Command	ip ssh cipher-mode {cbc ctr others }
Parameter Description	<p>cbc: Sets the encryption mode supported by the SSH server to the CBC mode. Corresponding algorithms include DES-CBC,3DES-CBC,AES-128-CBC,AES-192-CBC,AES-256-CBC, and Blowfish-CBC.</p> <p>ctr: Sets the encryption mode supported by the SSH server to the CTR mode. Corresponding algorithms include AES128-CTR, AES192-CTR, and AES256-CTR.</p> <p>others: Sets the encryption mode supported by the SSH server to others. The corresponding algorithm is RC4.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is used to configure the encryption mode supported by the SSH server.</p> <p>On Nodexon devices, the SSHv1 server supports the DES-CBC, 3DES-CBC, and Blowfish-CBC encryption algorithms; the SSHv2 server supports the AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC,3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4 encryption algorithms. These algorithms can be grouped into three encryption modes: CBC, CTR, and others.</p> <p>As the cryptography continuously develops, it is approved that encryption algorithms in the CBC and others modes can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption mode supported by the SSH server to CTR to increase the security level of the SSH server.</p>

↘ Specifying the SSH Message Authentication Algorithm

Command	ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96}
Parameter	md5 : Indicates that the message authentication algorithm supported by the SSH server is MD5.

Description	md5-96: Indicates that the message authentication algorithm supported by the SSH server is MD5-96. sha1: Indicates that the message authentication algorithm supported by the SSH server is SHA1. sha1-96: Indicates that the message authentication algorithm supported by the SSH server is SHA1-96.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the message authentication algorithm supported by the SSH server. On Nodexon devices, the SSHv1 server does not support any message authentication algorithm; the SSHv2 server supports the MD5, SHA1, SHA1-96, and MD5-96 message authentication algorithms. You can select message authentication algorithms supported by the SSH server as required.

↘ Setting A Monitoring Port ID for the SSH Server

Command	ip ssh port <i>port</i>
Parameter Description	<i>port</i> : Indicates the monitoring port ID of the SSH server. The value ranges from 1025 to 65535.
Command Mode	Global configuration mode
Usage Guide	Use either the no ip ssh port or the ip ssh port 22 to restore the monitoring port ID of the SSH server to the default value.

↘ Configuring RSA Public Key Authentication

Command	ip ssh peer <i>test</i> public-key rsaflash: <i>rsa.pub</i>
Parameter Description	<i>test</i> : Indicates the user name. rsa : Indicates that the public key type is RSA. <i>rsa.pub</i> : Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the RSA public key file associated with user <i>test</i> . Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

↘ Configuring DSA Public Key Authentication

Command	ip ssh peer <i>test</i> public-key dsaflash: <i>dsa.pub</i>
Parameter Description	<i>test</i> : Indicates the user name. dsa : Indicates that the public key type is DSA. <i>dsa.pub</i> : Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the DSA key file associated with user <i>test</i> . Only SSHv2 supports authentication based on the public key. This command associates the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified

	based on the user name.
--	-------------------------

Configuration Example

i The following configuration examples describe only configurations related to SSH.

Generating a Public Key on the SSH Server

Configuration Steps	<ul style="list-style-type: none"> Run the crypto key generate { rsa dsa } command to generate a RSA public key for the server.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)# crypto key generate rsa Choose the size of the rsa key modulus in the range of 512 to 2048 and the size of the dsa key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]:</pre> <ul style="list-style-type: none"> If the generation of the RSA key is successful, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ...[ok] % Generating 512 bit RSA keys ...[ok]</pre> If the generation of the RSA key fails, the following information is displayed: <pre>% Generating 512 bit RSA1 keys ...[fail] % Generating 512 bit RSA keys ...[fail]</pre>
Verification	<ul style="list-style-type: none"> Run the show crypto key mypubkey rsa command to display the public information about the RSA key. If the public information about the RSA key exists, the RSA key has been generated.
SSH Server	<pre>Nodexon(config)#show crypto key mypubkey rsa % Key pair was generated at: 1:49:47 UTC Jan 4 2013 Key name: RSA1 private Usage: SSH Purpose Key Key is not exportable. ```

➤ **Specifying the SSH Version**

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh version { 1 2 } command to set the version supported by the SSH server to SSHv2.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)#ip ssh version 2</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the SSH version currently supported by the SSH server.
SSH Server	<pre>Nodexon(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

➤ **Configuring the SSH Authentication Timeout**

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh time-out <i>time</i> command to set the SSH authentication timeout to 100s.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)#ip sshtime-out100</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the configured SSH authentication timeout.
SSH Server	<pre>Nodexon(config)#show ip ssh SSH Enable - version 2.0</pre>

	Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled
--	---

▾ Configuring the Maximum Number of SSH Authentication Retries

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh authentication-retries <i>retry times</i> command to set the maximum number of user authentication retries on the SSH server to 2.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)#ip ssh authentication-retries 2</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to display the configured maximum number of authentication retries.
SSH Server	<pre>Nodexon(config)#show ip ssh SSH Enable - version 2.0 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

▾ Specifying the SSH Encryption Mode

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh cipher-mode {cbc ctr others} command to set the encryption mode supported by the SSH server to CTR.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)# ip ssh cipher-mode ctr</pre>
Verification	<ul style="list-style-type: none"> Select the CTR encryption mode on the SSH client, and verify whether you can successfully log in to the SSH server from the SSH client.

▾ Specifying the SSH Message Authentication Algorithm

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh hmac-algorithm {md5 md5-96 sha1 sha1-96} command to set the message authentication algorithm supported by the SSH server to SHA1.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)# ip ssh hmac-algorithmsha1</pre>
Verification	<ul style="list-style-type: none"> Select the SHA1 message authentication algorithm on the SSH client, and verify whether you can successfully log in to the SSH server from the SSH client.

▾ Setting A Monitoring Port ID for the SSH Server

Configuration Steps	<ul style="list-style-type: none"> Run the <code>ip ssh port port</code> command to set a monitoring port ID to 10000.
SSH Server	<pre>Nodexon# configure terminal Nodexon(config)# ip ssh port 10000</pre>
Verification	<ul style="list-style-type: none"> Run the <code>show ip ssh</code> command to display information about a monitoring port ID for the SSH server. <pre>Nodexon(config)#show ip ssh SSH Enable - version 2.0 SSH Port: 10000 SSH Cipher Mode: cbc,ctr,others SSH HMAC Algorithm: md5-96,md5,sha1-96,sha1 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: disabled</pre>

📌 **Configuring the Public Key Authentication**

Configuration Steps	<ul style="list-style-type: none"> Run the <code>ip ssh peer username public-key { rsa dsa }filename</code> command to associate a public key file of the client with a user name. When the client is authenticated upon login, a public key file (for example, RSA) is specified based on the user name.
SSH Server	<pre>Nodexon#configure terminal Nodexon(config)# ip ssh peer test public-key rsaflash:rsa.pub</pre>
Verification	<ul style="list-style-type: none"> Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If yes, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

📌 **Configuring SSH Device Management**

<p>Scenario Figure11- 7</p>	 <p>SSH Client 192.168.23.83 IP Network SSH Server 192.168.23.122</p> <p>You can use SSH to manage devices on the precondition that the SSH server function is enabled. By default, this function is disabled. The Telnet component that comes with the Windows does not support SSH. Therefore, a third-party client software must be used. Currently, well-compatible client software includes PuTTY, Linux, and SecureCRT. The following takes the PuTTY as an example to introduce the</p>
--	---

configurations of the SSH client.

