-Generation Web Authentication on an Interface**
 - Mandatory.
 - When Nodexon First-Generation Web Authentication is enabled in interface configuration mode, Web authentication is not enabled on any port by default. The users connecting to the port do not need to perform Web authentication.

Verification

- Check whether unauthenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

▾ Configuring the First-Generation Webauth Template

Command	web-auth template eportalv1
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	eportalv1 is the default template of Nodexon First-Generation Web Authentication.

▾ Configuring the IP Address of the Portal Server

Command	ip {ip-address}
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Webauth template configuration mode

Usage Guide	N/A
--------------------	-----

▾ Configuring the Webauth URL of the Portal Server

Command	url { <i>url-string</i> }
Parameter Description	<i>url-string</i> : Indicates the Webauth URL of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	The URL starts with http:// or https:// .

▾ Specifying the Webauth Binding Mode

Command	bindmode { ip-mac-mode ip-only-mode }
Parameter Description	Indicates the Webauth binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

▾ Configuring the Webauth Communication Key

Command	web-auth portal key { <i>key-string</i> }
Parameter Description	<i>key-string</i> : Indicates the Webauth communication key used for the communication between the NAS and portal server. The key contains up to 255 characters.
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring the SNMP-Server Community String

Command	snmp-server community { <i>community-string</i> } rw
Parameter Description	<i>community-string</i> : Indicates the community string. rw : Must be set to rw to support the read and write operations as the Set operation on MIB is required.
Command Mode	Global configuration mode
Usage Guide	The SNMP-server community string is used by the portal server to manage the online clients on the NAS or convergence device.

▾ Configuring the SNMP-Server Host

Command	snmp-server host { <i>ip-address</i> } inform version 2c { <i>community-string</i> } web-auth
Parameter Description	<i>ip-address</i> : Indicates the IP address of the SNMP-server host, that is, the portal server. <i>community-string</i> : Configures the community string used to send an SNMP Inform message.
Command	Global configuration mode

Mode	
Usage Guide	<p>Configure the SNMP-server host to receive Webauth messages, including the type, version, community string, and other parameters.</p> <p>inform: Enables the SNMP Inform function. The NAS or convergence device will send a message to the portal server when a client logs out. The message type is set to Inform instead of Trap to avoid message loss.</p> <p>version 2c: Indicates SNMPv2 for SNMP Inform is not supported in all SNMP versions excluding SNMPv1.</p> <p>web-auth: Indicates the preceding parameters to be used for Web authentication.</p> <hr/> <p>For details regarding SNMP configuration and others, see the <i>Configuring SNMP</i>.</p> <p>The SNMP parameter version 2c listed here is aimed at SNMPv2. SNMPv3 is recommended if higher security is required for the SNMP communication between the NAS and portal server. To use SNMPv3, change SNMP Community to SNMP User, version 2c to SNMPv3, and set SNMPv3-related security parameters. For details, see the <i>Configuring SNMP</i>.</p> <hr/>

📌 Enabling the Webauth Trap/Inform Function

Command	snmp-server enable traps web-auth
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure the NAS or convergence device to send Webauth Trap and Inform messages externally. web-auth: Indicates Web authentication messages.

📌 Enabling Nodexon First-Generation Web Authentication on an Interface

Command	web-auth enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

📌 Configuring Nodexon First-Generation Web Authentication

<p>Scenario Figure 5-4</p>	 <p>The diagram illustrates a network topology for web authentication. At the center is a Network Access Server (NAS) with IP address 192.168.197.95. The NAS is connected to four other components: the Internet (represented by a cloud icon), a Security Access Manager (SAM) server with IP address 192.168.197.80, a User with IP address 192.168.197.64, and an ePortal server with IP address 192.168.197.79.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● On the NAS, configure the IP address of the ePortal server and the key (Nodexon) used for communicating with the ePortal server. ● Configure the Webauth URL on the NAS. ● Set the SNMP network management parameters (community string: public) used for the communication between the NAS and ePortal server. ● Enable Web authentication on ports GigabitEthernet 0/2 and GigabitEthernet 0/3 on the NAS.
	<pre>Nodexon# config Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)#web-auth template eportalv1 Nodexon(config.tmpl.eportalv1)#ip 192.168.197.79 Nodexon(config.tmpl.eportalv1)#exit Nodexon(config)# web-auth portal key Nodexon</pre>
	<pre>Nodexon(config)# web-auth template eportalv1 Nodexon(config.tmpl.eportalv1)#url http://192.168.197.79:8080/eportal/index.jsp Nodexon(config.tmpl.eportalv1)#exit</pre>
	<pre>Nodexon(config)# snmp-server community public rw Nodexon(config)# snmp-server enable traps web-auth Nodexon(config)# snmp-server host 192.168.197.79 inform version 2c public web-auth Nodexon(config)# exit</pre>
	<pre>Nodexon(config)# interface range GigabitEthernet 0/2-3 Nodexon(config-if-range)# web-auth enable Nodexon(config-if-range)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Check whether Web authentication is configured successfully.

	<pre>Nodexon(config)#show running-config ... snmp-server host 192.168.197.79 inform version 2c public web-auth snmp-server enable traps web-auth snmp-server community public rw ... web-auth template eportalv1 ip 192.168.197.79 url http://192.168.197.79:8080/eportal/index.jsp ! web-auth portal key Nodexon ... interface GigabitEthernet 0/2 web-auth enable ! interface GigabitEthernet 0/3 web-auth enable</pre>
	<pre>Nodexon#show web-auth control Port Control Server Name Online User Count ----- ... GigabitEthernet 0/20n eportalv1 0 GigabitEthernet 0/30n eportalv1 0 ...</pre>
	<pre>Nodexon#show web-auth template Webauth Template Settings: ----- Name: eportalv1 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode</pre>

Type:	v1
.....	

Common Errors

- The SNMP parameters used for the communication between the portal server and NAS are configured incorrectly, causing authentication failures.
- Specify the IP-MAC binding mode to deploy Web authentication on layer-3 networks, causing authentication failures.
- When Web authentication is used in conjunction with VRRP, run the `snmp-server trap-source ip` command to specify the VRRP address; otherwise, the portal server cannot process Trap packets correctly.

5.4.2 Configuring Nodexon Second-Generation Web Authentication

Configuration Effect

Redirect unauthenticated clients to the Webauth URL to perform authentication. IPv6 is supported.

Notes

- Nodexon Second-Generation Web Authentication complies with the CMCC WLAN Service Portal Specification. Furthermore, it is extended to support Nodexon portal server. Perform compatible configuration based on the server performance in actual deployment. For details, see the subsequent chapter.
- The `cmcc-normal` and `cmcc-ext1` parameters in the `fmt` command support only IPv4. If IPv6 is used, the configuration of the portal server is invalid.

Configuration Steps

↳ Enabling AAA

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must enable AAA.
- The NAS is responsible for initiating authentication to the portal server through AAA in Nodexon Second-Generation Web Authentication.

↳ Configuring the RADIUS-Server Host and Communication Key

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must configure the RADIUS server.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

↳ Configuring an AAA Method List for Web Authentication

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must configure an AAA authentication method list.
- An AAA authentication method list associates Web authentication requests with the RADIUS server. The NAS selects an authentication method and server based on the method list.

↘ **Configuring an AAA Method List for Web Accounting**

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must configure an AAA method list for Web accounting.
- An accounting method list is used to associate an accounting method and server. In Web authentication, accounting is implemented to record client fees.

↘ **Configuring the Portal Server**

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must configure and apply the portal server.
- When the NAS or convergence device finds an unauthenticated client attempting to access network resources through HTTP, it redirects the access request to the specified Webauth URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, unauthenticated clients can directly visit this IP address through HTTP.

↘ **Configuring the Communication Key Between the NAS and Portal Server**

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must configure the key used for the communication between the NAS or convergence device and portal server.
- When the NAS finds an unauthenticated client attempting to access network resources, it redirects the client to the specified Webauth URL, where the client can initiate authentication to the portal server. During the authentication process, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

↘ **Configuring the Portal Server in Global or Interface Configuration Mode**

- (Mandatory) To enable Nodexon Second-Generation Web Authentication, you must specify the use of the second generation portal server in global or interface configuration mode.
- The NAS first selects the portal server in interface configuration mode. If such a portal server does not exist, the NAS selects the portal server in global configuration mode. If such a portal server does not exist, eportalv1 is used by default. The NAS redirects users to the selected portal server.

↘ **Enabling Nodexon Second-Generation Web Authentication on an Interface**

- Mandatory.
- When Nodexon Second-Generation Web Authentication is enabled in interface configuration mode, Web authentication is not enabled on any port by default. The users connecting to the port do not need to perform Web authentication.

Verification Check whether unauthenticated clients are required to perform authentication.

- Check whether authenticated clients can access the Internet normally.

Related Commands

↘ **Enabling AAA**

Command	aaa new-model
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	You can configure the AAA authentication and accounting method lists only after AAA is enabled.

↘ Configuring the RADIUS-Server Host and Communication Key

Command	radius-server host { <i>ip-address</i> } [auth-port <i>port-number1</i>] [acct-port <i>port-number2</i>] key { <i>string</i> }
Parameter	<i>ip-address</i> : Indicates the IP address of the RADIUS server host.
Description	<i>port-number1</i> : Indicates the authentication port. <i>port-number2</i> : Indicates the accounting port. <i>string</i> : Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812, and the accounting port number is 1813.

↘ Configuring an AAA Method List for Web Authentication

Command	aaa authentication web-auth { default <i>list-name</i> } <i>method1</i> [<i>method2...</i>]
Parameter	<i>list-name</i> : Creates a method list.
Description	<i>method1</i> : Configures method 1. <i>method2</i> : Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Nodexon Second-Generation Web Authentication adopts the RADIUS authentication method.

↘ Configuring an AAA Method List for Web Accounting

Command	aaa accounting network { default <i>list-name</i> } start-stop <i>method1</i> [<i>method2...</i>]
Parameter	<i>list-name</i> : Creates a method list.
Description	<i>method1</i> : Configures method 1. <i>method2</i> : Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Nodexon Second-Generation Web Authentication adopts the RADIUS accounting method.

↘ Configuring the Second-Generation Webauth Template

Command	web-auth template { <i>eportalv2</i> <i>portal-name v2</i> }
Parameter	<i>portal-name</i> : Indicates the customized portal server name.
Description	
Command Mode	Global configuration mode

Mode	
Usage Guide	eportalv2 indicates the default template of Nodexon Second-Generation Web Authentication.

▾ Configuring the IP Address of the Portal Server

Command	ip { <i>ip-address</i> }
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

▾ Configuring the Webauth URL of the Portal Server

Command	url { <i>url-string</i> }
Parameter Description	Indicates the Webauth URL of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	The URL starts with http:// or https:// .

▾ Configuring the Format of the Webauth URL

Command	fmt { cmcc-ext1 cmcc-ext2 cmcc-normal }
Parameter Description	Indicates the format of the Webauth URL.
Command Mode	Webauth template configuration mode
Usage Guide	The cmcc-normal and cmcc-ext1 parameters in the fmt command support only IPv4. The cmcc-ext2 is supported for Liaoning CMCC.

▾ Specifying the Template Binding Mode

Command	bindmode { ip-mac-mode ip-only-mode }
Parameter Description	Indicates the template binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

▾ Configuring the Webauth Communication Key

Command	web-auth portal key { <i>key-string</i> }
Parameter Description	<i>key-string</i> : Indicates the Webauth communication key used for the communication between the NAS and portal server. The key contains up to 255 characters.

Command Mode	Global configuration mode
Usage Guide	N/A

➤ **Enabling Nodexon Second-Generation Web Authentication on an Interface**

Command	web-auth enable {eportalv2 template-name}
Parameter Description	Indicates a Webauth template.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

➤ **Configuring Nodexon Second-Generation Web Authentication**

<p>Scenario Figure 5-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable AAA on the NAS. ● Configure the RADIUS-server host and communication key on the NAS. ● Configure the default AAA method lists for Web authentication and accounting on the NAS. ● Configure the IP address of the portal server and the Webauth communication key (Nodexon) used for communicating with the portal server on the NAS. ● Configure the Webauth URL on the NAS. ● Configure Nodexon Second-Generation Web Authentication in global configuration mode on the NAS.
	<pre>Nodexon#configure Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)#aaa new-model</pre>
	<pre>Nodexon(config)#radius-server host 192.168.197.79 key Nodexon</pre>
	<pre>Nodexon(config)#aaa authentication web-auth default group radius</pre>

	<pre>Nodexon(config)#aaa accounting network default start-stop group radius</pre>
	<pre>Nodexon(config)#web-auth template eportalv2 Nodexon(config.tmlt.eportalv2)#ip 192.168.197.79 Nodexon(config.tmlt.eportalv2)#exit Nodexon(config)#web-auth portal key</pre>
	<pre>Nodexon Nodexon(config)# web-auth template eportalv2 Nodexon(config.tmlt.eportalv2)#url http://192.168.197.79: 8080/eportal/index.jsp Nodexon(config.tmlt.eportalv2)#exit</pre>
	<pre>Nodexon(config)# interface range GigabitEthernet 0/2-3 Nodexon(config-if-range)# web-auth enable eportalv2</pre>
	<pre>Nodexon(config-if-range)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Check whether Web authentication is configured successfully.
	<pre>Nodexon(config)#show running-config ... aaa new-model aaa authentication web-auth default group radius aaa accounting network default start-stop group radius ... radius-server host 192.168.197.79 key Nodexon ... web-auth template eportalv2 ip 192.168.197.79 url http://192.168.197.79:8080/eportal/index.jsp ! web-auth portal key Nodexon ! web-auth enable ! interface GigabitEthernet 0/2 interface GigabitEthernet 0/3</pre>

<pre>Nodexon#show web-auth control Port Control Server Name Online User Count ----- ...Global On eportalv2 1 ... </pre>
<pre>Nodexon#show web-auth template Webauth Template Settings: ----- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode Type: v2 Port: 50100 State: Active Acctmlist: default Authmlist: default ... </pre>

Common Errors

- The communication key between the portal server and NAS is configured incorrectly or only on the portal server or NAS, causing authentication errors.
- The communication parameters of the RADIUS server and NAS are set incorrectly, causing authentication errors.
- The portal server does not support the *CMCC WLAN Service Portal Specification*, causing compatibility failure.

5.4.3 Specifying an Authentication Method List

Configuration Effect

- The portal server sends an authentication request to the NAS when a user submits authentication information. The NAS resolves the authentication server information and other information based on the configured authentication method list name before initiating authentication.
- The NAS selects the authentication server based on the specified authentication method list.

Notes

- Before you configure an authentication method list name, ensure that the authentication methods in the list have been configured on the AAA module. The command used to configure authentication methods on the AAA module is **aaa authentication web-auth { default | list-name }method1 [method2...]**.

Configuration Steps

- Optional.
- The default authentication method is used if no authentication method list is configured. Run the **authentication { mlist-name }** command to configure an authentication method list name when the authentication method list name on the AAA module needs to be modified or multiple method lists exist.

Verification

- Configure two authentication method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Create user a and configured a password for the user on server 1. Create user b on server 2.
- Configure the use of list 1.
- Perform authentication as user b and check that authentication fails.
- Perform authentication as user a and check that authentication is successful.

Related Commands

↘ Specifying an Authentication Method List

Command	authentication {mlist-name}
Parameter Description	Indicates a method list name.
Command Mode	Webauth template configuration mode
Usage Guide	Ensure that the configured authentication method list name is consistent with that on the AAA module.

5.4.4 Specifying an Accounting Method List

Configuration Effect

- The NAS sends an accounting request when a user passes authentication. The recipient of the request depends on the configuration of the accounting method list and is usually the portal server.
- Specify an accounting method list for the NAS to perform accounting.

Notes

- Ensure that the accounting method list has been configured on the AAA module. The command used to configure accounting methods on the AAA module is **aaa accounting network {default | list-name }start-stop method1 [method2...]**.

Configuration Steps

- Optional.
- The default accounting method is used if no accounting method list is configured. Run the **accounting** {*mlist-name*} command to configure an accounting method list name when the accounting method list name on the AAA module needs to be modified or multiple method list names exist.

Verification

- Configure two accounting method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Configure the use of list 1.
- Use a valid account to perform authentication to access the Internet.
- View user accounting information on server1 and server2. Check that the user accounting information exists only on server1.

Related Commands

▾ Specifying an Accounting Method List

Command	accounting { <i>mlist-name</i> }
Parameter Description	Indicates a method list name.
Command Mode	Webauth template configuration mode
Usage Guide	Ensure that the configured accounting method list name is consistent with that on the AAA module.

Configuration Example

▾ Specifying an Accounting Method List

Configuration Steps	<ul style="list-style-type: none"> ● Specify the accounting method list mlist1. <pre>Nodexon(config, tmplt, eportalv2)#accounting mlist1</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Nodexon#show web-auth template Webauth Template Settings: ----- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode</pre>

Configuration Steps	<ul style="list-style-type: none"> Specify the accounting method list m1ist1.
	<code>Nodexon(config, tmplt, eportalv2)#accounting m1ist1</code>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Type: v2 Port: 50100 State: Active Acctm1ist: m1ist1 Authm1ist: m1ist1</pre>

5.4.5 Configuring the Communication Port of the Portal Server

Configuration Effect

- When the NAS detects that a user logs out, it notifies the portal server. The NAS interacts with the portal server through the portal specification, which specifies the port number used to listen to and send/receive packets.
- When the listening port of the portal server is changed, the communication port of the portal server must be modified on the NAS to enable the NAS to interact with the portal server.
- In Nodexon iPortal Web Authentication, this function is used to configure the HTTP listening port of the NAS. The default port number is 8081.