Configuration Steps

- Start the PuTTY software.
- On the **Session** option tab of PuTTY, type in the host IP address **192.168.23.122** and SSH port number **22**, and select the connection type **SSH**.
- On the **SSH** option tab of PuTTY, select the preferred SSH protocol version **2**.
- On the **SSH authentication** option tab of PuTTY, select the authentication method **Attempt "keyboard-interactive" auth**.
- Click **Open** to connect to the SSH server.
- Type in the correct user name and password to enter the terminal login interface.

SSH Client

Figure 11-8

Host Name (or IP address) indicates the IP address of the host to be logged in. In this example, the IP address is **192.168.23.122**. **Port** indicates the port ID 22, that is, the default ID of the port listened by SSH. **Connection type** is **SSH**.

Figure 11-9

As shown in Figure 11-9, select **2** as the preferred SSH protocol version in the **Protocol options** pane because SSHv2 is used for login.

Figure 11-10

As shown in Figure 11-10, select **Attempt "keyboard-interactive" auth** as the authentication method to support authentication based on the user name and password.

Then, click **Open** to connect to the configured server host, as shown in Figure 11-10.

Figure 11-11

The **PuTTY Security Alert** box indicates that you are logging in to the client of the server 192.168.23.122, and asks you whether to receive the key sent from the server.

If you select **Yes**, a login dialog box is displayed, as shown in Figure 11-11.

Figure 11-12

Type in the correct user name and password, and you can log in to the SSH terminal interface, as shown in Figure 11-12.

Figure 11-13

- Verification**
- Run the **show ip ssh** command to display the configurations that are currently effective on the SSH server.
 - Run the **show ssh** command to display information about every SSH connection that has been established.

```
Nodexon#show ip ssh
SSH Enable - version 1.99
Authentication timeout: 120 secs
Authentication retries: 3
Nodexon#show ssh
Connection Version Encryption      Hmac      State      Username
          0      2.0 aes256-cbc      hmac-sha1  Session started test
```

↘ [Configuring SSH Local Line Authentication](#)

Scenario
Figure 11-14

SSH users can use the local line password for user authentication, as shown in Figure 11-14. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Any user name can be used.

Configuration Steps

Configure the SSH server as follows:

- Enable the SSH server function globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.
- Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses the RSA key, whereas SSHv2 uses the RSA or DSA key.
- Configure the IP address of the FastEthernet 0/1 interface on the SSH server. The SSH client is connected to the SSH server based on this IP address. The route from the SSH client to the SSH server is reachable.

Configure the SSH client as follows:

- Diversified SSH client software is available, including PuTTY, Linux, and SecureCRT. This document takes PuTTY as an example to explain the method for configuring the SSH client. For details about the configuration method, see "Configuration Steps."

SSH Server

Before configuring SSH-related function, ensure that the route from the SSH user to the network segment of the SSH server is reachable. The interface IP address configurations are shown in Figure 11-14. The detailed procedures for configuring IP addresses and routes are omitted.

```
Nodexon(config)# enable service ssh-server
Nodexon(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:
Choose the size of the key modulus in the range of 360 to 2048 for your
```

	<p>Signature Keys. Choosing a key modulus greater than 512 may take a few minutes.</p> <p>How many bits in the modulus [512]:</p> <p>% Generating 512 bit RSA1 keys ...[ok]</p> <p>% Generating 512 bit RSA keys ...[ok]</p> <p>Nodexon(config)#interface fastEthernet0/1</p> <p>Nodexon(config-if-fastEthernet0/1)#ip address 192.168.23.122 255.255.255.0</p> <p>Nodexon(config-if-fastEthernet0/1)#exit</p> <p>Nodexon(config)#line vty 0</p> <p>Nodexon(config-line)#password passzero</p> <p>Nodexon(config-line)#privilege level 15</p> <p>Nodexon(config-line)#login</p> <p>Nodexon(config-line)#exit</p> <p>Nodexon(config)#line vty1 4</p> <p>Nodexon(config-line)#password pass</p> <p>Nodexon(config-line)#privilege level 15</p> <p>Nodexon(config-line)#login</p> <p>Nodexon(config-line)#exit</p>
SSH Client(PC1/PC2)	Figure 11-15

Set the IP address and port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22 (For details about the configuration method, see "Configuring SSH Device Management."). Click **Open** to start the SSH server. As the current authentication mode does not require a user name, you can type in any user name, but cannot leave the user name unspecified. (In this example, the user name is "anyname".)

Verification

- Run the **show running-config** command to display the current configurations.
- Verify that the SSH client configurations are correct.

SSH Server

```
Nodexon#show running-configBuilding
configuration...!
enable secret 5 $1$eyy2$xs28FDw4s2q0tx97
enable service ssh-server
!
interface fastEthernet0/1
ip address 192.168.23.122 255.255.255.0
!
line vty 0
privilege level 15
```

```
login
password passzero
line vty 1 4
privilege level 15
login
password pass
!
end
```

SSH Client

Set up a connection, and enter the correct password. The login password is "passzero" for Line 0 and "pass" for the remaining lines. Then, the SSH server operation interface is displayed, as shown in Figure 11-16.

Figure 11-16

```
Nodexon#show users
```

Line	User	Host(s)	Idle	Location
* 0 con 0	---	idle	00:00:00	---
1 vty 0	---	idle	00:08:02	192.168.23.83
2 vty 1	---	idle	00:00:58	192.168.23.121

➤ [Configuring AAA Authentication of SSH Users](#)

Scenario
Figure 11-17

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 11-17. To ensure security of data exchange, the PC functions as the SSH client, and uses the SSH protocol to log in to the network device where the SSH server is enabled. To better perform security management, the AAA authentication mode is used on the user login interface of the SSH client. Two authentication methods, including Radius server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The Radius server authentication method is preferred. If the Radius server does not respond, select the local authentication method.

Configuration Steps

- The route from the SSH client to the SSH server is reachable, and the route from the SSH server to the Radius server is also reachable.
- Configure the SSH server on the network device. The configuration method is already described in the previous example, and therefore omitted here.
- Configure the AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.

SSH Server

```
Nodexon(config)# enable service ssh-server
Nodexon(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:
Choose the size of the key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
% Generating 512 bit RSA1 keys ...[ok]
% Generating 512 bit RSA keys ...[ok]
```

	<pre> Nodexon(config)#crypto key generate dsa Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit DSA keys ...[ok] Nodexon(config)#interface gigabitEthernet1/1 Nodexon(config-if-gigabitEthernet1/1)#ip address 192.168.217.81 255.255.255.0 Nodexon(config-if-gigabitEthernet1/1)#exit Nodexon#configure terminal Nodexon(config)#aaa new-model Nodexon(config)#radius-server host 192.168.32.120 Nodexon(config)#radius-server key aaradius Nodexon(config)#aaa authentication login methodgroup radius local Nodexon(config)#line vty 0 4 Nodexon(config-line)#login authentication method Nodexon(config-line)#exit Nodexon(config)#username user1 privilege 1 password 111 Nodexon(config)#username user2 privilege 10 password 222 Nodexon(config)#username user3 privilege 15 password 333 Nodexon(config)#enable secret w </pre>
Verification	<ul style="list-style-type: none"> ● Run the show running-config command to display the current configurations. ● This example assumes that the SAM server is used. ● Set up a remote SSH connection on the PC. ● Check the login user.
	<pre> Nodexon#show run aaa new-model ! aaa authentication login method group radius local ! username user1 password 111 </pre>

```

username user2 password 222

!
line con 0
line vty 0 4
  login authentication method
!
End

```

On the SSH client, choose **System Management>Device Management**, and add the device IP address **192.168.217.81** and the device key **aaaradius**.

Choose **Security Management>Device Management Rights**, and set the rights of the login user.

Choose **Security Management>Device Administrator**, and add the user name **user** and password **pass**.

Configure the SSH client and set up a connection to the SSH server. For details, see the previous example.

Type in the user name **user** and password **pass**. Verify that you can log in to the SSH server successfully.

```
Nodexon#show users
```

Line	User	Host(s)	Idle	Location
0 con 0		idle	00:00:31	
* 1 vty 0	user	idle	00:00:33	192.168.217.60

↘ Configuring Public Key Authentication of SSH Users

<p>Scenario Figure 11-18</p>	 <p>SSH Client 192.168.23.83</p> <p>IP Network</p> <p>SSH Server 192.168.23.122</p> <p>SSH users can use the public key for user authentication, and the public key algorithm is RSA or DSA, as shown in Figure 11-18. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● To implement public key authentication on the client, generate a key pair (for example, RSA key) on the client, place the public key on the SSH server, and select the public key authentication mode. <hr/> <p>i After the key pair is generated on the client, you must save and upload the public key file to the server and complete the server-related settings before you can continue to configure the client and connect the client with the server.</p> <hr/> <ul style="list-style-type: none"> ● After the key is generated on the client, copy the public key file from the client to the flash of the SSH server, and associate the file with an SSH user name. A user can be associated with one RSA public key and one DSA public key.
<p>SSH Client</p>	<p>Run the puttygen.exe software on the client. Select SSH-2 RSA in the Parameters pane, and click Generate to generate a key, as shown in Figure 11-19.</p> <p>Figure 11-19</p>

When a key is being generated, you need to constantly move the mouse over a blank area outside the green progress bar; otherwise, the progress bar does not move and key generation stops, as shown in Figure 11-20.

Figure 11-20

To ensure security of the RSA public key authentication, the length of the generated RSA key pair must be equal to or larger than 768 bits. In this example, the length is set to 1024 bits.

Figure 11-21

After the key pair is generated, click **Save public key**, type in the public key name **test_key.pub**, select the storage path, and click **Save**. Then click **Save private key**. The following prompt box is displayed. Select **Yes**, type in the public key name **test_private**, and click **Save**.

Figure 11-22

You must select the OpenSSH key file; otherwise, the key file cannot be used. The **puttygen.exe** software can be used to generate a key file in OpenSSH format, but this file cannot be directly used by the PuTTY client. You must use **puttygen.exe** to convert the private key to the PuTTY format. Format conversion is not required for the public key file stored on the server, and the format of this file is still OpenSSH, as shown in Figure 11-23.

Figure 11-23

	
<p>SSH Server</p>	<pre>Nodexon#configure terminal Nodexon(config)# ip ssh peer test public-key rsaflash: test_key.pub</pre>
<p>Verification</p>	<ul style="list-style-type: none"> After completing the basic configurations of the client and the server, specify the private key file test_private on the PuTTY client, and set the host IP address to 192.168.23.122 and port ID to 22 to set up a connection between the client and the server. In this way, the client can use the public key authentication mode to log in to the network device.
	<p>Figure 11-24</p>

Common Errors

- The `no crypto key generate` command is used to delete a key.

11.4.2 Configuring the SCP Service

Configuration Effect

After the SCP function is enabled on a network device, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, featuring authentication and security.

Notes

- The SSH server must be enabled in advance.

Configuration Steps

▾ Enabling the SCP Server

- Mandatory.
- By default, the SCP server function is disabled. Run the `ip scp server enable` command to enable the SCP server function in global configuration mode.

Verification

Run the **show ip ssh** command to check whether the SCP server function is enabled.

Related Commands

↳ Enabling the SCP Server

Command	ip scp server enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to enable the SCP server. Run the no ip scp server enable command to disable the SCP server.

Configuration Example

↳ Enabling the SCP Server

Configuration Steps	<ul style="list-style-type: none"> Run the ip scp server enable command to enable the SCP server. <pre>Nodexon#configure terminal Nodexon(config)#ip scp server enable</pre>
Verification	<ul style="list-style-type: none"> Run the show ip ssh command to check whether the SCP server function is enabled. <pre>Nodexon(config)#show ipssh SSH Enable - version 1.99 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: enabled</pre>

↳ Configuring SSH File Transfer

Scenario Figure 11-25	 <p>The diagram illustrates a network setup for SSH file transfer. On the left, an icon of a laptop represents the 'SSH Client' with IP address 192.168.23.83. A line connects it to a central cloud icon representing the 'IP Network'. Another line connects the cloud to a server rack icon representing the 'SSH Server' with IP address 192.168.23.122.</p>
	<p>The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server.</p>
Configuration	<ul style="list-style-type: none"> Enable the SCP service on the server.

<p>Steps</p>	<p>i The SCP server uses SSH threading. 11.4.3 Configuring the SSH Client

Configuration Effect

On the network device that supports the SSH server, enable the SSH server function, and specify the user authentication method and supported SSH versions. Then, you can use the built-in SSH client function of the device to set up a secure connection with the SSH server, implementing remote device management.

Notes

- The SSH server function must be configured in advance on the device that needs to remotely support the SSH server.
- The SSH client must communicate with the SSH server properly.

Configuration Steps

↘ Specifying the Source Interface of the SSH Client

- (Optional) This configuration must be performed on the SSH-client device.

↘ Establishing a Session with the SSH Server

- (Optional) Use the **ssh** command on the client to set up a connection with a remote server.
- Before using this command, enable the SSH server function and configure the SSH key and authentication mode on the server.