Notes

- The configured port number must be consistent with the port actually used by the portal server.
- This function is applicable to Nodexon Second-Generation Web Authentication and iPortal Web Authentication. The two authentication schemes use different default port numbers. In Nodexon Second-Generation Web Authentication, the configured port number is used for the interaction between the NAS and portal server through the portal specification. In Nodexon iPortal Web Authentication, the configured port number is used for packet listening on the NAS.

Configuration Steps

- Optional.
- Run the **port** *port-num* command to maintain port configuration consistency when the portal server does not use the default port number or the listening port of the NAS conflicts with other port and needs to be adjusted.

Verification

- Configure Nodexon Second-Generation Web Authentication.
- Change the listening port of the server to 10000.
- Run the **port** *port-num* command to configure the port number 10000.

- Simulate the scenario where a user performs authentication to access the Internet.
- Force the user offline on the NAS, refresh the online page, and check that a user logout notification is displayed.

Related Commands

Configuring the Communication Port of the Portal Server

Command	<code>port port-num</code>
Parameter Description	<i>port-num</i> : Indicates the port number.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Communication Port of the Portal Server

Configuration Steps	<ul style="list-style-type: none"> ● Configure the communication port of the portal server as port 10000.
	<pre>Nodexon(config.tmlt.eportalv2)#port 10000</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Nodexon#show web-auth template Webauth Template Settings: ----- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-only-mode Type: v2 Port: 10000 Acctmlist: Authmlist:</pre>

5.4.6 Specifying the Webauth Binding Mode

Configuration Effect

- When a user goes online, the user's entry needs to be written to a forwarding rule. The forwarding rule mapping method can be modified by specifying different binding modes, which further affects the Internet access rules applied to users. In IP-only mode, all the packets carrying the specified IP address are permitted to pass, and the STAs who send the packets can access the Internet. In IP+MAC mode, only the packets carrying both the specified IP address and MAC address are permitted to pass, and the STAs who send the packets can access the Internet.

Notes

- In Layer-3 authentication, the MAC addresses visible to the NAS are the gateway addresses of STAs. Because these MAC addresses are not accurate, the IP-only mode should be used.

Configuration Steps

- (Optional) The default Webauth binding mode is IP+MAC.
- Determine a binding mode based on the accuracy of user information obtained by the NAS. When the IP and MAC addresses of STAs are accurate (in L2 authentication, for example), IP+MAC is recommended. When the IP and MAC addresses are not accurate, select IP-only.

Verification

- Change the binding mode to IP-only.
- Simulate the scenario where a user performs authentication to access the Internet.
- Modify the MAC address of the user, or use a client with the same IP address but a different MAC address to access the Internet.
- Check that the user accesses the Internet normally.

Related Commands

▾ Specifying the Webauth Binding Mode

Command	bindmode {ip-mac-mode ip-only-mode}
Parameter Description	ip-mac-mode: Indicates IP-MAC binding mode. ip-only-mode: Indicates IP-only binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Configuration Example

▾ Specifying the Webauth Binding Mode

Configuration Steps	<ul style="list-style-type: none"> ● Set the binding mode to IP-only.
	<pre>Nodexon(config,tmplt,eportalv2)#bindmode ip-only-mode</pre>

Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.

5.4.7 Configuring the Redirection HTTP Port

Configuration Effect

- When an STA accesses network resources (for example, the user accesses the Internet using a browser), the STA sends HTTP packets. The NAS or convergence device intercepts these HTTP packets to determine whether the STA is accessing network resources. If the NAS or convergence device detects that the STA is not authenticated, it prevents the STA from accessing network resources and displays an authentication page to the STA. By default, the NAS intercepts the HTTP packets that STAs send to port 80 to determine whether STAs are accessing network resources.
- After a redirection HTTP port is configured, the HTTP requests that STAs send to the specified destination port can be redirected.

Notes

- The commonly used management ports on the NAS or convergence device, such as ports 22, 23 and 53, and ports reserved by the system are not allowed to be configured as the redirection port. All ports except port 80 with numbers smaller than 1000 are seldom used by the HTTP protocol. To avoid a conflict with the well-known TCP port, do not configure a port with a small number as the redirection port unless necessary.

Configuration Steps

- Optional.
- When you configure automatic client acquisition, if you need to enable the NAS to intercept the HTTP packets that STAs send to the specified destination port, configure a redirection HTTP port.

Verification

- Configure an interception port.

- Open the browser of a PC and access the Internet through the port without performing authentication.
- Check whether the access requests are redirected to an authentication page.

Related Commands

Configuring the Redirection HTTP Port

Command	<code>http redirect port <i>port-num</i></code>
Parameter Description	<i>port-num</i> : Indicates the port number.
Command Mode	Global configuration mode
Usage Guide	A maximum of 10 different destination port numbers can be configured, not including default ports 80 and 443.

Configuration Example

Configuring the Redirection HTTP Port

Configuration Steps	<ul style="list-style-type: none"> ● Configure port 8080 as the redirection HTTP port.
	<pre>Nodexon(config)#http redirect port 8080</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Nodexon(config)#show web-auth rdport Rd-Port: 80 443 8080</pre>

5.4.8 Configuring Rate Limit Webauth Logging

Configuration Effect

- The Web authentication module sends syslog messages to the administrator to display the information and relevant events of users who perform login/logout. By default, syslog messages are shielded.
- After syslog output rate limiting is configured, syslog messages are sent at a certain rate.

Notes

- When the login/logout rate is high, syslog messages are output frequently, which affects device performance and results in spamming.

Configuration Steps

- Optional.

- Configure syslog output rate limiting when you need to view the syslog messages about user login/logout.

Verification

- Configure logging rate limiting.
- Check whether users log in and out at a certain rate.
- Check that syslog messages are printed out at the limit rate.

Related Commands

▾ Configuring Rate Limit Webauth Logging

Command	web-auth logging enable <i>num</i>
Parameter Description	<i>num</i> : Indicates the syslog output rate (entry/second).
Command Mode	Global configuration mode
Usage Guide	When the syslog output rate is set to 0 , syslog messages are output without limit. The output of syslog messages of the critical level and syslog messages indicating errors is not limited.

Configuration Example

▾ Configuring Rate Limit Webauth Logging

Configuration Steps	<ul style="list-style-type: none"> ● Disable rate limit Webauth Logging. <pre>Nodexon(config)#web-auth logging enable 0</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Nodexon(config)#show running-config ... web-auth logging enable 0 ...</pre>

5.4.9 Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Configuration Effect

- When an unauthenticated user accesses network resources, the user's PC sends requests for HTTP session connection. The NAS or convergence device intercepts the HTTP packets and redirects the user to a Web authentication page. To prevent an unauthenticated user from initiating too many HTTP connection requests and save

resources on the NAS, it is necessary to limit the maximum number of HTTP sessions that the unauthenticated user can initiate on the NAS.

- A user occupies an HTTP session when performing authentication, and the other application programs of the user may also occupy HTTP sessions. For this reason, it is recommended that the maximum number of HTTP sessions for an unauthenticated user be not set to 1. By default, each unauthenticated user can initiate 255 HTTP sessions globally, and each port supports up to 300 HTTP sessions initiated by unauthenticated clients.

Notes

- If the authentication page fails to be displayed during Web authentication, the maximum number of HTTP sessions may be reached. When this happens, the user can close the application programs that may occupy HTTP sessions and then perform Web authentication again.

Configuration Steps

- Optional.
- Perform this configuration when you need to change the maximum number of HTTP sessions that each unauthenticated user can initiate and the maximum number of HTTP sessions that unauthenticated clients can initiate on each port.
- Perform this configuration when you configure automatic SU client acquisition.

Verification

- Modify the maximum number of HTTP sessions that an unauthenticated user can initiate.
- Simulate the scenario where an unauthenticated user constructs identical sessions to connect to the NAS continuously.
- Simulate the scenario where the unauthenticated user accesses the Internet using a browser. Check whether the access requests are redirected and the NAS notifies the user that the maximum number of sessions is reached.

Related Commands

📌 Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Command	http redirect session-limit { <i>session-num</i> }[port { <i>port-session-num</i> }]
Parameter Description	<i>session-num</i> : Indicates the maximum number of HTTP sessions for unauthenticated clients. The value range is 1 to 255. The default value is 255. <i>port-session-num</i> : Indicates the maximum number of HTTP sessions on each port for authenticated clients. The value range is 1 to 65,535. The default value is 300.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

📌 Configuring the Maximum Number of HTTP Sessions for Unauthenticated Clients

Configuration Steps	<ul style="list-style-type: none"> Set the maximum number of HTTP sessions for unauthenticated clients to 3.
	<pre>Nodexon(config)#http redirect session-limit 3</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show web-auth parameter HTTP redirection setting: session-limit: 3 timeout: 3 Nodexon(config)#</pre>

5.4.10 Configuring the HTTP Redirection Timeout

Configuration Effect

- Configure the HTTP redirection timeout to maintain redirection connections. When an unauthenticated user tries to access network resources through HTTP, the TCP connection requests sent by the user will be intercepted and re-established with the NAS or convergence device. Then, the NAS or convergence device waits for the HTTP GET/HEAD packets from the user and responds with HTTP redirection packets to close the connection. The redirection timeout is intended to prevent the user from occupying the TCP connection for a long time without sending GET/HEAD packets. By default, the timeout for maintaining a redirection connection is 3s.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to change the timeout for maintaining redirection connections.

Verification

- Change the timeout period.
- Use a network packet delivery tool to set up a TCP connection.
- View the status of the TCP connection on the NAS. Check whether the TCP connection is closed when the timeout is reached.

Related Commands

↘ Configuring the HTTP Redirection Timeout

Command	<code>http redirect timeout { seconds }</code>
----------------	--

Parameter Description	<i>Seconds</i> : Indicates the timeout for maintaining redirection connections, in the unit of seconds. The value ranges from 1 to 10. The default value is 3s.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the HTTP Redirection Timeout

Configuration Steps	<ul style="list-style-type: none"> Set the HTTP redirection timeout to 5s.
	<pre>Nodexon(config)#http redirect timeout 5</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show web-auth parameter HTTP redirection setting: session-limit: 255 timeout: 5</pre>

5.4.11 Configuring the Straight-Through Network Resources

Configuration Effect

- After Web authentication or 802.1Xauthentication is enabled on a port, the users connecting to the port need to pass Web authentication or 802.1Xauthentication before accessing network resources.
- Perform this configuration to exempt users from authentication when accessing some network resources.
- If a website is configured as a network resource of authentication exemption, all users, including unauthenticated clients, can access the website. By default, authentication exemption is not configured, and unauthenticated clients are not allowed to access network resources.

Notes

- The maximum number of free resources and the maximum number of unauthenticated clients cannot exceed 1000 respectively. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be set.
- http redirect direct-site** is used to configure the straight-through URL address for users, and **http redirect** is used to configure the straight-through IP address of the Web authentication server. The addresses configured using the two commands can be accessed without authentication, but they have different usages. It is recommended not to configure the IP address of the Web authentication server by using **http redirect direct-site**.

Configuration Steps

- Optional.
- Run the **http redirect direct-site** command to enable unauthenticated clients to access network resources.

Verification

- Configure the straight-through network resources.
- Check whether unauthenticated clients can access the configured network resources using PCs.

Related Commands

⤵ Configuring the Straight-Through Network Resources

Command	http redirect direct-site { <i>ipv4-address</i> [<i>ip-mask</i>] [arp] <i>mac-address</i> range <i>startip-address</i> <i>endip-address</i> } [<i>description description-str</i>] [<i>group group-name</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the network exempt from authentication.</p> <p><i>ip-mask</i>: Indicates the mask of the IPv4 address of the network exempt from authentication.</p> <p><i>mac-address</i>: Indicates the destination MAC address of the network exempt from authentication.</p> <p><i>startip-address</i>: Indicates the start IP address of consecutive networks exempt from authentication.</p> <p><i>endip-address</i>: Indicates the end IP address of consecutive networks exempt from authentication.</p> <p><i>group-name</i>: Indicates the group to which the network exempt from authentication belongs.</p> <p><i>description-str</i>: Indicates the description of the network exempt from authentication.</p>
Command Mode	Global configuration mode
Usage Guide	To set authentication-exempted ARP resource, use the http redirect direct-arp command preferentially.

Configuration Example

⤵ Configuring the Straight-Through Network Resources

Configuration Steps	<ul style="list-style-type: none"> ● Configure the straight-through network resources as 192.168.0.0/16. <pre>Nodexon(config)#http redirect direct-site 192.168.0.0 255.255.0.0</pre>										
	<ul style="list-style-type: none"> ● Set the range of consecutive networks exempt from authentication to 10.0.0.1-12.0.0.1. <pre>Nodexon(config)# http redirect direct-site range 10.0.0.1 12.0.0.1</pre>										
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Nodexon(config)#show web-auth direct-site</pre> <p>Direct sites:</p> <table border="1"> <thead> <tr> <th>Address</th> <th>Mask</th> <th>ARP</th> <th>Binding Group</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>192.168.0.0</td> <td>255.255.0.0</td> <td>Off</td> <td>N/A</td> <td>N/A</td> </tr> </tbody> </table> <pre>Nodexon(config)#</pre>	Address	Mask	ARP	Binding Group	Description	192.168.0.0	255.255.0.0	Off	N/A	N/A
Address	Mask	ARP	Binding Group	Description							
192.168.0.0	255.255.0.0	Off	N/A	N/A							

- View the ARP cache on the PC (run the **arp -a** command in the Windows operating system) and check whether the PC learns the ARP address of the straight-through ARP resources.

Related Commands

↘ Configuring the Straight-Through ARP Resource Range

Command	http redirect direct-arp { <i>ip-address</i> [<i>ip-mask</i>] }
Parameter	<i>ip-address</i> : Indicates the IP address of free resources.
Description	<i>ip-mask</i> : Indicates the mask of free resources.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

↘ Configuring the Straight-Through ARP Resource

Configuration Steps	<ul style="list-style-type: none"> ● Configure the straight-through ARP resource as 192.168.0.0/16.
	<pre>Nodexon(config)#http redirect direct-arp 192.168.0.0 255.255.0.0</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.

5.4.13 Configuring an Authentication-Exempted Address Range

Configuration Effect

- Exempt users from Web authentication when accessing reachable network resources. By default, no authentication-exempted address range is configured. All users must pass Web authentication before accessing network resources.
- The authentication-exempted address range can be configured as an IP address range or MAC address range.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to allow unauthenticated clients to access network resources.

Verification

- Configure an authentication-exempted user.
- Check whether the user can access the Internet without authentication.

Related Commands

↘ Configuring an Authentication-Exempted Address Range

Command	web-auth direct-host { <i>ipv4-address</i> [<i>ipv4-mask</i>] [arp] [port <i>interface-name</i>] <i>mac-address</i> range <i>startip-address</i> <i>endip-address</i> } [<i>description</i> <i>description-str</i>] [<i>group</i> <i>group-name</i>]
Parameter Description	<p><i>ipv4-address</i>: Indicates the IPv4 address of the user exempt from authentication.</p> <p><i>ip-mask</i>: Indicates the mask of the IPv4 address of the user exempt from authentication.</p> <p><i>interface-name</i>: Indicates the name of the interface on which authentication exemption is enabled.</p> <p><i>mac-address</i>: Indicates the MAC address of the user exempt from authentication.</p> <p><i>startip-address</i>: Indicates the start IP address of consecutive users exempt from authentication.</p> <p><i>endip-address</i>: Indicates the end IP address of consecutive users exempt from authentication.</p> <p><i>group-name</i>: Indicates the group to which the user exempt from authentication belongs.</p> <p><i>description-str</i>: Indicates the description of the user exempt from authentication.</p>
Command Mode	Global configuration mode
Usage Guide	<p>The arp field is used to assign pass permissions to ARP packets. This field must be set when ARP check is enabled.</p> <p>After the port field is set, authentication exemption takes effect only on the configured interface.</p>

Configuration Example

↘ Configuring an Authentication-Exempted Address Range

Configuration Steps	<ul style="list-style-type: none"> ● Configure an authentication-exempted address range.
	<pre>Nodexon (config)# web-auth direct-host 192.168.197.64</pre>
	<ul style="list-style-type: none"> ● Set the range of consecutive users exempt from authentication to 10.0.0.1-12.0.0.1. <pre>Nodexon(config)# web-auth direct-host range 10.0.0.1 12.0.0.1</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.

5.4.14 Configuring the Interval for Updating Online User Information

Configuration Effect

- The NAS or convergence device maintains and periodically updates the information of online users, including users' online duration, to monitor the usage of network resources. When the online duration threshold is reached, users will be prevented from using network resources.

Notes

- The user information updating interval must be configured as 60 or multiple of 60; otherwise, the system will select the minimum multiple of 60 above and closest to the actual configuration as the interval.

Configuration Steps

- Optional.
- Perform this configuration to allow unauthenticated clients to access network resources.

Verification

- Configure the interval for updating online user information.
- View the information of online users after the update interval has elapsed.