↘ Recovering an Established SSH Session

- (Optional) Run the related command to recover a session after temporary stop if necessary.

↘ Disconnecting a Suspended SSH Session

- (Optional) This configuration must be performed on the SSH client if you need to disconnect a specified SSH session.

Verification

Run the **show ssh-session** command to display information about every established SSH client session.

Related Commands

↘ Specifying the Source Interface of the SSH Client

Command	ip ssh source-interface <i>interface-name</i>
Parameter	<i>interface-name</i> : Specifies an interface, the IP address of which will be used as the source address of an SSH client session.
Description	SSH client session.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify an interface, the IP address of which will be used as the global source address of an SSH client session. When the ssh command is used to connect to an SSH server, this global configuration will be used if a source interface or a source address is not specified for this connection. Run the no ip ssh source-interface command to restore the default setting.

↘ Establishing a Session with the SSH Server

Command	<code>ssh [oob] [-v {1 2}][-c {3des aes128-cbc aes192-cbc aes256-cbc }] [-l username][-m {hmac-md5-96 hmac-md5-128 hmac-sha1-96 hmac-sha1-160 }] [-p port-num][ip-add hostname][via mgmt-name][/source {ip A.B.C.D ipv6 X:X:X:X interface interface-name}] [/vrf vrf-name]</code>
Parameter Description	N/A
Command Mode	User EXEC mode
Usage Guide	<p>The ssh command is used to set up a secure and encrypted connection from the local device (an SSH client) to another device (an SSH server) or any other server that supports SSHv1 or SSHv2. This connection provides a mechanism similar to the Telnet connection except that all data transmitted over this connection is encrypted. Based on authentication and encryption, the SSH client can set up a secure connection on an insecure network.</p> <ul style="list-style-type: none">  SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms.  SSHv2 supports the following Advanced Encryption Standards (AES):AES128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, and AES256-CTR.  SSHv1 does not support the Hashed Message Authentication Code (HMAC).  If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is set up.

↘ Recovering an Established SSH Client Session

Command	<code>ssh-session session-id</code>
Parameter Description	<i>session-id</i> : Indicates the ID of an established SSH client session.
Command Mode	User EXEC mode
Usage Guide	This command is used to restore the use of an established SSH client session. When the ssh command is used to initiate an SSH client session, you can press Ctrl+Shift+6+X to temporarily exit the session. To recover this session, run the ssh-session command. In addition, if the session is already established, you can run the show ssh-session command to display information about the established session.

↘ Disconnecting a Suspended SSH Session

Command	<code>disconnect ssh-session session-id</code>
Parameter Description	<i>session-id</i> : Indicates the ID of a suspended SSH client session.
Command Mode	User EXEC mode
Usage Guide	You can specify an SSH client session ID to disconnect the specified SSH client session.

Configuration Example

➤ **Specifying the Source Interface of the SSH Client**

Configuration Steps	<ul style="list-style-type: none"> Run the ip ssh source-interface <i>interface-name</i> command to specify an interface, the IP address of which will be used as the global source address of an SSH client session.
	<pre>Nodexon#configure terminal Nodexon(config)#ipsshsource-interface gigabitEthernet 0/1</pre>
Verification	N/A

➤ **Establishing a Session with the SSH Server**

Scenario Figure 11-26	 <p>The SSH server function is enabled on the server. The ssh command is used on the client to set up a secure connection with the server.</p>
Configuration Steps	<ul style="list-style-type: none"> Enable the SSH server function on the server. Configure the SSH key on the server. Configure the authentication mode of the SSH server, and use the local line authentication mode for Line 0 to Line 4. Configure the IP address of the Gi 0/1 interface of the SSH server. The client will use this address as the source address to connect to the SSH server. Configure the SSH client, and specify the source address of the SSH client. <hr/> <ul style="list-style-type: none"> i By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. i With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating the successful or unsuccessful authentication. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. i The authentication mode used by the SSH server is local line authentication. The local user name is admin, and the password is 123456. i The SSH client is connected to the SSH server based on this IP address. The routes from the SSH clients to the SSH server are reachable. i Configure the IP address of the Gi 0/1 interface of the SSH server. The client will use this address as the source address to connect to the SSH server.

11.5 Monitoring

Displaying

Description	Command
Displays the effective SSH server configurations.	show ipssh
Displays the established SSH connection.	show ssh
Displays the public information of the SSH public key.	show crypto key mypubkey
Displays the established SSH client session.	show ssh-session

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SSH sessions.	debug ssh
Debugs SSH client sessions.	debug ssh client

12 Configuring URPF

12.1 Overview

Unicast Reverse Path Forwarding (URPF) is a function that protects the network against source address spoofing.

URPF obtains the source address and inbound interface of a received packet, and searches a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. Otherwise, the packet is forwarded.

URPF is implemented in two modes:

- **Strict mode:** It is often deployed on a point-to-point (P2P) interface, and inbound and outbound data streams must go through the network of the P2P interface.
- **Loose mode:** It is applicable to the asymmetric routes or multihomed network that have the problem of asymmetric traffic.

Protocols and Standards

- RFC 2827: Network Ingress Filtering: DDOS Attacks which employ IP Source Address Spoofing
- RFC 3704: Ingress Filtering for Multi-homed Networks

12.2 Applications

Application	Description
Strict Mode	Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network.
Loose Mode	On a multihomed network, the user network is connected to multiple Internet service providers (ISPs), and the inbound and outbound traffic is not symmetric. Deploy the URPF loose mode on the outbound interface connected to ISPs to prevent invalid packets from attacking the user network.

12.2.1 Strict Mode

Scenario

An attacker initiates an attack by sending packets with the spoofed source address 11.0.0.1. As a result, the server sends a lot of SYN or ACK packets to the hosts that do not initiate the attack, and the host with the real source address 11.0.0.1 is also affected. Even worse, if the network administrator determines that this address initiates an attack to the network, and therefore blocks all data streams coming from this source address, the denial of service (DoS) of this source address occurs.

Figure 12-1

Remarks The attacker sends spoofing packets using a spoofed address of the casualty.

Deployment

- Deploy the URPF strict mode on device A to protect the device against source address spoofing.

12.2.2 Loose Mode

Scenario

The asymmetric route is a common network application used to control the network traffic or to meet the routing policy requirements.

As shown in Figure 12-2, if the URPF strict mode is enabled on the G1/1 interface of R 1, R1 receives a packet from the network segment 192.168.20.0/24 on the G1/1 interface, but the interface obtained through the URPF check is G1/2. Therefore, this packet fails in the URPF check and is dropped.

Figure 12-2

Deployment

- Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet.
- The URPF loose mode can resolve the asymmetric traffic problem of the asymmetric route and prevents access of invalid data streams.

12.3 Features

Basic Concepts

↳ URPF Strict Mode

Obtain the source address and inbound interface of a received packet, and search a forwarding entry in the forwarding table based on the source address. If the entry does not exist, the packet is dropped. If the outbound interface of the forwarding entry does not match the inbound interface of the packet, the packet is also dropped. The strict mode requires that the inbound interface of a received packet must be the outbound interface of the route entry to the source address of the packet.

↳ URPF Loose Mode

Reversely search a route based on the source IP address of a received packet. The purpose is to find a route, and it is not required that the outbound interface of the next hop on the route must be the inbound interface of the received packet. However, the route cannot be a route of a host on the local network.

↳ URPF Packet Loss Rate

The URPF packet loss rate is equal to the number of packets dropped due to the URPF check per second. The unit is packets/second, that is, pps.

↳ Calculation Interval of the URPF Packet Loss Rate

It is the interval from the previous time the packet loss rate is calculated to the current time the packet loss rate is calculated.

↳ Sampling Interval of the URPF Packet Loss Rate

It is the interval at which the number of lost packets is collected for calculating the packet loss rate. This interval must be equal to or longer than the calculation interval of the packet loss rate.

↳ Threshold of the URPF Packet Loss Rate

It refers to the maximum packet loss rate that is acceptable. When the packet loss rate exceeds the threshold, alarms can be sent to users through syslogs or trap messages. You can adjust the threshold of the packet loss rate based on the actual conditions of the network.

↳ Alarm Interval of the URPF Packet Loss Rate

It is the interval at which alarms are sent to users. You can adjust the alarm based on the actual conditions of the network to prevent frequently output of logs or trap messages.

↘ Calculation of the URPS Packet Loss Rate

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

Overview

Feature	Description
Enabling URPF	Enable URPF to perform a URPF check, thus protecting the device against source address spoofing.
Notifying the URPF Packet Loss Rate	To facilitate monitoring of information about lost packets after URPF is enabled, Nodexon devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

12.3.1 Enabling URPF

Enable URPF to perform a URPF check on IPv4 or IPv6 packets, thus protecting the device against source address spoofing.

Working Principle

URPF can be applied to IP packets based on configurations, but the following packets are not checked by URPF:

1. After URPF is enabled, the source address of a packet is checked only if the destination address of the packet is a unicast address, and is not checked if the packet is a multicast packet or an IPv4 broadcast packet.
2. If the source IP address of a DHCP/BOOTP packet is 0.0.0.0 and the destination IP address is 255.255.255.255, the packet is not checked by URPF.
3. A loopback packet sent by the local device to itself is not checked by URPF.

↘ URPF Configured in Interface Configuration Mode

URPF, including IPv4 URPF and IPv6 URPF, is performed on packets received on the configured interface. URPF configured in global configuration mode is mutually exclusive with URPF configured in interface configuration mode.

- By default, the default route is not used for the URPF check. You can configure data to use the default route for the URPF check if necessary.
- By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACL entry (ACE), the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.

- ✔ A switch supports configuration of URPF on a routed port of L3 aggregate port (AP). Some switches also support configuration of URPF on a switch virtual interface (SVI). (For details about the switch products, contact Nodexon technical

support engineers.) The following constraints exists:

- URPF does not support association with the ACL option.
- After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such a scenario, be cautious in enabling URPF.
- After URPF is enabled, the route forwarding capacity of the device will be reduced by half.
- After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode.

Related Configuration

↳ Enabling URPF for a Specified Interface

By default, URPF is disabled for a specified interface.

Run the **ip verify unicast source reachable-via** {rx | any } [**allow-default**] [*acl-name*] command to enable or disable the IPv4 or IPv6 URPF function for a specified interface.

By default, the default route is not used for the URPF check. You can use the **allow-default** keyword to use the default route for the URPF check if necessary.

By default, packets that fail in the URPF check will be dropped. If the ACL (*acl-name*) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.

12.3.2 Notifying the URPF Packet Loss Rate

To facilitate monitoring of information about lost packets after URPF is enabled, Nodexon devices support the use of syslogs and trap messages to proactively notify users of the packet loss information detected in the URPF check.

Working Principle

Between the period of time from enabling of URPF to the time that the sampling interval arrives, the packet loss rate is equal to the number of lost packets measured within the sampling interval divided by the URPF enabling duration. After that, the packet loss rate is calculated as follows: Current packet loss rate = (Current number of lost packets measured at the calculation interval – Number of lost packets measured before the sampling interval)/Sampling interval

After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Related Configuration

↳ Configuring the Calculation Interval of the URPF Packet Loss Rate

By default, the calculation interval of the URPF packet loss rate is 30s. If the calculation interval is found too short, run the **ip verify urpf drop-rate compute interval** *seconds* command to modify the calculation interval.

The calculation interval of the URPF packet loss rate ranges from 30 to 300.

↘ [Configuring the Alarm Interval of the URPF Packet Loss Rate](#)

By default, the alarm interval of the URPF packet loss rate is 300s. If the alarm interval is found inappropriate, run the **ip verify urpf drop-rate notify hold-down *seconds*** command to modify the alarm interval of the URPF packet loss rate.

The unit of the alarm interval is second. The value ranges from 30 to 300.

↘ [Configuring the Function of Monitoring the URPF Packet Loss Information](#)

By default, the function of monitoring the URPF packet loss information is disabled.

Run the **ip verify urpf drop-rate notify** command to enable or disable the function of monitoring the URPF packet loss information.

↘ [Configuring the Threshold of the URPF Packet Loss Rate](#)

By default, the threshold of the URPF packet loss rate is 1000 pps. If the threshold is found inappropriate, run the **ip verify urpf notification threshold *rate-value*** command to modify the threshold of the URPF packet loss rate.

The unit of the threshold is pps. The value ranges from 0 to 4,294,967,295.

12.4 Configuration

Configuration Item	Description and Command	
Enabling URPF	 (Mandatory) It is used to enable URPF.	
	ip unicast source reachable-via rx (Global configuration mode)	Enables URPF Globally.
	ip unicast source reachable-via { rx any } [allow-default] [<i>acl_name</i>] (Interface configuration mode)	Enables URPF for a specified interface.
Configuring the Function of Monitoring the URPF Packet Loss Information	 (Optional) It is used to enable the function of monitoring the URPF packet loss information.	
	ip verify urpf drop-rate compute interval <i>seconds</i>	Configures the calculation interval of the URPF packet loss rate.
	ip verify urpf drop-rate notify	Configures the function of monitoring URPF packet loss information.
	ip verify urpf drop-rate notify hold-down <i>seconds</i>	Configures the alarm interval of the URPF packet loss rate.
	ip erify urpf notification threshold <i>rate-value</i>	Configures the threshold of the URPF packet loss rate.

12.4.1 Enabling URPF

Configuration Effect

- Enable URPF to perform a URPF check on IP packets, thus protecting the device against source address spoofing.
- URPF enabled in interface configuration mode supports both the strict and loose modes.