Related Commands

Configuring the Interval for Updating Online User Information

Command	web-auth update-interval { seconds }
Parameter Description	<i>seconds</i> : Indicates the interval for updating online user information, in the unit of seconds. The value ranges from 30 to 3,600. The default value is 180s.
Command Mode	Global configuration mode
Usage Guide	To restore the default updating interval, run the no web-auth update-interval command in global

	configuration mode.
--	---------------------

Configuration Example

Configuring the Interval for Updating Online User Information

Configuration Steps	<ul style="list-style-type: none"> Set the interval for updating online user information to 60s.
	<pre>Nodexon (config)# web-auth update-interval 60</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show run include web-auth update-interval web-auth update-interval 60</pre>

5.4.15 Configuring Portal Detection

Configuration Effect

- Detect the availability of the active portal server periodically. When the active portal server is unavailable, the standby portal server takes over the services.
- Nodexon Second-Generation Web Authentication provides two detection methods. One is that the NAS constructs and sends portal packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Another is the NAS sends ping packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Because some servers or intermediate network segments filter ping packets, the first method is commonly used. The ping detection method is only used based on special requirements. In Nodexon First-Generation Web Authentication, the NAS connects to a port of the portal server and checks whether the port is reachable. If the portal is reachable, the NAS determines that the portal server is available.
- For the first method in the second-generation authentication, the interval of server availability detection is specified by the **interval** parameter, and the maximum number of packets that can be sent during each time of detection is specified by the **retransmit** parameter. If the portal server does not respond, the NAS determines that the portal server is unavailable. The timeout period for each packet is specified by the **timeout** parameter. The parameter settings are also supported by Nodexon First-Generation Web Authentication.
- Portal server detection takes effect for Nodexon First- and Second-Generation Web Authentication.
- If multiple portal servers are configured, these servers are working in active/standby mode.
- Multiple portal servers must be configured to realize failover when an error is detected on one server.
- Only one of the two detection methods can be used at a time in case of collision. If both detection methods are configured, a detection algorithm conflict will occur or the detection results will be inaccurate.

Notes

- The system will automatically select a detection method based on whether Nodexon First- or Second-Generation Web Authentication is used.

Configuration Steps

- Optional.
- Configure multiple portal server templates applicable to Nodexon First- or Second-Generation Web Authentication.

Verification

- Configure two portal server templates for Nodexon First- or Second-Generation Web Authentication. Make the first template point to an unavailable server and the second template point to an available server.
- When the Console displays a log indicating that the portal server is not available, simulate the scenario where a user opens a browser to perform login authentication. Check whether the user is redirected to the second portal server.

Related Commands

▾ Configuring Portal Detection

Command	web-auth portal-check [interval <i>intsec</i> [timeout <i>tosec</i>] [retransmit <i>retries</i>]
Parameter Description	<i>intsec</i> : Indicates the detection interval. The default value is 10s. <i>tosec</i> : Indicates the packet timeout period. The default value is 5s. <i>intsec</i> : Indicates the timeout retransmission times. The default value is 3 (times).
Command Mode	Global configuration mode
Usage Guide	In many network environments, only one portal server is deployed, and portal server detection does not need to be configured. If multiple portal servers exist, it is recommended that the parameters of portal server detection be not set to small values; otherwise, the NAS will send many packets within a short time, affecting performance.

Configuration Example

▾ Configuring Portal Detection

Configuration Steps	<ul style="list-style-type: none"> ● Configure portal detection. <pre>Nodexon(config)#web-auth portal-check interval 20 timeout 2 retransmit 2</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Nodexon(config)#show running-config</pre>

Configuration Steps	<ul style="list-style-type: none"> Configure portal detection.
	<pre>Nodexon(config)#web-auth portal-check interval 20 timeout 2 retransmit 2</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>... web-auth portal-check interval 20 timeout 2 retransmit 2 ...</pre>

5.4.16 Configuring Portal Escape

Configuration Effect

- Allow new users to access the Internet without authentication when the portal server is not available.

Notes

- To use the portal escape function, you must configure portal detection.
- If multiple portal servers are configured, the escape function takes effect only when all the portal servers are not available.
- The escape function is intended only for the portal server, instead of the RADIUS server.

Configuration Steps

- Optional.
- Configure portal detection.
- Configure portal escape.
- (Optional) Configure the nokick attribute.

Verification

- Configure a portal server and disable the server.
- Configure the portal detection and escape functions.
- When the NAS detects that the portal server is not available, check whether a client accesses the Internet without authentication.

Related Commands

↳ [Configuring Portal Escape](#)

Command	<code>web-auth portal-escape [nokick]</code>
----------------	--

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure portal escape if the continuity of some critical services on the network needs to be maintained when the portal server is faulty. You must configure portal detection when you use this function. If the nokick attribute is configured, the system does not force users offline when the escape function takes effect. If the nokick attribute is deleted, the system forces users offline.

Configuration Example

Configuring Portal Escape

Configuration Steps	<ul style="list-style-type: none"> Configure portal escape.
	<pre>Nodexon(config)#web-auth portal-escape</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show running-config ... web-auth portal-escape ...</pre>

5.4.17 Enabling DHCP Address Check

Configuration Effect

- Allow only the clients that are allocated with IP addresses through DHCP to perform authentication.

Notes

- To use the DHCP address check function, you must configure DHCP snooping.
- DHCP address check is supported only for IPv4.
- DHCP address check is applicable only to Nodexon Second-Generation Web Authentication and iPortal Web Authentication.
- The requirement that users obtain IP addresses through DHCP must be specified during network deployment. Those users cannot also use static IP addresses; otherwise, the existing users that use static IP addresses will be affected.
- If a few users need to use static IP addresses, configure these IP addresses as straight-through addresses, and these users are exempt from authentication.

- If DHCP address check needs to be enabled only on some interfaces or some VLANs of interfaces, disable the global DHCP address check and configure the VLAN range in which DHCP address check needs to be enabled in each interface.

Configuration Steps

- Optional.
- Enable DHCP snooping.
- Enable DHCP address check.

Verification

- Enable DHCP address check.
- Configure a static IP address that is not allocated by the DHCP server on a client.
- Connect the client to the Internet and check whether the STA cannot perform authentication.

Related Commands

↘ Enabling Global DHCP Address Check

Command	web-auth dhcp-check
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure DHCP address check to allow only the users who obtain IP addresses through DHCP to access the Internet. This function helps prevent the users who configure IP addresses without authorization from performing authentication to access the Internet.

↘ Enabling Interface-based DHCP Address Check

Command	web-auth dhcp-check {vlan [vlan-list]}
Parameter Description	vlan-list: Indicates the VLAN range in which DHCP address check needs to be enabled in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	If DHCP address check needs to be enabled only on some interfaces or some VLANs of interfaces, disable the global DHCP address check and configure the VLAN range in which DHCP address check needs to be enabled in each interface.

Configuration Example

↘ Enabling DHCP Address Check

Configuration Steps	<ul style="list-style-type: none"> ● Enable global DHCP address check.
	<pre>Nodexon(config)#web-auth dhcp-check</pre>
Configuration Steps	<ul style="list-style-type: none"> ● Enable interface-based DHCP address check.
	<pre>Nodexon(config-if-TenGigabitEthernet 3/1)# web-auth dhcp-check vlan 1,3-4</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful.
	<pre>Nodexon(config)#show running-config ... web-auth dhcp-check ... interface TenGigabitEthernet 3/1 web-auth dhcp-check vlan 1,3-4 ...</pre>

5.4.18 Configuring the Portal Communication Port

Configuration Effect

- Configure the port (source port) used for the communication between the NAS and portal server.

Notes

- Only one port can be configured for the communication between the NAS and portal server.

Configuration Steps

- Configure a port as the portal communication port.

Verification

- After Web authentication is enabled, capture a packet on the portal server during the authentication process and check whether the source IP address of the packet is the IP address of the specified port.

Related Commands

↳ Configuring the Portal Communication Port

Command	<code>ip portal source-interface <i>interface-type interface-num</i></code>
Parameter	N/A
Description	

Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring the Portal Communication Port

Configuration Steps	<ul style="list-style-type: none"> Configure an aggregate port as the portal communication port.
	<pre>Nodexon(config)#ip portal source-interface Aggregateport 1</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show running-config ip portal source-interface Aggregateport 1</pre>

5.4.19 Configuring VLAN-Based Authentication on a Port

Configuration Effect

- With this function enabled, clients in a VLAN configured on a port of the NAS can initiate authentication. Otherwise, the authentication will not start.

Notes

- This function supports configuration of multiple VLANs. If no VLAN is specified, Web authentication is implemented based on ports.

Configuration Steps

- Configure port-based Web authentication.
- Configure the VLAN for Web authentication.

Verification

- After Web authentication is enabled, specify the VLAN in which clients can initiate authentication. The HTTP packets sent outside the specified VLAN cannot be redirected.

Related Commands

▾ Configuring VLAN-Based Authentication on a Port

Command	web-auth vlan-control <i>vlan-list</i>
Parameter	<i>vlan-list</i> : Indicates the VLAN list to be authenticated.

Description	
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring VLAN-Based Authentication on a Port

Configuration Steps	<ul style="list-style-type: none"> Specify VLAN1 as the VLAN in which users can initiate authentication.
	<pre>Nodexon(config-if-GigabitEthernet 0/14)#web-auth vlan-control 1</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful.
	<pre>Nodexon(config)#show running-config ... web-auth vlan-control 1</pre>

5.4.20 Disabling ARP Detection

Configuration Effect

- Disable the detection of user migration after its IP address or MAC address migrates.

Notes

- Address migration attacks may occur after ARP detection is disabled. ARP detection can be disabled in global configuration mode or in interface configuration mode. The interface configuration has a higher priority than the global configuration, and ARP detection is enabled by default in both global configuration mode and interface configuration mode. When the **no web-auth station-move arp-detect** command is executed on an interface, ARP detection is not performed when users of the interface are migrated to other interfaces.

Configuration Steps

Disabling ARP Detection

- Disable ARP detection.

Command	no web-auth station-move arp-detect
Parameter Description	N/A
Command	Global configuration mode and interface configuration mode

Mode	
Usage Guide	ARP detection is enabled by default. The interface configuration has a higher priority than the global configuration. Disable ARP detection on an interface that does not need ARP detection to prevent transmission of ARP detection packets during migration.

Verification

- After ARP detection is disabled, configure MAC address migration notices on different authentication ports, and check whether the users that perform Web authentication can migrate.

Configuration Example

Disabling ARP Detection

Configuration Steps	<ul style="list-style-type: none"> ● Disable ARP detection. <pre>Nodexon(config)#no web-auth station-move arp-detect Nodexon(config-if-GigabitEthernet 2/1)#no web-auth station-move arp-detect</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the configuration is successful. <pre>Nodexon(config)#show running-config ... no web-auth station-move arp-detect interface GigabitEthernet 2/1 no web-auth station-move arp-detect</pre>

5.4.21 Upgrade Compatibility

Configuration Effect

- Some configuration commands are optimized in the 11.X series software and the command formats are changed. For details, see the subsequent description.
- The 10.X series software supports smooth upgrade without function loss. However, some commands are displayed in new formats after upgrade.
- When you run the commands in earlier formats in the **no** form in the 11.X series software, a message is displayed, indicating the **no** form is not supported. You need to perform the **no** operation in new command formats.

Configuration Steps

- It is recommended that you run commands in new formats.

Verification

- Check that function loss does not occur when the 10.X series software is upgraded to the 11.X series software, and commands are displayed and stored in new formats.
- The commands in new formats have the same functions as the commands in earlier formats.

Related Commands

↘ Configuring the IP Address of the Portal Server in Nodexon First-Generation Web Authentication

Command	<code>http redirect ip-address</code>
Parameter Description	<i>ip-address</i> : Indicates the ip address of the ePortal server in Nodexon First-Generation Web Authentication.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 template, and the ip command in template configuration mode is executed to configure and display the IP address of the portal server. For details, see section 5.4.1"Configuring Nodexon First-Generation Web Authentication."

↘ Configuring the URL of the Portal Server in Nodexon First-Generation Web Authentication

Command	<code>http redirect homepage url</code>
Parameter Description	<i>url</i> . Indicates the URL of the ePortal server in Nodexon First-Generation Web Authentication.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 template, and the ip command in template configuration mode is executed to configure and display the IP address of the portal server. For details, see section 5.4.1"Configuring Nodexon First-Generation Web Authentication."

↘ Configuring the Portal Server

Command	<code>portal-server [eportal1 eportalv2]</code>
Parameter Description	eportav1 : Indicates the information of the portal server used in Nodexon First-Generation Web Authentication. eportav2 : Indicates the information of the portal server used in Nodexon Second-Generation Web
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 or eportalv2 template, and relevant information is filled in. The main parameters of the portal server include the IP address and URL of the server. The original command will be replaced by the ip command and url command in the template.

↘ Configuring Web Authentication Control on a Port

Command	<code>web-auth port-control</code>
----------------	------------------------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	In the 11.X version, the command is converted into web-auth enable <type> , in which type specifies the type (first or second generation) of Web authentication. The default type is Nodexon First-Generation Web

Authentication.

↘ [Configuring the IP-Only Binding Mode](#)

Command	web-auth port-control ip-only-mode
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	In the 11.X version, the command is converted into an eportalv1 or eportalv2 template, depending on the actual configuration. The server binding mode is configured and displayed by using the bindmode command in template configuration mode. For details, see section 5.4.1 "Configuring Nodexon First-Generation Web Authentication" and section 5.4.2 "Configuring Nodexon Second-Generation Web

Authentication."

↘ [Configuring VLAN-Based Web Authentication](#)

Command	web-auth allow-vlan <i>list</i>
Parameter Description	<i>list</i> : Indicates the list of VLANs for which Web authentication is enabled.
Command Mode	Global configuration mode
Usage Guide	In the 11.X version, the command is converted into a command used to configure VLAN-based SCC authentication exemption.

↘ [Displaying the Configuration Information of Nodexon First-Generation Web Authentication](#)

Command	show http redirect
Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	In the 11.X version, the command is unavailable and changed to show web-auth template .

↘ [Displaying the Port Control Information](#)

Command	show web-auth port-control
Parameter Description	N/A

Command Mode	Privileged mode
Usage Guide	In the 11.X version, the command is unavailable and changed to show web-auth control .

Configuration Example

Configuring Nodexon First-Generation Web Authentication

Configuration Steps	<ul style="list-style-type: none"> Check that the NAS runs on the 10.X version and is configured with the IP address of the portal server used by Nodexon First-Generation Web Authentication.
	<pre>Nodexon(config)# http redirect 192.168.197.64</pre>
	<ul style="list-style-type: none"> Upgrade the NAS to 11.X.
Verification	<ul style="list-style-type: none"> Run the show running-config command after the upgrade and check whether the new command formats are used.
	<pre>Nodexon#sh running-config web-auth template eportalv1 Ip 192.168.197.64 !</pre>

5.4.22 Configuring the Authenticated User Logout Delay on a Port

Configuration Effect

- Configure the delay after which the authenticated clients connected to a port go offline when the port fails.

Configuration Steps

Configuring the Authenticated User Logout Delay on a Port

- Configure the authenticated user logout delay on a port in global configuration mode.

Command	web-auth linkdown-timeout
Parameter Description	timeout: Indicates the logout delay. The default value is 60s.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Check that the authenticated clients connected to the faulty port go offline after the configured time has elapsed.

Configuration Example

➤ **Configuring the Authenticated User Logout Delay on a Port**

Configuration Steps	<ul style="list-style-type: none"> Configure the logout delay. <pre>Nodexon (config)#web-auth linkdown-timeout {timeout}</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful. <pre>Nodexon (config)#show running-config</pre>

5.4.23 Enabling the Perception-Free Feature

Configuration Effect

- Enable the perception-free feature to maintain the online state of users after port migration.

Configuration Steps

➤ **Enabling the Perception-Free Feature in Global Configuration Mode**

Command	web-auth station-move auto
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Check that users do not go offline after migration.

Configuration Example

➤ **Configuring the Authenticated User Logout Delay on a Port**

Configuration Steps	<ul style="list-style-type: none"> Enable the perception-free feature. <pre>Nodexon (config)# web-auth station-move auto</pre>
Verification	<ul style="list-style-type: none"> Check whether the configuration is successful. <pre>Nodexon (config)#show running-config</pre>

5.5 Monitoring

Clearing

Description	Command
Forces users offline.	clear web-auth user { all ip <i>ip-address</i> mac <i>mac-address</i> name <i>name-string</i> }
Clears all the straight-through network resources.	clear web-auth direct-site
Clears all the authentication-exempted users.	clear web-auth direct-host

Displaying

Description	Command
Displays the basic parameters of Web authentication.	show web-auth parameter
Displays the Webauth template configuration.	show web-auth template
Displays the authentication-exempted host range.	show web-auth direct-host [range]
Displays the straight-through address range.	show web-auth direct-site [range]
Displays the straight-through ARP range.	show web-auth direct-arp
Displays the TCP interception port.	show web-auth rdport
Displays the online information of all users or specified users.	show web-auth user { all ip <i>ip-address</i> mac <i>mac-address</i> name <i>name-string</i> }
Displays the Webauth mapping information.	show web-auth ip-mapping
Displays the Webauth portal check information.	show web-auth portal-check
Displays online and offline records about users.	show web-auth syslog ip <i>ip-address</i>

Debugging

 System resources are occupied when debugging information is output. Disable the debugging switch immediately after use.