Notes

- URPF is implemented with the help of the existing unicast routes on the network. Therefore, unicast routes must be configured on the network.

Configuration Steps

↳ Enabling IPv4 URPF for a Specified Interface

- Mandatory.
- IPv4 URPF configured in interface configuration mode is mutually exclusive with IPv4 URPF configured in global configuration mode.
- Switches supports configuration of IPv4 URPF on a routed port or L3 AP port, other products supports configuration of IPv4 URPF on a routed port.

Verification

Enable URPF and check the source address as follows:

- If the strict mode is used, check whether a packet is forwarded only when the forwarding table contains the source address of the received IPv4 packet and the outbound interface of the searched forwarding entry matches the inbound interface of the packet; otherwise, the packet is dropped.
- If the loose mode is used, check whether a packet is forwarded when a forwarding entry can be found in the forwarding table for the source address of the received IPv4 packet; otherwise, the packet is dropped.

Related Commands

↳ Enabling IPv4 URPF for a Specified Interface

Command	ip verify unicast source reachable-via { rx any } [allow-default] [acl-id]
Parameter Description	<p>rx: Indicates that the URPF check is implemented in strict mode. The strict mode requires that the outbound interface of the forwarding entry found in the forwarding table based on the source address of a received IP packet must match the inbound interface of the packet.</p> <p>any: Indicates that the URPF check is implemented in loose mode. The loose mode only requires that a forwarding entry can be found in the forwarding table based on the source address of a received IP packet.</p> <p>allow-default: (Optional) Indicates that the default route can be used for the URPF check.</p> <p>acl-id: (Optional) Indicates the ID of the ACL. Values include 1 to 99 (IP standard access list), 100 to 199 (IP extended access list), 1300 to 1999 (IP standard access list, expanded range), and 2000 to 2699 (IP extended access list, expanded range).</p>

Command Mode	Interface configuration mode
Usage Guide	<p>Based on the source address of a received IP packet, URPF checks whether any route to the source address exists in the forwarding table and accordingly determines whether the packet is valid. If no forwarding entry is matched, the packet is determined as invalid.</p> <p>You can enable URPF in interface configuration mode to perform a URPF check on packets received on the interface.</p> <p>By default, the default route is not used for the URPF check. You can use the allow-default keyword to use the default route for the URPF check if necessary.</p> <p>By default, packets that fail in the URPF check will be dropped. If the ACL (<i>acl-name</i>) is configured, the packet is matched against the ACL after it fails in the URPF check. If no ACL exists, or a packet matches a deny ACE, the packet will be dropped. If the packet matches a permit ACE, the packet will be forwarded.</p> <hr/> <p> A switch supports configuration of URPF on a routed port or L3 AP port. In addition, the following constraints exists:</p> <hr/> <ol style="list-style-type: none"> 1. URPF does not support association with the ACL option. 2. After URPF is enabled on interfaces, a URPF check is performed on all packets received on physical ports corresponding to these interfaces, which increase the scope of packets checked by URPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by URPF. In such a scenario, be cautious in enabling URPF. 3. After URPF is enabled, the route forwarding capacity of the device will be reduced by half. 4. After the URPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the URPF check, the packet will be processed according to the URPF loose mode. 5. If URPF is configured in global configuration mode, the default route cannot be used for the URPF check. <hr/> <p> URPF configured in global configuration mode is mutually exclusive with URPF configured in interface configuration mode.</p>

Configuration Example

↳ Configuring the Strict Mode

	<p>Block the packets with spoofed sourced addresses at the access layer or aggregation layer to prevent sending these packets from PCs to the core network.</p> <p>To meet the preceding requirement, enable URPF in strict mode on the interface between the aggregation device and the access device.</p>
--	---

Scenario
Figure 12-3

Verification

As shown in Figure 12-3, enable URPF in strict mode on the aggregation devices, including Nodexon A and Nodexon B. The configurations are as follows:

Nodexon-A

```
Nodexon-A# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Nodexon-A (config)# interface gigabitEthernet0/1
Nodexon-A (config-if-GigabitEthernet 0/1)#ip address 195.52.1.1 255.255.255.0
Nodexon-A (config-if-GigabitEthernet 0/1)#ip verify unicast source reachable-via rx
Nodexon-A (config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify
Nodexon-A (config-if-GigabitEthernet 0/1)#exit
Nodexon-A (config)# interface gigabitEthernet0/2
Nodexon-A (config-if-GigabitEthernet 0/2)#ip address 195.52.2.1 255.255.255.0
Nodexon-A (config-if-GigabitEthernet 0/2)#ip verify unicast source reachable-via rx

12.4.2 Configuring the Function of Monitoring the URPF Packet Loss Information

Configuration Effect

- After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

Notes

- URPF must be enabled.

Configuration Steps

▾ Configuring the Calculation Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

▾ Configuring the Alarm Interval of the URPF Packet Loss Rate

- Optional.
- Global configuration mode

▾ Configuring the Function of Monitoring the URPF Packet Loss Information

- Optional.
- Interface configuration mode

▾ Configuring the Threshold of the URPF Packet Loss Rate

- Optional.
- Interface configuration mode

Verification

Simulate a source address spoofing attack, enable URPF, and check as follows:

- Enable the alarm function. After the packet loss rate exceeds the threshold, check whether an alarm can be generated normally.

Related Commands

▾ Configuring the Calculation Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate compute interval <i>seconds</i>
Parameter Description	interval seconds: Indicates the calculation interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	The calculation interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based calculation of the URPF packet loss rate.

▾ Configuring the Alarm Interval of the URPF Packet Loss Rate

Command	ip verify urpf drop-rate notify hold-down <i>seconds</i>
Parameter Description	hold-down seconds: Indicates the alarm interval of the URPF packet loss rate. The unit is second. The value ranges from 30 to 300. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	The alarm interval of the URPF packet loss rate is configured in global configuration mode. The configuration is applied to the global and interface-based alarms of the URPF packet loss rate.

▾ Configuring the Function of Monitoring the IPv4 URPF Packet Loss Information

Command	ip verify urpf drop-rate notify
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	After the function of monitoring the URPF packet loss information is enabled, the device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the URPF check so that users can monitor the network status conveniently.

▾ Configuring the Threshold of the IPv4 URPF Packet Loss Rate

Command	ip verify urpf notification threshold <i>rate-value</i>
----------------	--

Parameter Description	threshold <i>rate-value</i> : Indicates the threshold of the URPF packet loss rate. The unit is pps. The value ranges from 0 to 4,294,967,295. The default value is 1,000 pps.
Command Mode	Interface configuration mode
Usage Guide	If the threshold is 0, a notification is sent for every packet that is dropped because it fails in the URPF check. You can adjust the threshold based on the actual situation of the network.

Configuration Example

Setting the Calculation Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the calculation interval of the URPF packet loss rate to 120s in global configuration mode.
	<pre>Nodexon#configure terminal Nodexon(config)# ip verify urpf drop-rate compute interval 120 Nodexon(config)# end</pre>
Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Nodexon# show ip urpf IP verify URPF drop-rate compute interval is 120s</pre>

Setting the Alarm Interval of the URPF Packet Loss Rate to 120s

Configuration Steps	Set the alarm interval of the URPF packet loss rate to 120s in global configuration mode.
	<pre>Nodexon#configure terminal Nodexon(config)# ip verify urpf drop-rate notify hold-down 120 Nodexon(config)# end</pre>
Verification	Run the show ip urpf command to check whether the configuration takes effect.
	<pre>Nodexon# show ip urpfIP verify URPF drop-rate notify hold-down is 120s</pre>

Enabling the Function of Monitoring the IPv4 URPF Packet Loss Information on the Interface GigabitEthernet 0/1

Configuration	Enable the function of monitoring the IPv4 URPF packet loss information on the interface GigabitEthernet 0/1.
	<pre>Nodexon#configure terminal Nodexon(config)# interface gigabitEthernet0/1</pre>

	<pre>Nodexon(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Nodexon(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify</pre>
Verification	Run the show ip urpf command to check whether the function of monitoring the IPv4 URPF packet loss information is enabled on the interface GigabitEthernet 0/1.
	<pre>Nodexon# show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify is enabled IP verify URPF notification threshold is 1000pps Number of drop packets in this interface is 0 Number of drop-rate notification counts in this interface is 0</pre>

📌 Setting the Threshold of the IPv4 URPF Packet Loss Rate to 2,000 pps on the Interface GigabitEthernet 0/1

Configuration	Set the threshold of the IPv4 URPF packet loss rate to 2,000 pps on the interface GigabitEthernet 0/1.
	<pre>Nodexon#configure terminal Nodexon(config)# interface gigabitEthernet0/1 Nodexon(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx Nodexon(config-if-GigabitEthernet 0/1)#ip verify urpf notification threshold 2000</pre>
Verification	Run the show ip urpf command to check the threshold of the IPv4 URPF packet loss rate and the threshold of the IPv6 URPF packet loss rate.
	<pre>Nodexon# show ip urpf interface gigabitEthernet 0/1 IP verify source reachable-via RX IP verify URPF drop-rate notify is enabled IP verify URPF notification threshold is 2000pps Number of drop packets in this interface is 0 Number of drop-rate notification counts in this interface is 0</pre>

12.5 Monitoring

Clearing

 Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
-------------	---------

Clears statistics of the number of packets dropped during the IPv4 URPF check.	clear ip urpf [interface <i>interface-name</i>]
--	---

Displaying

Description	Command
Displays the IPv4 URPF configuration and statistics.	show ip urpf [interface <i>interface-name</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the URPF events.	debug urpf event
Debugs the URPF timers.	debug urpf timer

13 Configuring GSN

13.1 Overview

Global Security Network (GSN) is a security policy platform consisting of a series of security policies such as access control and network security. The GSN platform includes a device end and a server end. NX Security Policy Management Platform (NX-SMP) server acts as the security policy server for GSN.

In Nodexon General Operation System (NXOS), GSN accepts policies assigned by the SMP server, installs the policies on devices, and determines whether to allow data packets in a certain condition to pass through NX Security Switch. The security policies include binding, isolation, and blocking. Binding is to bind the IP address and MAC address of a user (usually authenticated by the server) on a device. Isolation and blocking are to allow or prohibit transmission of specific data by setting an Access Control List (ACL).

GSN collaborates with the SMP server, 802.1X authentication, and Web authentication.

13.2 Applications

Application	Description
GSN Security Protection for Authenticated Users	After a user passes 802.1X authentication, the SMP server assigns security policies (such as ARP guard and device integrity) to maintain the user's network security.

13.2.1 GSN Security Protection for Authenticated Users

Scenario

After a user passes 802.1X authentication, the SMP server learns the IP-MAC mapping of this user from the Security Account Manager (SAM) server and then assigns security policies to the access device.

Figure 13-1

Remarks	<p>Process description:</p> <ol style="list-style-type: none"> 1. The user passes 802.1X authentication. 2. The SAM server reports user information to the SMP server. 3. After successful authentication, the access device determines whether to adopt the address binding policy for the user based on the configuration. 4. The user exchanges packets with the SMP server in real time, and the access device converts the packet format and forwards the packets. 5. The SMP server assigns security policies to the access device based on information reported by the user. 6. Besides, the SMP server periodically or manually synchronizes policies with the switch. If the SMP server finds that the policies maintained on itself are different from those maintained on the access switch, it deletes all policies on the access device, and then installs all policies maintained on itself onto the access device. 7. During steps 3, 5, and 6, the access device synchronizes and installs the policies based on the policies of GSN.
----------------	--

Deployment

- Enable 802.1X authentication on the access device and deploy the SAM server.
- Deploy the SMP server and add the access device to receive security policies assigned.
- Enable GSN and address binding on the access device.

13.3 Features

Basic Concepts

▾ Nodexon Security Solution

Nodexon security solution is composed of the following four elements:

- NX-SMP platform
- NX Security Agent
- NX Restore System
- NX Security Switch
- **NX-SMP Platform**

Based on the configured policies, the NX-SMP platform determines whether to allow data packets specified in a certain range to pass through NX Security Switch. To install policies is to set policies on a device. To uninstall policies is to remove policies from a device.

▾ NX Security Agent