Description	Command
Debugs Web authentication.	debug web-auth all

6 Configuring SCC

6.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services, so that these access control and network security services can coexist on one device to meet diversified access and security control requirements in various scenarios.

Typical access control services are dot1x, Web authentication, Address Resolution Protocol (ARP) check, and IP Source Guard. The network security services include Access Control List (ACL), Network Foundation Protection Policy (NFPP), and anti-ARP gateway spoofing. When two or more access control or network security services are simultaneously enabled on the device, or when both access control and network security services are simultaneously enabled on the device, the SCC coordinates the coexistence of these services according to relevant policies.

 For details about the access control and network security services, see the related configuration guide. This document describes the SCC only.

Protocol and Standards

N/A

6.2 Application

Typical Application	Scenario
Access Control of Extended Layer 2 Campus Networks	Students on a campus network can access the Internet based on dot1x client authentication or Web authentication. ARP spoofing between the students should be prevented. In addition, terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

6.2.1 Access Control of Extended Layer 2 Campus Networks

Scenario

Students on a campus network of a university usually need to be authenticated through the dot1x client or Web before accessing the Internet, so as to facilitate accounting and guarantee the benefits of the university.

- The students can access the Internet through dot1x client authentication or Web authentication.
- ARP spoofing between the students is prevented, so as to guarantee the stability of the network.
- Terminal devices in some departments (such as the headmaster's office) can access the Internet without authentication.

Figure 6-1

<p>Remarks</p>	<p>A traditional campus network is hierarchically designed, which consists of an access layer, a convergence layer and a core layer, where the access layer performs user access control. On an extended Layer 2 campus network, however, user access control is performed by a core switch, below which access switches exist without involving any convergence device in between. The ports between the core switch and the access switches (such as switches B, C, and D in Figure 6-1) are all trunk ports.</p> <p>The user access switches B, C, and D connect to PCs in various departments via access ports, and VLANs correspond to sub VLANs configured on the downlink ports of the downlink ports of the core switch, so that access users are in different VLANs to prevent ARP spoofing.</p> <p>The core switch A connects to various servers, such as the authentication server and the DHCP server. Super VLANs and sub VLANs are configured on the downlink ports. One super VLAN correspond to multiple sub VLANs, and each sub VLAN represents an access user.</p>
-----------------------	--

Deployment

- On the core switch, different access users are identified by VLAN and port numbers. Each access user (or a group of access users) corresponds to one VLAN. The ports on each access switch that connect to downstream users are configured as access ports, and one user VLAN is assigned to each access user according to VLAN planning. The core switch does not forward ARP requests. The core switch replies to the ARP requests from authenticated users only, so as to prevent ARP spoofing. On the core switch A, user VLANs are regarded as sub VLANs, super VLANs are configured, and SVIs corresponding to the super VLANs are configured as user gateways.

- On the downlink ports of the core switch (switch A in this example) that connect to the teachers' living area and the students' living area, both dot1x authentication and Web authentication are enabled, so that users can freely select either authentication mode for Internet access.
- Any special department (such as the headmaster's office in this example) can be allocated to a particular VLAN, and this VLAN can be configured as an authentication-exemption VLAN so that users in this department can access the Internet without authentication.

6.3 Basic Concepts

Authentication-Exemption VLAN

Some special departments may be allocated to authentication-exemption VLANs to simplify network management, so that users in these departments can access network resources without authentication. For example, the headmaster's office can be divided into the authentication-exemption VLANs on the campus network, so that users in the headmaster's office can access the Internet without authentication.

IPv4 User Capacity

The number of IPv4 access users can be restricted to protect the access stability of online users on the Internet and improve the operational stability of the device.

 The number of IPv4 access users is not restricted by default; that is, a large number of users can get online after being authenticated, till reaching the maximum hardware capacity of the device.

 IPv4 access users include IP users (such as IP authenticated users) based on dot1x authentication, users based on Web authentication, and IP users manually bound (using IP source guard, ARP check, or other means).

Authenticated-User Migration

Online-user migration means that an online user can get authenticated again from different physical locations to access the network. On the campus network, however, for ease of management, students are usually requested to get authenticated from a specified location before accessing the Internet, but cannot get authenticated on other access ports. This means that the users cannot migrate. In another case, some users have the mobile office requirement and can get authenticated from different access locations. Then the users can migrate.

User Online-Status Detection

For a chargeable user, accounting starts immediately after the user passes the authentication and gets online. The accounting process does not end until the user actively gets offline. Some users, however, forget to get offline when leaving their PCs, or cannot get offline because of terminal problems. Then the users suffer certain economical losses as the accounting process continues. To more precisely determine whether a user is really online, we can preset a traffic value, so

that the user is considered as not accessing the Internet and therefore directly brought offline when the user's traffic is lower than the preset value in a period of time or there is not traffic of the user at all in a period of time.

Features

Feature	Function
Authentication-Exemption VLAN	Users in a specified VLAN can be configured as authentication-exemption users.
IPv4 User Capacity	The IPv4 user capacity of a specified interface can be restricted to guarantee the access stability of users on the Internet.
Authenticated-User Migration	You can specify whether the authenticated can migrate.
User Online-Status Detection	You can specify whether to detect the traffic of online users, so that a user is forced offline when the traffic of the user is lower than a preset value in a period of time.

6.3.1 Authentication-Exemption VLAN

Authentication-exemption VLANs are used to accommodate departments with special access requirements, so that users in these departments can access the Internet without authentication such as dot1x or Web authentication.

Working Principle

Suppose the authentication-exemption VLAN feature is enabled on a device. When the device detects that a packet comes from an authentication-exemption VLAN, access control is not performed. In this way, users in the authentication-exemption VLAN can access the Internet without authentication. The authentication-exemption VLAN feature can be regarded as a kind of applications of secure channels.

-  A maximum of 100 authentication-exemption VLANs can be configured.
-  The authentication-exemption VLANs occupy hardware entries. When access control such as authentication is disabled, configuring authentication-exemption VLANs has the same effect as the case where no authentication-exemption VLANs are configured. Therefore, it is recommended that authentication-exemption VLANs be configured for users who need to access the Internet without authentication, only when the access control function has been enabled.
-  Although packets from authentication-exemption VLANs are exempt from access control, they still need to be checked by a security ACL. If the packets of the users in an authentication-exemption VLAN are denied according to the security ACL, the users still cannot access the Internet.
-  In gateway authentication mode, the device does not initiate any ARP request to a user in an authentication-exemption VLAN, and the ARP proxy will not work. Therefore, in gateway authentication mode, users in different authentication-exemption VLANs cannot access each other unless the users have been authenticated.

6.3.2 IPv4 User Capacity

To improve the operational stability of the device and guard against brutal force impacts from unauthorized users, you can restrict the total number of IPv4 access users on a certain port of the device.

Working Principle

If the total number of IPv4 access users is restricted, new users going beyond the total number cannot access the Internet.

-  Only the switches support the restriction on the number of IPv4 access users.
-  The number of IPv4 access users is not restricted on the device by default, but depends on the hardware capacity of the device.
-  The number of IPv4 access users includes the IPv4 authenticated users based on dot1x authentication, IPv4 users based on Web authentication, and IPv4 users based on various binding functions. Because the number of IPv4 access users is configured in interface configuration mode, the restriction includes both the number of IPv4 users generated on the port and IPv4 users globally generated. For example, you can set the maximum number of IPv4 access users on the Gi 0/1 port to 2, run commands to bind an IPv4 user to the port, and then run commands to bind a global IPv4 user to the port. Actually there are already two access users on the port. If you attempt to bind another IPv4 user or another global IPv4 user to the port, the binding operation fails.

6.3.3 Authenticated-User Migration

On an actual network, users do not necessarily access the Internet from a fixed place. Instead, users may be transferred to another department or office after getting authenticated at one place. They do not actively get offline but remove network cables and carry their mobile terminals to the new office to access the network. Then this brings about an issue about authenticated-user migration. If authenticated-user migration is not configured, a user who gets online at one place cannot get online at another place without getting offline first.

Working Principle

When authenticated-user migration is enabled, the dot1x or Web authentication module of the device detects that the port number or VLAN corresponding to a user's MAC address has changed. Then the user is forced offline and needs to be authenticated again before getting online.

-  Only the switches support authenticated-user migration. In addition, cross-switch migration is not supported. For example, authentication and migration are enabled on two N18000, and a user gets online after being authenticated on one of the two N18000. If the user attempts to migrate to the other N18000, the migration fails.
-  The authenticated-user migration function requires a check of users' MAC addresses, and is invalid for users who have IP addresses only.
-  The authenticated-user migration function enables a user who gets online at one place to get online at another place without getting offline first. If the user gets online at one place and then gets offline at that place, or if the user does not get online before moving to another place, the situation is beyond the control range of authenticated-user migration.
-  During migration, the system checks whether the VLAN ID or port number that corresponds to a user's MAC address has changed, so as to determine whether the user has migrated. If the VLAN ID or port number is the same, it indicates that the user does not migrate; otherwise, it indicates that the user has migrated. According to the preceding principle, if another user on the network uses the MAC address of an online user, the system will wrongly disconnect the online user unless extra judgment is made. To prevent such a problem, the dot1x or Web authentication will check whether a user has actually migrated. For a user who gets online through Web authentication or dot1x authentication with IP

authorization, the dot1x or Web authentication sends an ARP request to the original place of the user if detecting that the same MAC address is online in another VLAN or on another port. If no response is received within the specified time, it indicates that the user's location has indeed changed and then the migration is allowed. If a response is received within the specified time, it indicates that the user actually does not migrate and a fraudulent user may exist on the network. In the latter case, the migration is not performed. The ARP request is sent once every second by default, and sent for a total of five times. This means that the migration cannot be confirmed until five seconds later. Timeout-related parameters, including the probe interval and probe times, can be changed using the **arp retry times times** and **arp retry interval interval** commands. For details about the specific configuration, see *ARP-SCG.doc*. It should be noted that the migration check requires the configuration of IP authorization for users based on dot1x authentication. In addition, the ARP probe is triggered only for user migration in gateway authentication mode but not triggered for user migration in access authentication mode.

6.3.4 User Online-Status Detection

After a user accesses the Internet, the user may forget to get offline or cannot actively get offline due to terminal faults. In this case, the user will keep being charged and therefore will suffer a certain economical loss. To protect the benefits of users on the Internet, the device provides a function to detect whether the users are really online. If the device considers that a user is not online, the device actively disconnects the user.

Working Principle

A specific detection interval is preset on the device. If a user's traffic is lower than a certain value in this interval, the device considers that the user is not using the network and therefore directly disconnects the user.

-  The switches support the user online-status detection function.
-  The user online-status detection function applies to only users who get online through dot1x or Web authentication.
-  Currently, the N18000 supports zero-traffic detection only.
-  Currently, due to hardware chip restrictions of the N18000, the time to disconnect a user without any traffic relates to the configured MAC address aging time. If the traffic detection interval is set to m minutes and the MAC address aging time is set to n minutes, the interval from the moment when an authenticated user leaves the network without actively getting offline to the moment when the user is disconnected upon detection of zero traffic is about $[m, m+n]$ minutes. In other words, if an online user does not incur any Internet access traffic, the user is disconnected about $[m, m+n]$ minutes later.

6.4 Configuration

Configuration Item	Suggestions and Related Commands	
Configuring Authentication-Exemption VLANs	 Optional configuration, which is used to specify the users of which VLANs can access the Internet without authentication.	
	[no] direct-vlan	Configures authentication-exemption VLANs.
Configuring the IPv4 User Capacity	 Optional configuration, which is used to specify the maximum number of users who are allowed to access a certain interface.	
	[no] nac-author-user maximum	Configures the number of IPv4 users who are allowed to access a certain interface.
Configuring Authenticated-User Migration	 Optional configuration, which is used to specify whether online users with static MAC addresses can migrate.	
	[no] station-move permit	Configures whether authenticated users can migrate.
Configuring User Online-Status Detection	 Optional configuration, which is used to specify whether to enable the user online-status detection function.	
	offline-detect interval threshold	Configures the parameters of the user online-status detection function.
	no offline-detect	Disables the user online-status detection function.
	default offline-detect	Restores the default user online-status detection mode.

6.4.1 Configuring Authentication-Exemption VLANs

Configuration Effect

Configure authentication-exemption VLANs, so that users in these VLANs can access the Internet without experiencing dot1x or Web authentication.

Configure authentication-exemption VLANs on a port, so that only users in specified VLANs on the port can access the Internet without experiencing authentication.

Precautions

Authentication-exemption VLANs only mean that users in these VLANs do not need to experience a check related to access authentication, but still need to experience a check based on a security ACL. If specified users or VLANs are denied according to the security ACL, corresponding users still cannot access the Internet. Therefore, during ACL configuration, you

need to ensure that specified VLANs or specified users in the authentication-exemption VLANs are not blocked if you hope that users in the authentication-exemption VLANs can access the Internet without being authenticated.

Configuration Method

↘ Configuring Authentication-Exemption VLANs

- Optional configuration. To spare all users in certain VLANs from dot1x or Web authentication, configure these VLANs as authentication-exemption VLANs.
- Perform this configuration on access, convergence, or core switches depending on user distribution.
- Authentication-exemption VLANs can be configured in interface configuration mode.

Command	[no] direct-vlan <i>vlanlist</i>
Parameter Description	no: If the command carries this parameter, it indicates that the authentication-exemption VLAN configuration will be deleted. <i>vlanlist:</i> This parameter indicates the list of authentication-exemption VLANs to be configured or deleted.
Defaults	No authentication-exemption VLAN has been configured.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure or delete authentication-exemption VLANs.

Verification

Check the authentication-exemption VLAN configuration using the following method:

- Enable dot1x authentication on downlink ports that connect to user terminals, add the downlink ports that connect to the user terminals to a specific VLAN, and configure the VLAN as an authentication-exemption VLAN. Then open the Internet Explorer, and enter a valid extranet address (such as www.google.com). If the users can open the corresponding webpage on the Internet, it indicates that the authentication-exemption VLAN is valid; otherwise, the authentication-exemption VLAN does not take effect.
- Use the **show direct-vlan** command to check the authentication-exemption VLAN configuration on the device.

Command	show direct-vlan
Parameter Description	-
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Global configuration mode
Usage Example	Nodexon#show direct-vlan direct-vlan 100

Configuration Examples

 The following configuration example describes SCC-related configuration only.

Configuring Authentication-exemption VLANs so that Specific Users Can Access the Internet Without Being Authenticated

<p>Scenario Figure 6-2</p>	<p>The diagram illustrates a network architecture. At the top, a Router is connected to the Internet. The Router's G0/1 interface has IP 192.168.5.2, and its G2/20, SVI 7 interface has IP 192.168.5.1. Below the Router is Switch A, which acts as the core gateway. Switch A's G2/1 interface has SVI 100 with IP 192.168.100.1. Switch A is connected to three other switches: Switch B (Office Area), Switch C (Staff Living Area), and Switch D (Student Living Area). These connections are labeled as 'Trunk'. Switch A's G2/3 and G2/2 interfaces are connected to Switch B and Switch C, respectively. Switch A's SVI 200 has IP 192.168.200.1. The Core Layer includes SVI 1000 with IP 192.168.300.1, with a Supper vlan 1000 and Sub vlan: 1001-2000. The Office Area (Switch B) contains a Headmaster's Office (VLAN 100) with a Network Segment of 192.168.100.0/24 and a Gateway of 192.168.100.1/24. The Staff Living Area (Switch C) contains a VLAN 201-900 with a Network Segment of 192.168.200.0/24 and a Gateway of 192.168.200.1/24. The Student Living Area (Switch D) contains a VLAN 1001-2000 with a Network Segment of 192.168.300.0/24 and a Gateway of 192.168.300.1/24. Each area contains PC1 and PC2.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> On switch A (which is the core gateway device), set the GI 2/1 port as a trunk port, and enable dot1x authentication on this port. On switch A (which is the core gateway device), configure VLAN 100 to which the headmaster's office belongs as an authentication-exemption VLAN.
<p>Switch A</p>	<pre>SwitchA(config)#vlan 100 SwitchA(config-vlan)#exit SwitchA(config)#direct-vlan 100 SwitchA(config)#int GigabitEthernet 0/1 SwitchA(config-if-GigabitEthernet 0/1)#switchport mode trunk SwitchA(config-if-GigabitEthernet 0/1)#dot1x port-control auto *Oct 17 16:06:45: %DOT1X-6-ENABLE_DOT1X: Able to receive EAPOL packet and DOT1X authentication enabled.</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Open the Internet Explorer from any PC in the headmaster's office, enter a valid extranet address, and confirm that the corresponding webpage can be opened. Use the show direct-vlan command to check whether the authentication-exemption VLAN is valid.

Switch A	<pre>SwitchA(config)#show direct-vlan direct-vlan 100</pre>
-----------------	---

6.4.2 Configuring the IPv4 User Capacity

Configuration Effect

Configure the IPv4 user capacity, so as to restrict the number of users who are allowed to access an access port.

Precautions

N/A

Configuration Method

📌 Configuring the IPv4 User Capacity

- Optional configuration. To limit the maximum of users who are allowed to access an access port, configure the IPv4 user capacity. The access user capacity is not limited on an access port by default. Suppose the user capacity limit is configured on a specific interface. When the number of authenticated users on the interface reaches the maximum, new users cannot be authenticated on this interface and cannot get online, until existing authenticated users get offline on the interface.
- Perform this configuration on access switches, which may be access switches on the network edge or core gateway devices.

Command	nac-author-user maximum <i>max-user-num</i> no nac-author-user maximum
Parameter Description	no : If the command carries this parameter, it indicates that the limit on the IPv4 access user capacity will be removed from the port. <i>max-user-num</i> : This parameter indicates the maximum number of IPv4 users who allowed to access the port. The value range is from 1 to 1024.
Defaults	The number of IPv4 access users is not limited.
Command Mode	Interface configuration mode
Usage Guide	Use this command to limit the number of IPv4 access users on a specific access port.

Verification

Check the IPv4 user capacity configuration on a port using the following method:

- dot1x authentication: When the number of users who get online based on 1x client authentication on the port reaches the specified user capacity, no any new user can get online from this port.
- Web authentication: When the number of users who get online based on Web authentication on the port reaches the specified user capacity, no any new user can get online from this port.

- Use the **show nac-author-user [interface interface-name]** command to check the IPv4 user capacity configured on the device.

Command	show nac-author-user [interface interface-name]
Parameter Description	interface-name: This parameter indicates the interface name.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Global configuration mode
Usage Example	<pre>Nodexon#show nac-author-user interface GigabitEthernet 0/1 Port Cur_num Max_num ----- - Gi0/1 0 4</pre>

Configuration Examples

i The following configuration example describes SCC-related configuration only.

Restricting the Number of IP4 Users on a Port to Prevent Excessive Access Terminals from Impacting the Network

Scenario Figure 6-3	<p>The diagram shows a central switch labeled 'Switch A'. It is connected to an 'Internet' cloud via 'GigabitEthernet 0/1'. It has two other interfaces: 'GigabitEthernet 0/2' and 'GigabitEthernet 0/3'. Each of these two interfaces is connected to a separate oval representing a 'Student Dept'. Inside each 'Student Dept' oval, there are two PC icons labeled 'PC1' and 'PC2', with an ellipsis indicating more PCs.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Assume that the dot1x authentication environment has been well configured on the access switch A, and dot1x authentication is enabled on the Gi 0/2 port. ● Set the maximum number of IPv4 access users on the Gi 0/2 port to 4.
Switch A	<pre>SwitchA(config)#int GigabitEthernet 0/2 SwitchA(config-if-GigabitEthernet 0/2)#nac-author-user maximum 4</pre>
Verification	<ul style="list-style-type: none"> ● Perform dot1x authentication for all the four PCs in the dormitory, so that the PCs get online. Then take an additional terminal to access the network, and attempt to perform dot1x authentication for this terminal. Verify that the terminal cannot be successfully authenticated to get online.

	<ul style="list-style-type: none"> Use the show nac-author-user command to check whether the configuration has taken effect.
Switch A	<pre>SwitchA(config)#show nac-author-user Port Cur_num Max_num ----- - Gi0/1 0 4</pre>

6.4.3 Configuring Authenticated-User Migration

Configuration Effect

By default, when a user gets online after passing dot1x or Web authentication at a physical location (which is represented by a specific access port plus the VLAN number) and quickly moves to another physical location without getting offline, the user cannot get online through dot1x or Web authentication from the new physical location, unless the authenticated-user migration feature has been configured in advance.

Precautions

- If the authenticated-user migration feature is not yet configured, an online user cannot get online from the new physical location after quickly moving from one physical location to another physical location without getting offline first. However, if the user gets offline before changing the physical location or gets offline during the location change (for example, the user online-status detection function disconnects the user), the user can still normally get online after being authenticated at the new physical location, even if the authenticated-user migration feature is not configured.
- After moving to the new physical location, the online user needs to perform dot1x or Web authentication so as to get online.

Configuration Method

▾ Configuring Authenticated-User Migration

- Optional configuration. To allow users to be authenticated and get online from different physical locations, enable the authenticated-user migration function.
- Perform this configuration on access, convergence, or core switches depending on user distribution.

Command	[no] station-move permit
Parameter Description	no station-move permit: Indicates that authenticated-user migration is not permitted. station-move permit: Indicates that authenticated-user migration is permitted.
Defaults	Authenticated-user migration is not permitted; that is, when a user getting online from one physical location on the network moves to another physical location and attempts to get online from the new physical location without getting offline first, the authentication fails and the user cannot get online from the new physical location.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure authenticated-user migration.

Verification

Check the authenticated-user migration configuration using the following method:

- A PC is authenticated and gets online from a dot1x-based port of the device using dot1x SU client, and does not actively get offline. Move the PC to another port of the device on which dot1x authentication is enabled, and perform dot1x authentication again. Check whether the PC can successfully get online.

Configuration Examples

i The following configuration example describes SCC-related configuration only.

Configuring Online-User Migration so that an Online User Can Perform Authentication and Get Online from Different Ports Without Getting Offline First

<p>Scenario Figure 6-4</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable dot1x authentication on access ports Gi 0/2 and Gi 0/3, and configure authentication parameters. The authentication is MAC-based. ● Configure online-user migration.
<p>Switch A</p>	<pre>swl(config)#station-move permit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● A lap-top PC in the R&D department performs authentication using dot1x SU client, and gets online. Remove the network cable from the PC, connect the PC to the LAN where the test department resides, and perform dot1x authentication for the PC again using dot1x SU client. Confirm that the PC can successfully get online.
<p>Switch A</p>	<pre>swl(config)#show running-config include station</pre>

	station-move permit
--	---------------------

6.4.4 Configuring User Online-Status Detection

Configuration Effect

After the user online-status detection function is enabled, if a user's traffic is lower than a certain threshold within the specified period of time, the device automatically disconnects the user, so as to avoid the economical loss incurred by constant charging to the user.

Precautions

It should be noted that if disconnecting zero-traffic users is configured, generally software such as 360 Security Guard will run on a user terminal by default. Then such software will send packets time and again, and the device will disconnect the user only when the user's terminal is powered off.

Configuration Method

▾ Configuring User Online-Status Detection

- Optional configuration. A user is disconnected if the user does not involve any traffic within eight hours by default.
- Perform this configuration on access, convergence, or core switches depending on user distribution. The configuration acts on only the configured device instead of other devices on the network.
- If the traffic threshold parameter `threshold` is set to 0, it indicates that zero-traffic detection will be performed.

Command	offline-detect interval <i>interval</i> threshold <i>threshold</i> no offline-detect default offline-detect
Parameter Description	<i>interval</i> : This parameter indicates the offline-detection interval. The value range is from 6 to 65535 in minutes on a switch or from 1 to 65535 in minutes on a non-switch device. The default value is 8 hours, that is, 480 minutes. <i>threshold</i> : This parameter indicates the traffic threshold. The range depends on the chip. The default value is 0, indicating that the user is disconnected when no traffic of the user is detected. no offline-detect : Disables the user online-status detection function. default offline-detect : Restores the default value. In other words, an online user will be disconnected when the device detects that the user does not have any traffic within eight hours.
Defaults	8 hours
Command Mode	Global configuration mode
Usage Guide	Use this command to configure user online-status detection, so that a user is disconnected when its traffic is lower than a specific threshold within a specific period of time. Use the no offline-detect command to disable the user online-status detection function, or use the default offline-detect command to restore the default detection mode.

Verification

Check the user online-status detection configuration using the following method:

- After the user online-status detection function is enabled, power off the specified authenticated terminal after the corresponding user gets online. Then wait for the specified period of time, and run the online user query command associated with dot1x or Web authentication on the device to confirm that the user is already offline.

Configuration Examples

i The following configuration example describes SCC-related configuration only.

Configuring User Online-Status Detection so that a User Is Disconnected if the User Does Not Have Traffic Within Five Minutes

<p>Scenario Figure 6-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable dot1x authentication on the access port Gi 0/2, and configure authentication parameters. The authentication is MAC-based. ● Configure user online-status detection so that a user is disconnected if the user does not have traffic within five minutes.
<p>Switch A</p>	<pre>sw1(config)# offline-detect interval 5 threshold 0</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Perform dot1x authentication using dot1x SU client for a PC in the R&D department, so that the PC gets online. Then power off the PC, wait for 6 minutes, and run the online user query command available with dot1x authentication on switch 1 to confirm that the user of the PC is already offline.
<p>Switch A</p>	<pre>sw1(config)#show running-config include offline-detect</pre>

```
offline-detect interval 5
```

6.5 Monitoring

Displaying

Command	Function
show direct-vlan	Displays the authentication-exemption VLAN configuration.
show nac-author-user [interface <i>interface-name</i>]	Displays information about IPv4 user entries on a specific interface.

Debugging

 System resources are occupied when debugging information is output. Therefore, close the debugging switch immediately after use.

Command	Function
debug scc event	Debugs the SCC running process.
debug scc user [mac author mac]	Debugs SCC user entries.
debug scc acl-show summary	Debugs ACLs stored in the current SCC and delivered by various services.
debug scc acl-show all	Debugs all ALCs stored in the current SCC.

7 Configuring Global IP-MAC Binding

7.1 Overview

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

The address bounding feature is used to verify the input packets. Note that the address binding feature takes precedence over the 802.1X authentication, port security, and access control list (ACL).

7.2 Applications

Application	Description
Global IP-MAC Binding	Only hosts with the specified IP addresses can access the network, and the hosts connected to a device can move freely.

7.2.1 Global IP-MAC Binding

Scenario

The administrator assigns a fixed IP address for each host to facilitate management.

- Only hosts with the specified IP addresses can access the external network, which prevents IP address embezzlement by unauthorized hosts.
- Hosts can move freely under the same device.

Figure 7-1

Remarks	A is an access device. A user is a host configured with a static IP address.
----------------	---

IP Network is an external IP network.

Deployment

- Manually configure the global IP-MAC binding. (Take three users as an example.)

User	MAC Address	IP Address
User 1	00d0.3232.0001	192.168.1.10
User 2	00d0.3232.0002	192.168.1.20
User 3	00d0.3232.0003	192.168.1.30

- Enable the IP-MAC binding function globally.
- Configure the uplink port (Gi0/5 port in this example) of the device as the exclude port.

7.3 Features

Basic Concepts

IPv6 Address Binding Mode

IPv6 address binding modes include Compatible, Loose, and Strict. The default mode is Strict. If IPv4-MAC binding is not configured, the IPv6 address binding mode does not take effect, and all IPv4 and IPv6 packets are allowed to pass through. If IPv4-MAC binding is configured, the IPv6 address binding mode takes effect, and the device forwards IPv4 and IPv6 packets based on the forwarding rules described in the following table:

Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the global IPv4-MAC binding are forwarded.	Packets matching the global IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)
Loose	Packets matching the global IPv4-MAC binding are forwarded.	If IPv6+MAC address binding is configured, packets matching the IPv6-MAC binding are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.) If IPv6-MAC binding does not exist, all IPv6 packets are forwarded.
Compatible	Packets matching the global IPv4-MAC binding are forwarded.	If the IPv6 packets contain a MAC address matching the MAC address in the IPv4-MAC binding, the IPv6 packets are forwarded. Packets matching the global IPv6-MAC binding conditions are forwarded. (The binding is generated by other access security functions, such as port security and IPv6 Source Guard.)

Exclude Port

By default, the IP-MAC binding function takes effect on all ports of the device. You can configure exclude ports so that the address binding function does not take effect on these ports. In practice, the IP-MAC bindings of the input packets on the uplink port are not fixed. Generally, the uplink port of the device is configured as the exclude port so that the packets on the uplink port are not checked for IP-MAC binding.

Overview

Feature	Description
Configuring Global IP-MAC Binding	Control forwarding of IPv4 or IPv6 packets.
Configuring the IPv6 Address Binding Mode	Change the IPv6 packet forwarding rules.
Configuring the Exclude Port	Disable the global address binding function on the specified port.

7.3.1 Configuring Global IP-MAC Binding

Working Principle

Enable the global IP-MAC binding function manually to verify the input packets. If a specified IP address is bound with a MAC address, the device receives only the IP packets containing matched IP address and MAC address. The other packets are discarded.

Related Configuration

▾ [Configuring IP-MAC Binding](#)

Run the **address-bind** command in global configuration mode to add or delete an IPv4-MAC binding.

▾ [Enabling the IP-MAC Binding Function](#)

Run the **address-bind install** command in global configuration mode to enable the IP-MAC binding function. By default, this function is disabled.

7.3.2 Configuring the IPv6 Address Binding Mode

Working Principle

After the global IPv4-MAC binding is configured and enabled, IPv6 packets are forwarded based on the IPv6 address binding mode. IPv6 binding modes include Compatible, Loose, and Strict.

Related Configuration

▾ [Configuring the IPv6 Address Binding Mode](#)

By default, the IPv6 address binding mode is Strict.

Run the **address-bind ipv6-mode** command to specify an IPv6 address binding mode.

7.3.3 Configuring the Exclude Port

Working Principle

Configure an exclude port so that the address binding function does not take effect on this port.

Related Configuration

↘ [Configuring the Exclude Port](#)

Run the **address-bind uplink** command to configure an exclude port. By default, no port is the exclude port.

7.4 Configuration

Configuration	Description and Command	
Configuring Global IP-MAC Binding	 (Mandatory) It is used to configure and enable address binding.	
	address-bind	Configures a global IPv4-MAC binding.
	address-bind install	Enables the address binding function.
	address-bind binding-filter logging	Configures a logging filter of global IPv4-MAC binding.
Configuring the IPv6 Address Binding Mode	 (Optional) It is used to configure the IPv6 address binding mode.	
	address-bind ipv6-mode	Configures the IPv6 address binding mode.
Configuring the Exclude Port	 (Optional) It is used to disable the address binding function on a specified port.	
	address-bind uplink	Configures an exclude port.

7.4.1 Configuring Global IP-MAC Binding

Configuration Effect

- Configure a global IPv4-MAC binding.
- Enable the address binding function to control forwarding of the IPv4 or IPv6 packets.

Notes

- If you run the **address-bind install** command without IP-MAC binding configured, IP-MAC binding does not take effect and all packets are allowed to pass through.

Configuration Steps

↘ [Configuring Global IP-MAC Binding](#)

- (Mandatory) Perform this configuration in global configuration mode.

↘ [Enabling the Address Binding Function](#)

- (Mandatory) Perform this configuration in global configuration mode.

↘ [Configuring a Logging Filter of Global IP-MAC Binding](#)

- (Optional) Perform this configuration in global configuration mode.

Verification

Run the **show run** or **show address-bind** command to check whether the configuration takes effect.

Related Commands

↘ [Configuring Global IP-MAC Binding](#)

Command	address-bind { <i>ip-address</i> <i>ipv6-address</i> } <i>mac-address</i>
Parameter Description	<i>ip-address</i> : Indicates the bound IPv4 address. <i>ipv6-address</i> : Indicates the bound IPv6 address. <i>mac-address</i> : Indicates the bound MAC address.
Command Mode	Global configuration mode
Configuration Usage	Run this command to configure the binding relationship between an IPv4/IPv6 address and a MAC address.

↘ [Enabling the Address Binding Function](#)

Command	address-bind install
Parameter Description	N/A
Command Mode	Global configuration mode
Configuration Usage	Run this command to enable the global IP-MAC binding function. This function is used to control forwarding of IPv4 or IPv6 packets.

↘ [Configuring a Logging Filter of Global IP-MAC Binding](#)

Command	address-bind binding-filter logging [<i>rate-limit rate</i>]
Parameter Description	rate-limit rate : Indicates the printing rate of logging filter of global IPv4-MAC binding.
Command Mode	Global configuration mode
Configuration Usage	By default, the rate is 10 logs per minute. When a logging filter is configured, alert logs are printed if IP packets not containing matched IP address and MAC address are detected. When a logging filter is configured, the number of non-printed logs is prompted if the actual printing rate exceeds the set rate.

Configuration Example

➤ **Configuring Global IP-MAC Binding and Enabling Address Binding**

Configuration Steps	<ul style="list-style-type: none"> ● Configure a global IPv4-MAC binding. ● Enable the address binding function.
	<pre>Nodexon# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)# address-bind 192.168.5.1 00d0.f800.0001 Nodexon(config)# address-bind install</pre>
Verification	Display the global IP-MAC binding on the device.
	<pre>Nodexon#show address-bind Total Bind Addresses in System : 1 IP Address Binding MAC Addr ----- 192.168.5.1 00d0.f800.0001</pre>

7.4.2 Configuring the IPv6 Address Binding Mode

Configuration Effect

- Change the IPv6 address binding mode so as to change the forwarding rules for IPv6 packets.

Configuration Steps

➤ **Configuring the IPv6 Address Binding Mode**

- (Optional) Perform this configuration when you want to change the forwarding rules for IPv6 packets.

Verification

- Run the **show run** command to check whether the configuration takes effect.

Related Commands

➤ **Configuring the IPv6 Address Binding Mode**

Command	address-bind ipv6-mode { compatible loose strict }
Parameter Description	<p>compatible: Indicates the Compatible mode.</p> <p>loose: Indicates the Loose mode.</p> <p>strict: Indicates the strict mode.</p>
Command Mode	Global configuration mode
Configuration	N/A

Usage	
--------------	--

Configuration Example

Configuring the IPv6 Address Binding Mode

Configuration Steps	<ul style="list-style-type: none"> Configure a global IP-MAC binding. Enable the address binding function. Set the IPv6 address binding mode to Compatible.
	<pre>Nodexon# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)# address-bind 192.168.5.1 00d0.f800.0001 Nodexon(config)# address-bind install Nodexon(config)# address-bind ipv6-mode compatible</pre>
Verification	Run the show run command to display the configuration on the device.

7.4.3 Configuring the Exclude Port

Configuration Effect

- The address binding function is disabled on the exclude port, and all IP packets can be forwarded.

Notes

- The configuration can be performed only on a switching port or an L2 aggregate port.

Configuration Steps

Configuring the Exclude Port

- (Optional) Perform this configuration in global configuration mode when you want to disable the address binding function on a specified port.

Verification

Run the **show run** or **show address-bind uplink** command to check whether the configuration takes effect.

Related Commands

Configuring the Exclude Port

Command Syntax	address-bind uplink <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Indicates the ID of a switching port or an L2 aggregate port.

Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Configuring the Exclude Port

Configuration Steps	<ul style="list-style-type: none"> ● Create a global IPv4-MAC binding. ● Enable the address binding function. ● Configure an exclude port.
	<pre>Nodexon# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)# address-bind 192.168.5.1 00d0.f800.0001 Nodexon(config)# address-bind install Nodexon(config)# address-bind uplink GigabitEthernet 0/1</pre>
Verification	Display the global IP-MAC binding on the device.
	<pre>Nodexon#show address-bind Total Bind Addresses in System : 1 IP Address Binding MAC Addr ----- 192.168.5.1 00d0.f800.0001 Nodexon#show address-bind uplink Port State ----- Gi0/1 Enabled Default Disabled</pre>

Displaying

Description	Command
Displays the IP-MAC binding on the device.	show address-bind
Displays the exclude port.	show address-bind uplink

8 Configuring Password Policy

8.1 Overview

The Password Policy is a password security function provided for local authentication of the device. It is configured to control users' login passwords and login states.

i The following sections introduce password policy only.

Protocols and Standards

N/A

8.2 Features

Basic Concepts

↘ **Minimum Password Length**

Administrators can set a minimum length for user passwords according to system security requirements. If the password input by a user is shorter than the minimum password length, the system does not allow the user to set this password but displays a prompt, asking the user to specify another password of an appropriate length.

↘ **Strong Password Detection**

The less complex a password is, the more likely it is to crack the password. For example, a password that is the same as the corresponding account or a simple password that contains only characters or digits may be easily cracked. For the sake of security, administrators can enable the strong password detection function to ensure that the passwords set by users are highly complex. After the strong password detection function is enabled, a prompt will be displayed for the following types of passwords:

1. Passwords that are the same as corresponding accounts;
2. Simple passwords that contain characters or digits only.

↘ **Mandatory Modification of Weak Passwords**

By default, weak passwords are configurable. However, after this function is enabled, weak passwords have to be modified to strong ones, or the configuration fails. Weak passwords meet at least one of the following conditions:

1. Passwords that are the same as corresponding accounts;
2. Simple passwords that contain characters or digits only.

↘ **Password Life Cycle**

The password life cycle defines the validity time of a user password. When the service time of a password exceeds the life cycle, the user needs to change the password.

If the user inputs a password that has already expired during login, the system will give a prompt, indicating that the password has expired and the user needs to reset the password. If the new password input during password resetting does not meet system requirements or the new passwords consecutively input twice are not the same, the system will ask the user to input the new password once again.

↘ **Guard Against Repeated Use of Passwords**

When changing the password, the user will set a new password while the old password will be recorded as the user's history records. If the new password input by the user has been used previously, the system gives an error prompt and asks the user to specify another password.

The maximum number of password history records per user can be configured. When the number of password history records of a user is greater than the maximum number configured for this user, the new password history record will overwrite the user's oldest password history record.

↘ **Storage of Encrypted Passwords**

Administrators can enable the storage of encrypted passwords for security consideration. When administrators run the **show running-config** command to display configuration or run the **write** command to save configuration files, various user-set passwords are displayed in the cipher text format. If administrators disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.

8.3 Configuration

Configuration	Description and Command	
Configuring the Password Security Policy	 Optional configuration, which is used to configure a combination of parameters related to the password security policy.	
	password policy life-cycle	Configures the password life cycle.
	password policy min-size	Configures the minimum length of user passwords.
	password policy no-repeat-times	Sets the no-repeat times of latest password configuration, so that the passwords specified in these times of latest password configuration can no longer be used in future password configuration.
	password policy strong	Enables the strong password detection function.
	password policy forced-password-modify	Enables mandatory modification of weak passwords.
	service password-encryption	Sets the storage of encrypted passwords.

Networking Requirements

- Provide a password security policy for local authentication of the device. Users can configure different password security policies to implement password security management.

Notes

- The configured password security policy is valid for global passwords (configured using the commands **enable password** and **enable secret**) and local user passwords (configured using the **username name password password** command). It is invalid for passwords in Line mode.

Configuration Steps

▾ Configuring the Password Life Cycle

- Optional
- Perform this configuration on each device that requires the configuration of a password life cycle unless otherwise stated.

▾ Configuring the Minimum Length of User Passwords

- Optional
- Perform this configuration on each device that requires a limit on the minimum length of user passwords unless otherwise stated.

▾ Setting the No-Repeat Times of Latest Password Configuration

- Optional
- Perform this configuration on each device that requires a limit on the no-repeat times of latest password configuration unless otherwise stated.

▾ Enabling Mandatory Modification of Weak Passwords

- Optional
- Do not perform this configuration on each device unless otherwise stated.

▾ Enabling the Strong Password Detection Function

- Optional
- Perform this configuration on each device that requires strong password detection unless otherwise stated.

▾ Setting the Storage of Encrypted Passwords

- Optional
- Perform this configuration on each device that requires the storage of passwords in encrypted format unless otherwise stated.

Verification

Configure a local user on the device, and configure a valid password and an invalid password for the user.

- When you configure the valid password, the device correctly adds the password.
- When you configure the invalid password, the device displays a corresponding error log.

Related Commands

▾ Configuring the Password Life Cycle

Command Syntax	password policy life-cycle <i>days</i>
Parameter Description	life-cycle <i>days</i> : Indicates the password life cycle in the unit of days. The value range is from 1 to 65535.
Command Mode	Global configuration mode
Usage Guide	The password life cycle is used to define the validity period of user passwords. If the user logs in with a password whose service time already exceeds the life cycle, a prompt is given, asking the user to change the password.

▾ Configuring the Minimum Length of User Passwords

Command Syntax	password policy min-size <i>length</i>
Parameter Description	min-size <i>length</i> : Indicates the minimum length of passwords. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the minimum length of passwords. If the minimum length of passwords is not configured, users can input a password of any length.

▾ Setting the No-Repeat Times of Latest Password Configuration

Command Syntax	password policy no-repeat-times <i>times</i>
Parameter Description	no-repeat-times <i>times</i> : Indicates the no-repeat times of latest password configuration. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, all old passwords used in the several times of latest password configuration will be recorded as the user's password history records. If the new password input by the user has been used previously, the system gives an error prompt and the password modification fails. You can configure the maximum number of password history records per user. When the number of password history records of a user is greater than the maximum number configured for the user, the new

	password history record will overwrite the user's oldest password history record.
--	---

▾ Enabling Mandatory Modification of Weak Passwords

Command Syntax	password policy forced-password-modify
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After mandatory modification of weak passwords is enabled, users have to change their passwords if the passwords are the same as corresponding accounts or contain characters or digits only.

▾ Enabling the Strong Password Detection Function

Command Syntax	password policy strong
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	<p>After the strong password detection function is enabled, a prompt is displayed for the following types of passwords:</p> <ol style="list-style-type: none"> 4. Passwords that are the same as corresponding accounts; 5. Simple passwords that contain characters or digits only.

▾ Setting the Storage of Encrypted Passwords

Command Syntax	service password-encryption
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	<p>Before the storage of encrypted passwords is set, all passwords used in the configuration process will be displayed and stored in plaintext format, unless the passwords are configured in cipher text format. You can enable the storage of encrypted passwords for security consideration. When you run the show running-config command to display configuration or run the write command to save configuration files, various user-set passwords are displayed in the cipher text format. If you disable the storage of encrypted passwords next time, the passwords already in cipher text format will not be restored to plaintext passwords.</p>

▾ Checking User-Configured Password Security Policy Information

Command Syntax	show password policy
Parameter Description	-
Command Mode	Privileged EXEC mode/ Global configuration mode/ Interface configuration mode
Usage Guide	Use this command to display the password security policy configured on the device.

↘ **Checking Information Such as the Default Password Dictionary and Weak Passwords Manually Set**

Command Syntax	show password policy
Parameter Description	-
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display information such as the default password dictionary and weak passwords manually set on the device.

Configuration Examples

i The following configuration example describes configuration related to a password security policy.

↘ **Configuring Password Security Check on the Device**

Typical Application	<p>Assume that the following password security requirements arise in a network environment:</p> <ol style="list-style-type: none"> 1. The minimum length of passwords is 8 characters; 2. The password life cycle is 90 days; 3. Passwords are stored and transmitted in cipher text format; 4. The number of no-repeat times of password history records is 3; 5. Passwords shall not be the same as user names, and shall not contain simple characters or digits only. 6. Mandatory modification of weak passwords is enabled.
Configuration Steps	<ul style="list-style-type: none"> ● Set the minimum length of passwords to 8. ● Set the password life cycle to 90 days. ● Enable the storage of encrypted passwords. ● Set the no-repeat times of password history records to 3. ● Enable the strong password detection function. ● Enable mandatory modification of weak passwords. <pre>Nodexon# configure terminal Nodexon(config)# password policy min-size 8 Nodexon(config)# password policy life-cycle 90 Nodexon(config)# service password-encryption</pre>

	<pre>Nodexon(config)# password policy no-repeat-times 3 Nodexon(config)# password policy strongNodexon (config)#password policy forced-password-modify</pre>
Verification	<p>When you create a user and the corresponding password after configuring the password security policy, the system will perform relevant detection according to the password security policy.</p> <ul style="list-style-type: none"> ● Run the show password policy command to display user-configured password security policy information. <pre>Nodexon# show password policy Global password policy configurations: Password encryption: Enabled Password strong-check: Enabled Password forced-password-modify Enabled Password secret-dictionary-check: Enabled Password min-size: Enabled (8 characters) Password life-cycle: Enabled (90 days) Password no-repeat-times: Enabled (max history record: 3)</pre>

Common Errors

- The time configured for giving a pre-warning notice about password expiry to the user is greater than the password life cycle.

8.4 Monitoring

Displaying

Command	Function
show password policy	Displays user-configured password security policy information.

9 Configuring Port Security

9.1 Overview

Port security is used to restrict access to a port. Source MAC addresses of packets can be used to restrict the packets that enter the ports of a switch. You can set the number of static MAC addresses or the number of MAC addresses that are dynamically learned to restrict the packets that can enter the port. Ports enabled with port security are called secure ports.

9.2 Applications

Application	Description
Allowing Only Specified Hosts to Use Ports	For network security, certain ports of a device can be used only by specified hosts.

9.2.1 Allowing Only Specified Hosts to Use Ports

Scenario

In a scenario that has requirements for the network security, devices cannot be completely isolated physically. In this case, the devices need to be configured to restrict the PCs that connected to the ports of the devices.

- Only specified PCs can connect to the ports and normally use the network.
- Other PCs cannot use the network even if connected to the ports.
- After the configuration is complete, the administrator does not need to perform regular maintenance.

Figure 9-1

Remarks	S is the access device. A is a PC that can use the port F0/1. B is an unknown PC.
----------------	---

Deployment

- Enable ARP Check for port F0/1 (omitted).
- Enable port security on access device S and set the violation handling mode to protect.
- Set the maximum number of secure addresses allowed by port F0/1 to 1.
- Configure a static port security address on the port F0/1.

9.3 Features

Basic Concepts

Secure Port

Ports configured with port security are called secure ports. At present, Nodexon devices require that secure ports cannot be destination ports of mirroring.

Secure Addresses

Addresses bound to secure ports are called secure addresses. Secure addresses can be layer-2 addresses, namely MAC addresses, and can also be layer-3 addresses, namely, IP or IP+MAC addresses. When a secure address is bound to IP+MAC and a static secure MAC address is configured, the static secure MAC address must be the same as the MAC address bound to IP+MAC; otherwise, communication may fail due to inconsistency with the binding. Similarly, if only IP binding is set, only packets whose secure MAC addresses are statically configured or learned and whose source IP addresses are the bound IP address can enter the device.

Dynamic Binding

A method for a device to automatically learn addresses and convert learned addresses into secure addresses.

Static Binding

A command for manually binding secure addresses.

Aging of Secure Addresses

Regularly delete secure address records. Secure addresses for port security support aging configuration. You can specify only dynamically learned addresses for aging or specify both statically configured and dynamically learned secure addresses for aging.

Sticky MAC Address

Convert dynamically learned secure addresses into statically configured addresses. Addresses will not age. After the configurations are saved, dynamic secure addresses will not be learned again upon restart. If this function is not enabled, the secure MAC addresses dynamically learned must be learned again after device restart.

Security Violation Events

When the number of learned MAC addresses learned by a port exceeds the maximum number of secure addresses, security violation events will be triggered. You can configure the following modes for handling security violation events:

- **protect**: When security violation occurs, a corresponding secure port will stop learning MAC addresses and discard all packets of newly accessed users. This is the default mode for handling violation.
- **restrict**: When violation occurs, a port violation trap notification will be sent in addition to the behavior in the protect mode.
- **shutdown**: When violation occurs, the port will be disabled in addition to the behaviors in the preceding two modes.

↘ **Maximum Number of Secure Addresses**

The maximum number of secure addresses indicates the total number of secure addresses statically configured and dynamically learned. When the number of secure addresses under a secure port does not reach the maximum number of secure addresses, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. If new users access the secure port in this case, security violation events will occur.

Overview

Feature	Description
Enabling Port Security	Creates a secure address list for a port.
Filtering Layer-2 Users	Processes the packets received by a port from non-secure addresses.
Filtering Layer-3 Users	Checks the layer-2 and layer-3 addresses of packets passing a port.
Aging of Secure Addresses	Regularly deletes secure addresses.

9.3.1 Enabling Port Security

Enable port security for a port to restrict packets that access the network through the port.

Working Principle

When port security is enabled, the device security module will check the sources of received packets. Only packets from addresses in the secure address list can be normally forwarded; otherwise, the packets will be discarded or the port performs other violation handling behaviors.

When the port security and 802.1x are configured at the same time, packets can enter a switch only when the MAC addresses of the packets meet the static MAC address configurations of 802.1x or port security. If a port is configured with a secure channel or is bound to global IP+MAC, packets in compliance with the secure channel or bound to global IP+MAC can avoid checking of port security.

Related Configuration

↘ **Enabling Port Security for a Port**

By default, port security is disabled.

You can run the **switchport port-security** command to enable or disable the port security function for a port.

You cannot enable this function for a destination port of SPAN.

▾ Setting the Maximum Number of Secure Addresses for a Port

By default, the maximum number of secure addresses for a port is 128.

You can run the **switchport port-security maximum** command to adjust the maximum number of secure addresses for the port.

A smaller number of secure addresses mean fewer users that access the network through this port.

▾ Setting the Mode for Handling Violation

By default, when the number of secure addresses reaches the maximum number, the secure port will discard packets from unknown addresses (none of the secure addresses of the port).

You can run the **switchport port-security violation** command to modify the violation handling mode.

▾ Setting Secure Addresses That Can Be Dynamically Saved

By default, no secure address dynamically learned will be saved.

You can run the **switchport port-security mac-address sticky** command to save dynamically learned addresses to the configuration file. As long as the configuration file is saved, the device does not need to re-learn the secure addresses after the device is restarted.

9.3.2 Filtering Layer-2 Users

Set the secure addresses on a port to ensure that only devices whose MAC addresses are the same as the secure addresses can access the network through this port.

Working Principle

Add secure addresses for a secure port. When the number of secure addresses for a secure port does not reach the maximum number, the secure port can dynamically learn new dynamic secure addresses. When the number of secure addresses for the secure port reaches the maximum number, the secure port will not learn dynamic secure addresses any longer. The MAC addresses of users connecting to this port must be in the secure address list; otherwise, violation events will be triggered.

Related Configuration

▾ Adding Secure Addresses for a Secure port

By default, a port dynamically learns secure addresses. If an administrator has special requirements, the administrator can manually configure secure addresses.

You can run the **switch portport-security interface** command to add or delete secure addresses for a device.

9.3.3 Filtering Layer-3 Users

Add binding of secure addresses and check layer-2 and layer-3 addresses of packets passing a port.

Working Principle

Layer-3 secure addresses support only IP binding and IP+MAC binding, and supports only static binding (not dynamic binding).

When a layer-3 secure port receives packets, layer-2 and layer-3 addresses need to be parsed. Only packets whose addresses are bound are valid packets. Other packets are considered as invalid packets and will be discarded, but no violation event will be triggered.

Related Configuration

Configuring Binding of Secure Addresses on Secure Ports

Binding of layer-3 secure addresses must be added manually.

You can run the **switchport port-security binding** command to add binding of secure addresses.

If only IP addresses are input, only IP addresses are bound. If IP addresses and MAC addresses are input, IP+MAC will be bound.

9.3.4 Aging of Secure Addresses

Regularly delete secure addresses. When this function is enabled, you need to set the maximum number of secure addresses. In this way, the device can automatically add and delete secure addresses on this port.

Working Principle

Enable the aging timer to regularly query and delete secure addresses whose aging time expires.

Related Configuration

Configuring Aging Time of Secure Addresses

By default, no secure address of a port will be aged.

You can run the **switchport port-security aging** command to enable aging time.

The **static** parameter can be used to age static addresses.

9.4 Configuration

Configuration	Description and Command
Configuring Secure ports and Violation Handling Modes	 (Mandatory) It is used to enable the port security service.
	switchport port-security Enables port security.

	switchport port-security maximum	Sets the maximum number of secure addresses for a port.
	switchport port-security violation	Configures the violation handling mode for port security.
	switchport port-security mac-address sticky	Configures automatic saving of dynamic addresses.
Configuring Secure Addresses on Secure Ports	 (Optional) It is used to configure security filtering items.	
	switchport port-security mac-address	Configures the static secure addresses in the interface configuration mode.
	switchport port-security interface mac-address	Configures the static secure addresses in the global configuration mode.
	switchport port-security binding	Configures binding of secure addresses in the interface configuration mode.
	switchport port-security interface binding	Configures binding of secure addresses in the global configuration mode.
	switchport port-security aging	Configures aging time for all secure addresses on a port.
	switchport port-security binding-filter logging	Enables binding filter logging in the global configuration mode.

9.4.1 Configuring Secure ports and Violation Handling Modes

Configuration Effect

- Restrict the number of MAC addresses that can be learned from a port.
- Filter invalid packets based on MAC addresses, IP addresses or IP+MAC.

Notes

- A secure port cannot be the destination port of SPAN.
- The port security function cannot be configured for a DHCP Snooping trusted port.
- The port security function cannot be configured for excluded ports of global IP+MAC.
- The security function can be enabled only for wired switching ports and layer-2 AP ports in the interface configuration mode.
- The port security can work with other access control functions such as the 802.1x, global IP+MAC binding, and IP source guard. When these functions are used together, packets can enter a switch only when passing all security checks. If a security channel is configured for a port, packets in compliance with the security channel will avoid checking of the port security.

Configuration Steps

▾ Enabling the Port Security Service

- Mandatory.
- If there is no special requirement, enable the port security service for a port on the access device.

▾ Configuring the Maximum Number of Secure Addresses for a Port

- Optional. To adjust the maximum number of secure addresses running on a secure port, you can configure this item.
- Configure this item on a port enabled with port security.

▾ Configuring Violation Handling Modes

- Optional. If you hope that other handling modes except discarding packets are implemented in case of violation, you can configure other handling modes.
- Configure this item on a port enabled with port security.

▾ Saving Dynamically Learned Addresses

- Optional. If you hope that secure addresses are not re-learned after the device is restarted, you can configure this item.
- Configure this item on a port enabled with port security.

Verification

Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

Related Commands

▾ Setting Port Security

Command	switchport port-security
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	By using the port security feature, you can strictly control the input of a port of a device by restricting the MAC addresses and IP addresses (optional) that access the port.

▾ Setting the Maximum Number of Secure Addresses for a Port

Command	switchport port-security maximum <i>value</i>
Parameter Description	<i>value</i> : Indicates the number of secure addresses, ranging from 1 to 128.
Command Mode	Interface configuration mode
Usage Guide	If you set the maximum number to 1 and configure a secure address for this port, the workstation (whose

	address is the configured secure address) connected to this port will exclusively use all bandwidth of the port.
--	--

↘ Configuring the Violation Handling Mode for Port Security

Command	switchport port-security violation { protect restrict shutdown }
Parameter	protect: Discards violated packets.
Description	restrict: Discards violated packets and send trap notifications. shutdown: Discards packets and disables the port.
Command Mode	Interface configuration mode
Usage Guide	-

↘ Saving Dynamic Secure Addresses to a Configuration File

Command	switchport port-security mac-address sticky mac-address [vlan vlan-id]
Parameter	<i>mac-address:</i> Indicates a static secure address.
Description	<i>vlan-id:</i> Indicates the VID of a MAC address.
Command Mode	Interface configuration mode
Usage Guide	-

Configuration Example

↘ Enabling Port Security for the Port gigabitethernet 0/3, Setting the Maximum Number of Addresses to 8, and Setting the Violation Handling Mode to protect

Configuration Steps	<ul style="list-style-type: none"> ● Enable port security. ● Set the maximum number of secure addresses. ● Modify the violation handling mode.
	<pre>Nodexon# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Nodexon(config)# interface gigabitethernet 0/3 Nodexon(config-if-GigabitEthernet 0/3)# switchport mode access Nodexon(config-if-GigabitEthernet 0/3)# switchport port-security Nodexon(config-if-GigabitEthernet 0/3)# switchport port-security maximum 8 Nodexon(config-if-GigabitEthernet 0/3)# switchport port-security violation protect Nodexon(config-if-GigabitEthernet 0/3)# switchport port-security mac-address sticky</pre>
	<pre>Nodexon(config-if-GigabitEthernet 0/3)# end</pre>
Verification	Check the port security configuration on the device.

```
Nodexon# show port-security interface gigabitethernet
0/3

Interface : Gi0/3

Port Security: Enabled

Port status : down

Violation mode: Protect

Maximum MAC Addresses:8

Total MAC Addresses:0

Configured MAC Addresses:0

Aging time : 0 mins

SecureStatic address aging : Disabled
```

Common Errors

- Port security is enabled on a SPAN port.
- Port security is enabled on a DHCP trusted port.
- The configured maximum number of secure addresses is smaller than the number of existing secure addresses.

9.4.2 Configuring Secure Addresses on Secure Ports

Configuration Effect

- Allow specified users to use ports.
- Regularly update secure addresses of users.

Notes

- Sticky MAC addresses are special MAC addresses not affected by the aging mechanism. No matter dynamic or static aging is configured, sticky MAC addresses will not be aged.

Configuration Steps

▾ Configuring Secure Addresses

- Optional. You need to manually add secure addresses for configuration.
- Configure this item on a port enabled with port security.

▾ Configuring Binding of Secure Addresses

- Optional. You need to add layer-3 secure addresses for configuration.
- Configure this item on a port enabled with port security.

▾ Configuring Aging Time

- Optional.
- Configure this item on a port enabled with port security.

▾ Enabling Binding Filter Logging

- Optional.
- Enable binding filter logging in the global configuration mode.

Verification

- Run the command of the device for displaying the port security configurations to check whether the configurations take effect.

Related Commands

▾ Adding Secure Addresses for Secure Ports in the Global Configuration Mode

Command	switchport port-security interface <i>interface-id</i> mac-address <i>mac-address</i> [vlan <i>vlan-id</i>]
Parameter	<i>interface-id</i> : Indicates the interface ID.
Description	<i>mac-address</i> : Indicates a static secure address. <i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Global configuration mode
Usage Guide	-

▾ Adding Secure Addresses for Secure Ports in the Interface Configuration Mode

Command	switchportport-security mac-address <i>mac-address</i> [vlan <i>vlan_id</i>]
Parameter	<i>mac-address</i> : Indicates a static secure address.
Description	<i>vlan-id</i> : Indicates the VID of a MAC address.
Command Mode	Interface configuration mode
Usage Guide	-

▾ Adding Binding of Secure Addresses for Secure Ports in the Global Configuration Mode

Command	switchport port-security interface <i>interface-id</i> binding [<i>mac-address</i> vlan <i>vlan_id</i>] { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter	<i>interface-id</i> : Indicates the interface ID.
Description	<i>mac-address</i> : Indicates a bound source MAC address. <i>vlan_id</i> : Indicates the VID of a bound source MAC address. <i>ipv4-address</i> : Indicates a bound IPv4 address. <i>ipv6-address</i> : Indicates a bound IPv6 address.
Command Mode	Global configuration mode

Usage Guide	-
--------------------	---

➤ Adding Binding of Secure Addresses for Secure Ports in the Interface Configuration Mode

Command	switchport port-security binding [<i>mac-address</i> vlan <i>vlan_id</i>] { <i>ipv4-address</i> <i>ipv6-address</i> }
Parameter Description	<i>mac-address</i> : Indicates a bound source MAC address. <i>vlan_id</i> : Indicates the VID of a bound source MAC address. <i>ipv4-address</i> : Indicates a bound IPv4 address. <i>ipv6-address</i> : Indicates a bound IPv6 address.
Command Mode	Interface configuration mode
Usage Guide	-

➤ Configuring Aging Time for All Secure Addresses on a Port

Command	switchport port-security aging { static time <i>time</i> }
Parameter Description	static : Indicates that the aging time will be applied to manually configured secure addresses and automatically learned addresses; otherwise, the aging time will be applied to only automatically learned addresses. time <i>time</i> : Indicates the aging time of the secure addresses on this port, ranging from 0 to 1440 minutes. If it is set to 0, it indicates that the aging function is disabled actually.
Command Mode	Interface configuration mode
Usage Guide	-

➤ Enabling Binding Filter Logging

Command	switchport port-security binding-filter logging [rate-limit <i>rate</i>]
Parameter Description	rate-limit <i>rate</i> : Indicates the printing rate of binding filter logging.
Command Mode	Global configuration mode
Usage Guide	<ol style="list-style-type: none"> 1. If you run the switchport port-security binding-filter logging command without configuring the <i>rate</i> parameter, binding filter logging is enabled and the default printing rate, 10logs/minute, is adopted. 2. After binding filter logging is enabled, for packets that do not comply with IP/IP-MAC binding, warnings are printed. 3. After binding filter logging is enabled, if the printing rate exceeds the configured rate, the number of suppressed packets is displayed.

Displays all valid secure addresses of ports and the security binding records of the ports.	show port-security all
Displays the port security configurations of an interface.	show port-security interface <i>interface-id</i>
Displays the statistics about port security.	show port-security

10 Configuring Storm Control

10.1 Overview

When a local area network (LAN) has excess broadcast data flows, multicast data flows, or unknown unicast data flows, the network speed will slow down and packet transmission will have an increased timeout probability. This situation is called a LAN storm. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast data flows, multicast data flows, or unknown unicast data flows. If the rate of data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds. This prevents flood data from entering the LAN causing a storm.

10.2 Applications

Application	Description
Network Attack Prevention	Enable storm control to prevent flooding.

10.2.1 Network Attack Prevention

Scenario

The application requirements of network attack prevention are described as follows:

- Protect devices from flooding of broadcast packets, multicast packets, or unknown unicast packets.

Figure 10-1

Remarks	Switch A and Switch B are access devices. PC 1, PC 2, PC 3, and PC 4 are desktop computers.
----------------	--

Deployment

- Enable storm control on the ports of all access devices (Switch A and Switch B).

10.3 Features

Basic Concepts

Storm Control

If the rate of data flows (broadcast packets, multicast packets, or unknown unicast packets) received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Storm Control Based on the Bandwidth Threshold

If the rate of data flows received by a device port is within the configured bandwidth threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Storm Control Based on the Packets-per-Second Threshold

If the rate of data flows received by a device port is within the configured packets-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Storm Control Based on the Kilobits-per-Second Threshold

If the rate of data flows received by a device port is within the configured kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the threshold, excess data flows are discarded until the rate falls within the threshold.

Overview

Feature	Description
Unicast Packet Storm Control	Limits unknown unicast packets to prevent flooding.
Multicast Packet Storm Control	Limits multicast packets to prevent flooding.
Broadcast Packet Storm Control	Limits broadcast packets to prevent flooding.

10.3.1 Unicast Packet Storm Control

The unicast packet storm control feature monitors the rate of unknown unicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of unknown unicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ **Enabling Unicast Packet Storm Control on Ports**

By default, unicast packet storm control is disabled on ports.

Run the **storm-control unicast** [{ **level** *percent* | **pps** *packets* | *rate-bps* }] command to enable unicast packet storm control on ports.

Run the **no storm-control unicast** or **default storm-control unicast** command to disable unicast packet storm control on ports.

The default command parameters are determined by related products.

10.3.2 Multicast Packet Storm Control

The multicast packet storm control feature monitors the rate of multicast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of multicast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ **Enabling Multicast Packet Storm Control on Ports**

By default, multicast packet storm control is disabled on ports.

Run the **storm-control multicast** [{ **level** *percent* | **pps** *packets* | *rate-bps* }] command to enable multicast packet storm control on ports.

Run the **no storm-control multicast** or **default storm-control multicast** command to disable multicast packet storm control on ports.

The default command parameters are determined by related products.

10.3.3 Broadcast Packet Storm Control

The broadcast packet storm control feature monitors the rate of broadcast data flows received by a device port to limit LAN traffic and prevent flooding caused by excess data flows.

Working Principle

If the rate of broadcast data flows received by a device port is within the configured bandwidth threshold, packets-per-second threshold, or kilobits-per-second threshold, the data flows are permitted to pass through. If the rate exceeds the thresholds, excess data flows are discarded until the rate falls within the thresholds.

Related Configuration

↳ Enabling Broadcast Packet Storm Control on Ports

By default, broadcast packet storm control is disabled on ports.

Run the **storm-control broadcast** [{ **level** *percent* | **pps** *packets* | *rate-bps* }] command to enable broadcast packet storm control on ports.

Run the **no storm-control broadcast** or **default storm-control broadcast** command to disable broadcast packet storm control on ports.

10.4 Configuration

Configuration	Description and Command
Configuring Basic Functions of Storm Control	 (Mandatory) It is used to enable storm control.
	storm-control { broadcast multicast unicast } [{ level <i>percent</i> pps <i>packets</i> <i>rate-bps</i> }] Enables storm control.

10.4.1 Configuring Basic Functions of Storm Control

Configuration Effect

- Prevent flooding caused by excess broadcast packets, multicast packets, and unknown unicast packets.

Notes

- When you run a command (for example, **storm-control unicast**) to enable storm control, if you do not set the parameters, the default values are used.

Configuration Steps

↳ Enabling Unicast Packet Storm Control

- Mandatory.
- Enable unicast packet storm control on every device unless otherwise specified.

↳ Enabling Multicast Packet Storm Control

- Mandatory.
- Enable multicast packet storm control on every device unless otherwise specified.

▾ Enabling Broadcast Packet Storm Control

- Mandatory.
- Enable broadcast packet storm control on every device unless otherwise specified.

Verification

- Run the **show storm-control** command to check whether the configuration is successful.

Related Commands

▾ Enabling Unicast Packet Storm Control

Command	storm-control unicast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

▾ Enabling Multicast Packet Storm Control

Command	storm-control multicast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

▾ Enabling Broadcast Packet Storm Control

Command	storm-control broadcast [{ level percent pps packets <i>rate-bps</i> }]
Parameter	level percent : Indicates the bandwidth percentage.
Description	pps packets : Indicates the number of packets per second. <i>rate-bps</i> : Indicates the packet rate.
Command Mode	Interface configuration mode
Usage Guide	Storm control can be enabled only on switch ports.

Configuration Example

▾ Enabling Storm Control on Devices

Scenario	
-----------------	--

<p>Figure 10-2</p>																										
<p>Configuration Step</p>	<ul style="list-style-type: none"> ● Enable storm control on Switch A and Switch B.

11 Configuring SSH

11.1 Overview

Secure Shell (SSH) connection is similar to a Telnet connection except that all data transmitted over SSH is encrypted. When a user in an insecure network environment logs into a device remotely, SSH helps ensure information security and powerful authentication, protecting the device against attacks such as IP address spoofing and plain-text password interception.

An SSH-capable device can be connected to multiple SSH clients. In addition, the device can also function as an SSH client, and allows users to set up an SSH connection with a SSH-server device. In this way, the local device can safely log in to a remote device through SSH to implement management.

-  Currently, a device can work as either the SSH server or an SSH client, supporting SSHv1 and SSHv2 versions. Nodexon SSH service supports both IPv4 and IPv6.
-  Unless otherwise specified, SSH in this document refers to SSHv2.

Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3
- draft-ietf-secsh-filexfer-05: SSH File Transfer Protocol
- draft-ylonen-ssh-protocol-00: The version of the SSH Remote Login Protocol is 1.5. Comware implements the SSH server functions, but not the SSH client functions.

11.2 Applications

Application	Description
SSH Device Management	Use SSH to manage devices.
SSH Local Line Authentication	Use the local line password authentication for SSH user authentication.

Application	Description
SSH AAA Authentication	Use the authentication, authorization and accounting (AAA) mode for SSH user authentication.
SSH Public Key Authentication	Use the public key authentication for SSH user authentication.
SSH File Transfer	Use the Secure Copy (SCP) commands on the client to exchange data with the SSH server.
SSH Client Application	Use the SSH client to safely log in to a remote device for management.

11.2.1 SSH Device Management

Scenario

You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows system does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the configurations of the SSH client. Figure 11-1 shows the network topology.

Figure 11-1 Networking Topology of SSH Device Management

Deployment

Configure the SSH client as follows:

- Start the PuTTY software.
- On the **Session** option tab of PuTTY, type in the host IP address of the SSH server and SSH port number **22**, and select the connection type **SSH**.
- On the **SSH** option tab of PuTTY, select the preferred SSH protocol version **2**.
- On the **SSH authentication** option tab of PuTTY, select the authentication method **Attempt "keyboard-interactive" auth**.
- Click **Open** to connect to the SSH server.
- Type in the correct user name and password to enter the terminal login interface.

11.2.2 SSH Local Line Authentication

Scenario

SSH clients can use the local line password authentication mode, as shown in Figure 11-2. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server function is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.

Figure 11-2 Networking Topology of SSH Local Line Password Authentication

Deployment

- Configure the SSH server as follows:
 1. Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.
 2. Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH clients, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses an RSA key, whereas SSHv2 adopts an RSA or DSA key.
 3. Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server using this IP address. The routes from the SSH clients to the SSH server are reachable.
- Configure the SSH client as follows:
 1. Diversified SSH client software is available, including PuTTY, Linux, and OpenSSH. This document takes PuTTY as an example to explain the method for configuring the SSH clients.
 2. Open the PuTTY connection tab, and select SSHv1 for authenticated login. (The method is similar if SSHv2 is selected.)
 3. Set the IP address and connected port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22. Click **Open** to start the connection. As the current authentication mode does not require a user name, you can type in any user name, but cannot be null. (In this example, the user name is "anyname".)

11.2.3 SSH AAA Authentication

Scenario

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 11-3. To ensure security of data exchange, the PCs function as the SSH clients, and uses the SSH protocol to log in to the network device where the SSH

server is enabled. To better perform security management, the AAA authentication mode is used for user login on the SSH clients. Two authentication methods, including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, it turns to the local authentication.

Figure 11-3 Networking Topology of SSH AAA Authentication

Deployment

- The routes from the SSH clients to the SSH server are reachable, and the route from the SSH server to the Radius server is also reachable.
- Configure the SSH server on the network device that functions as an SSH client.
- Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.

11.2.4 SSH Public Key Authentication

Scenario

SSH clients can use the public keys for authentication, and the public key algorithm can be RSA or DSA, as shown in Figure 11-4. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.

Figure 11-4 Network Topology for Public Key Authentication of SSH Users

Deployment

- To implement public key authentication for the client, generate a key pair (RSA or DSA) on the client, configure the public key on the SSH server, and select the public key authentication mode.

- After the key is generated on the client, the SSH server will copy the file of the public key from the client to the flash and associates the file with the SSH user name. Each user can be associated with one RSA public key and one DSA public key.

11.2.5 SSH File Transfer

Scenario

The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server, as shown in Figure 11-5.

Figure 11-5 Networking Topology of SSH File Transfer

Deployment

- Enable the SCP service on the server.
- On the client, use SCP commands to upload files to the server, or download files from the server.

11.2.6 SSH Client Application

Scenario

The SSH service is enabled on a remote SSH server, and the **ssh** command is used on the local client to set up an SSH connection with the server for secure data transmission, as shown in Figure 11-6.

Figure 11-6 Networking Topology of SSH Client Application

Deployment

- Enable the SSH service on the server.
- On the client, run the **ssh** command to set up an SSH connection with the server for secure data transmission.

11.3 Features

Basic Concepts

▾ User Authentication Mechanism

- Password authentication

During the password authentication, a client sends a user authentication request and encrypted user name and password to the server. The server decrypts the received information, compares the decrypted information with those stored on the server, and then returns a message indicating the successful or unsuccessful authentication.

- Public key authentication

During the public key authentication, digital signature algorithms, such as RSA and DSA, are used to authenticate a client. The client sends a public key authentication request to the server. This request contains information including the user name, public key, and public key algorithm. On receiving the request, the server checks whether the public key is correct. If wrong, the server directly sends an authentication failure message. If right, the server performs digital signature authentication on the client, and returns a message indicating the successful or unsuccessful authentication.

 Public key authentication is applicable only to the SSHv2 clients.

SSH Communication

To ensure secure communication, interaction between an SSH server and an SSH client undergoes the following seven stages:

- Connection setup

The server listens on Port 22 to the connection request from the client. After originating a socket initial connection request, the client sets up a TCP socket connection with the server.

- Version negotiation

If the connection is set up successfully, the server sends a version negotiation packet to the client. On receiving the packet, the client analyzes the packet and returns a selected protocol version to the server. The server analyzes the received information to determine whether version negotiation is successful.

- Key exchange and algorithm negotiation

If version negotiation is successful, key exchange and the algorithm negotiation are performed. The server and the client exchange the algorithm negotiation packet with each other, and determine the final algorithm based on their capacity. In addition, the server and the client work together to generate a session key and a session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

After the encrypted channel is set up, the client sends an authentication request to the server. The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

After the successful authentication, the client sends a session request to the server. The server waits and processes the client request. After the session request is successfully processed, SSH enters the session interaction stage.

- Session interaction

After the session request is successfully processed, SSH enters the session interaction stage. Encrypted data can be transmitted and processed in both directions. The client sends a command to be executed to the client. The server decrypts, analyzes, and processes the received command, and then sends the encrypted execution result to the client. The client decrypts the execution result.

- Session ending

When the interaction between the server and the client is terminated, the socket connection disconnects, and the session ends.

Overview

Feature	Description
SSH Server	Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client.
SCP Service	After the SCP service is enabled, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.
SSH Client	You can use the SSH client on the device to set up a secure connection with the SSH server on a network device.

11.3.1 SSH Server

Enable the SSH server function on a network device, and you can set up a secure connection with the network device through the SSH client. You can also shut down the SSH server function to disconnect from all SSH clients.

Working Principle

For details about the working principle of the SSH server, see the "SSH Communication" in "Basic Concepts." In practice, after enabling the SSH server function, you can configure the following parameters according to the application requirements:

- Version: Configure the SSH version as SSHv1 or SSHv2 to connect SSH clients.
- Authentication timeout: The SSH server starts the timer after receiving a user connection request. The SSH server is disconnected from the client either when the authentication succeeds or when the authentication timeout is reached.
- Maximum number of authentication retries: The SSH server starts authenticating the client after receiving its connection request. If authentication does not succeed when the maximum number of user authentication retries is reached, a message is sent, indicating the authentication failure.
- Public key authentication: The public key algorithm can be RSA or DSA. It provides a secure connection between the client and the server. The public key file on the client is associated with the user name. In addition, the public key authentication mode is configured on the client, and the corresponding private key file is specified. In this way, when the client attempts to log in to the server, public key authentication can be implemented to set up a secure connection.

Related Configuration

▾ Enabling the SSH Server

By default, the SSH server is disabled.

In global configuration mode, run the **[no] enable service ssh-server** command to enable or disable the SSH server.

To generate the SSH key, you also need to enable the SSH server.

▾ Specifying the SSH Version

By default, the SSH server supports both SSHv1 and SSHv2, connecting either SSHv1 clients or SSHv2 clients.

Run the **ip ssh version** command to configure the SSH version supported by the SSH server.

If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

▾ Configuring the SSH Authentication Timeout

By default, the user authentication timeout is 120s.

Run the **ip ssh time-out** command to configure the user authentication timeout of the SSH server. Use the **no** form of the command to restore the default timeout. The SSH server starts the timer after receiving a user connection request. If authentication does not succeed before the timeout is reached, authentication times out and fails.

▾ Configuring the Maximum Number of SSH Authentication Retries

By default, the maximum number of user authentication retries is 3.

Run the **ip ssh authentication-retries** command to configure the maximum number of user authentication retries on the SSH server. Use the **no** form of the command to restore the default number of user authentication retries. If authentication still does not succeed when the maximum number of user authentication retries is reached, user authentication fails.

▾ Specifying the SSH Encryption Mode

By default, the encryption mode supported by the SSH server is Compatible, that is, supporting cipher block chaining (CBC), counter (CTR) and other encryption modes.

Run the **ip ssh cipher-mode** command to configure the encryption mode supported by the SSH server. Use the **no** form of the command to restore the default encryption mode supported by the SSH server.

▾ Specifying the SSH Message Authentication Algorithm

By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5,SHA1,SHA1-96, and MD5-96, are supported.

Run the **ip ssh hmac-algorithm** command to configure the message authentication algorithm supported by the SSH server. Use the **no** form of the command to restore the default message authentication algorithm supported by the SSH server.

▾ Setting A Monitoring Port ID for the SSH Server

The default port ID is 22.

Run the **ip ssh port** command to set a monitoring port ID for the SSH server. Use either the **no ip ssh port** command or the **ip ssh port 22** command to restore the default setting.

▾ Enabling the Public Key Authentication on the SSH Server

Run the **ip ssh peer** command to associate the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

11.3.2 SCP Service

The SSH server provides the SCP service to implement secure file transfer between the server and the client.

Working Principle

- SCP is a protocol that supports online file transfer. It runs on Port 22 based on the BSC RCP protocol, whereas RCP provides the encryption and authentication functions based on the SSH protocol. RCP implements file transfer, and SSH implements authentication and encryption.
- Assume that the SCP service is enabled on the server. When you use an SCP client to upload or download files, the SCP client first analyzes the command parameters, sets up a connection with a remote server, and starts another SCP process based on this connection. This process may run in source or sink mode. (The process running in source mode is the data provider. The process running in sink mode is the destination of data.) The process running in source mode reads and sends files to the peer end through the SSH connection. The process running in sink mode receives files through the SSH connection.

Related Configuration

↳ Enabling the SCP Server

By default, the SCP server function is disabled.

Run the **ip scp server enable** command to enable SCP server function on a network device.

11.3.3 SSH Client

The SSH client is used to set up a secure connection with a remote network device on which the SSH server runs.

Working Principle

For details about the working principle of the SSH client, see the "SSH Communication" in "Basic Concepts."

Related Configuration

↳ Specifying the Source Interface of the SSH Client

By default, the source address of SSH packets is searched based on the destination address.

Run the **ip ssh source-interface** *interface-name* command to specify the source interface of the SSH client.

↳ Establishing a Session with the SSH Server

Run the **ssh** command to log in to a remote device that supports the SSH Server

↳ Recovering an Established SSH Session

- Run the **ssh-session** *session-id* command to recover an established SSH session.

Disconnecting a Suspended SSH Session

- Run the **disconnect ssh-session** *session-id* command to disconnect a specified SSH session.

11.4 Configuration

Configuration	Description and Command	
Configuring the SSH Server	 It is mandatory to enable the SSH server.	
	enable service ssh-server	Enables the SSH server.
	disconnect ssh[<i>vty</i>] <i>session-id</i>	Disconnects an established SSH session.
	crypto key generate {rsa dsa}	Generates an SSH key.
	ip ssh version {1 2}	Specifies the SSH version.
	ip ssh time-out <i>time</i>	Configures the SSH authentication timeout.
	ip ssh authentication-retries <i>retry times</i>	Configures the maximum number of SSH authentication retries.
	ip ssh cipher-mode{cbc ctr others }	Specifies the SSH encryption mode.
	ip ssh hmac-algorithm{md5 md5-96 sha1 sha1-96}	Specifies the SSH message authentication algorithm.
	ip ssh peer <i>test</i> public-key rsa flash :<i>rsa.pub</i>	Associates an RSA public key file with a user.
	ip ssh peer <i>test</i> public-key dsa flash:<i>dsa.pub</i>	Associates a DSA public key file with a user.
ip ssh port <i>port</i>	Sets a monitoring port ID for the SSH server.	
Configuring the SCP Service	 Mandatory.	
	ip scp server enable	Enables the SCP server.
Configuring the SSH Client	 (Optional)It is used to set up a secure connection with a remote network device that supports the SSH server.	
	ip ssh source-interface <i>interface-name</i>	Specifies the source interface of the SSH client.
	ssh [-v { 1 2 }] [-c { 3des aes128-cbc aes192-cbc aes256-cbc }] [-l <i>username</i>] [-m { hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }] [-p <i>port-num</i>] { <i>ip-addr</i> <i>hostname</i> } [/source { <i>ip A.B.C.D</i> <i>ipv6 X:X:X:X::X</i> <i>interface interface-name</i> }] [/vrf <i>vrf-name</i>]	Establishes an encrypted session with a remote network device.

11.4.1 Configuring the SSH Server

Configuration Effect

- Enable the SSH server function on a network device so that you can set up a secure connection with a remote network device through the SSH client. All interactive data is encrypted before transmitted, featuring authentication and security.
- You can use diversified SSH user authentications modes, including local line password authentication, AAA authentication, and public key authentication.
- You can generate or delete an SSH key.
- You can specify the SSH version.
- You can configure the SSH authentication timeout.
- You can configure the maximum number of SSH authentication retries.
- You can specify the SSH encryption mode.
- You can specify the SSH message authentication algorithm.
- You can specify ACL filtering of the SSH server.

Notes

- The precondition of configuring a device as the SSH server is that communication is smooth on the network that the device resides, and the administrator can access the device management interface to configure related parameters.
- The **no crypto key generate** command does not exist. You need to run the **crypto key zeroize** command to delete a key.
- The SSH module does not support hot standby. Therefore, for products that supports hot standby on the supervisor modules, if no SSH key file exist on the new active module after failover, you must run the **crypto key generate** command to re-generate a key before using SSH.

Configuration Steps

▾ Enabling the SSH Server

- Mandatory.
- By default, the SSH server is disabled. In global configuration mode, enable the SSH server and generate an SSH key so that the SSH server state changes to ENABLE.

▾ Specifying the SSH Version

- Optional.
- By default, the SSH server supports SSHv1 and SSHv2, connecting either SSHv1 or SSHv2clients. If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

▾ Configuring the SSH Authentication Timeout

- Optional.

- By default, the SSH authentication timeout is 120s. You can configure the user authentication timeout as required. The value ranges from 1 to 120. The unit is second.

↘ **Configuring the Maximum Number of SSH Authentication Retries**

- Optional.
- Configure the maximum number of SSH authentication retries to prevent illegal behaviors such as malicious guessing. By default, the maximum number of SSH authentication retries is 3, that is, a user is allowed to enter the user name and password three times for authentication. You can configure the maximum number of retries as required. The value ranges from 0 to 5.

↘ **Specifying the SSH Encryption Mode**

- Optional.
- Specify the encryption mode supported by the SSH server. By default, the encryption mode supported by the SSH server is Compatible, that is, supporting CBC, CTR and other encryption modes.

↘ **Specifying the SSH Message Authentication Algorithm**

- Optional.
- Specify the message authentication algorithm supported by the SSH server. By default, the message authentication algorithms supported by the SSH server are as follows: (1) For the SSHv1, no algorithm is supported; (2) For the SSHv2, four algorithms, including MD5, SHA1, SHA1-96, and MD5-96, are supported.

↘ **Setting ACL Filtering of the SSH Server**

- Optional.
- Set ACL filtering of the SSH server. By default, ACL filtering is not performed for all connections to the SSH server. According to needs, set ACL filtering to perform for all connections to the SSH server.

↘ **Enabling the Public Key Authentication for SSH Users**

- Optional.
- Only SSHv2 supports authentication based on the public key. This configuration associates a public key file on the client with a user name. When a client is authenticated upon login, a public key file is specified based on the user name.

Verification

- Run the **show ip ssh** command to display the current SSH version, authentication timeout, and maximum number of authentication retries of the SSH server.
- Run the **show crypto key mypubkey** command to display the public information of the public key to verify whether the key has been generated.
- Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

Related Commands

↳ Enabling the SSH Server

Command	enable service ssh-server
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	To disable the SSH server, run the no enable service ssh-server command in global configuration mode. After this command is executed, the SSH server state changes to DISABLE.

↳ Disconnecting an Established SSH Session

Command	disconnect ssh[<i>vty</i>] <i>session-id</i>
Parameter	vty: Indicates an established virtual teletype terminal (VTY) session.
Description	<i>session-id:</i> Indicates the ID of the established SSH session. The value ranges from 0 to 35.
Command Mode	Privileged EXEC mode
Usage Guide	Specify an SSH session ID to disconnect the established SSH session. Alternatively, specify a VTY session ID to disconnect a specified SSH session. Only an SSH session can be disconnected.

↳ Generating an SSH Key

Command	crypto key generate {rsa dsa}
Parameter	rsa: Generates an RSA key.
Description	dsa: Generates a DSA key.
Command Mode	Global configuration mode
Usage Guide	The no crypto key generate command does not exist. You need to run the crypto key zeroize command to delete a key. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. If an RSA key is generated, both SSHv1 and SSHv2 are supported. If only a DSA key is generated, only SSHv2 can use the key.

↳ Specifying the SSH Version

Command	ip ssh version {1 2}
Parameter	1: Indicates that the SSH server only receives the connection requests sent by SSHv1 clients.
Description	2: Indicates that the SSH server only receives the connection requests sent by SSHv2 clients.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh version command to restore the default settings. By default, the SSH server supports both SSHv1 and SSHv2.

↘ Configuring the SSH Authentication Timeout

Command	ip ssh time-out <i>time</i>
Parameter Description	<i>time</i> : Indicates the SSH authentication timeout. The value ranges from 1 to 120. The unit is second.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh time-out command to restore the default SSH authentication timeout, which is 120s.

↘ Configuring the Maximum Number of SSH Authentication Retries

Command	ip ssh authentication-retries <i>retry times</i>
Parameter Description	<i>retry times</i> : Indicates the maximum number of user authentication retries. The value ranges from 0 to 5.
Command Mode	Global configuration mode
Usage Guide	Run the no ip ssh authentication-retries command to restore the default number of user authentication retries, which is 3.

↘ Specifying the SSH Encryption Mode