NX Security Agent is a type of software running on each device that has accessed a corporate network. It collects device information, identifies users' network behaviors, monitors network communication and security status of the devices, and sends collected information to the NX-SMP platform so that the administrator can make security policies accordingly. NX

	security event interval <i>interval</i>	Configures the minimum interval for transmitting security events. The interval value ranges from 1 to 65,535 seconds. The default value is 5 seconds.
Enabling Port-based Address Binding	(Optional) It is used to enable address binding on a port.	
	security address-bind enable	Enables port-based address binding. This policy is disabled by default.

13.4.1 Configuring GSN Basic Functions

Configuration Effect

- Globally enable GSN on devices.
- Enable devices to communicate with the SMP server.

Notes

- You can configure SNMPv1, SNMPv2, or SNMPv3 as the name of the security authentication mechanism for communication with the SMP server.
- To facilitate user configuration, **security v1 community** and **security community** are both used to configure SNMPv1. If SNMPv3 is selected, you must configure SNMPv3 users under the **snmp-server** command. For details about configuration commands, refer to the section *Configuring SNMP*.
- Do not exceed the number of entries supported by GSN.

Configuration Steps

↘ Globally Enabling GSN

- Mandatory.
- Unless otherwise specified, enable GSN on each device that requires the security solution.

↘ Enabling Communication with the SMP Server

- Mandatory.
- Unless otherwise specified, enable this function on each device that requires the security solution to communicate with the SMP server.

↘ Configuring the IP Address of the SMP Server

- Mandatory.
- Unless otherwise specified, configure the IP address of the SMP server on each device that requires the security solution to communicate with the SMP server.

↘ Configuring the Minimum Interval for Transmitting Security Events

- To prevent unauthorized users from frequently sending security events to attack NX Security Switch and the SMP server by faking security events, you can configure the minimum interval for transmitting security events to restrict users from reporting security events.
- If you want to modify the default minimum interval for transmitting the security events, run the related command. The default interval is 5 seconds.

Related Commands

↳ Globally Enabling GSN

Command	security gsn enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

↳ Enabling Communication with the SMP Server

Command	security { [v1 v2] community <i>community</i> v3 user <i>username</i> }
Parameter Description	community <i>community</i> : Specifies the name of the security authentication mechanism for communication with the SMP server. user <i>username</i> : Indicates the name of an SNMPv3 user.
Command Mode	Global configuration mode
Usage Guide	To facilitate user configuration, security v1 community and security community are both used to configure SNMPv1. If SNMPv3 is selected, you must configure SNMPv3 users under the snmp-server command. For details about configuration commands, refer to the section <i>Configuring SNMP</i> .

↳ Configuring the IP Address of the SMP Server

Command	smp-server host <i>ip-address</i>
Parameter Description	<i>ip-address</i> : Specifies the IP address of the SMP server.
Command Mode	Global configuration mode

↳ Configuring the Minimum Interval for Transmitting Security Events

Command	security event interval <i>interval</i>
Parameter Description	interval <i>interval</i> : Specifies the minimum interval for transmitting security events. The value ranges from 1 to 65,535 seconds. The default value is 5 seconds.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuration Example

▾ Enabling GSN and the Communication with the SMP Server

Configuration Steps	<ul style="list-style-type: none"> ● Globally enable GSN on the device. ● Configure the name of the security authentication mechanism for devices to communicate with the SMP server. ● Configure the IP address of the SMP server.
	<pre>Nodexon# configure terminal Nodexon(config)# security gsn enable Nodexon(config)# security vl community test-name Nodexon(config)# smp-server host 192.168.30.9 Nodexon(config)# exit</pre>
Verification	<p>Run the following show commands:</p> <ul style="list-style-type: none"> ● Run the show smp-server command to display the IP address of the SMP server. ● Run the show security event interval command to display the minimum interval for transmitting security events.
	<pre>Nodexon# show smp-server SMP-Server IP:192.168.30.9 Nodexon# show security event interval</pre>

Event sending interval(Seconds):5

Common Errors

- Routes to the SMP server are unavailable.

13.4.2 Enabling Port-based Address Binding

Configuration Effect

- Enable address binding on a port.

Notes

This function takes effect only when GSN is globally enabled and the configured port is an authentication port.

Due to the application features of GSN, you need to disable 802.1X-based IP address authorization before enabling GSN. GSN and 802.1X-based IP address authorization cannot be enabled at the same time. Otherwise, the running of security policies will be affected.

Configuration Steps

▾ Enabling Port-based Address Binding

- To enable address binding based on a port, run the **security address-bind enable** command.

Related Commands

▾ Enabling Port-based Address Binding

Command	security address-bind enable
Defaults	Port-based address binding is disabled by default.
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

▾ Enabling Port-based Address Binding

Configuration Steps	<ul style="list-style-type: none"> ● Enter the interface configuration mode. ● Enable port-based address binding.
	<pre>Nodexon# configure terminal Nodexon(config)# interface gigabitEthernet 0/3 Nodexon(config-if-GigabitEthernet 0/3)# security address-bind enable Nodexon(config)# exit</pre>

13.5 Monitoring

Displaying

Description	Command
Displays the IP address of the SMP server.	show smp-server
Displays the minimum interval for transmitting security events.	show security event interval

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs GSN.	debug gsn { all error event packet server detail }

14 Configuring CPP

14.1 Overview

The CPU Protect Policy (CPP) provides policies for protecting the CPU of a switch.

In network environments, various attack packets spread, which may cause high CPU usages of the switches, affect protocol running and even difficulty in switch management. To this end, switch CPUs must be protected, that is, traffic control and priority-based processing must be performed for various incoming packets to ensure the processing capabilities of the switch CPUs.

CPP can effectively prevent malicious attacks in the network and provide a clean environment for legitimate protocol packets.

CPP is enabled by default. It provides protection during the entire operation of switches.

14.2 Applications

Application	Description
Preventing Malicious Attacks	When various malicious attacks such as ARP attacks intrude in a network, CPP divides attack packets into queues of different priorities so that the attack packets will not affect other packets.
Preventing CPU Processing Bottlenecks	Even when no attacks exist, it would become a bottleneck for CPU to handle excessive normal traffic. CPP can limit the rate of packets being sent to the CPU to ensure normal operation of switches.

14.2.1 Preventing Malicious Attacks

Scenario

Network switches at all levels may be attacked by malicious packets, typically ARP attacks.

As shown in Figure 14-1, switch CPUs process three types of packets: forwarding-plane, control-plane and protocol-plane. Forwarding-plane packets are used for routing, including ARP packets and IP route disconnection packets. Control-plane packets are used to manage services on switches, including Telnet packets and HTTP packets. Protocol-plane packets serve for running protocols, including BPDU packets and OSPF packets.

When an attacker initiates attacks by using ARP packets, the ARP packets will be sent to the CPU for processing. Since the CPU has limited processing capabilities, the ARP packets may force out other packets (which may be discarded) and consume many CPU resources (for processing ARP attack packets). Consequently, the CPU fails to work normally. In the scenario as shown in Figure 14-1, possible consequences include: common users fail to access the network; administrators fail to manage switches; the OSPF link between switch A and the neighbor B is disconnected and route learning fails.

Figure 14-1 Networking Topology of Switch Services and Attacks

Deployment

- By default, CPP classifies ARP packets, Telnet packets, IP route disconnection packets, and OSPF packets into queues of different priorities. In this way, ARP packets will not affect other packets.
- By default, CPP limits the rates of ARP packets and the rates of the priority queue where the ARP packets reside to ensure that the attack packets do not occupy too many CPU resources.
- Packets in the same priority queue with ARP packets may be affected by ARP attack packets. You can divide the packets and the ARP packets into different priority queues by means of configuration.
- When ARP attack packets exist, CPP cannot prevent normal ARP packets from being affected. CPP can only differentiate the packet type but cannot distinguish attack packets from normal packets of the same type. In this case, the Network Foundation Protection Policy (NFPP) function can be used to provide higher-granularity attack prevention.

i For description of NFPP configurations, see the *Configuring NFPP*.

14.2.2 Preventing CPU Processing Bottlenecks

Scenario

Even though no attacks exist, many packets may need to be sent to the CPU for processing at an instant.

For example, the accesses to the core device of a campus network are counted in ten thousands. The traffic of normal ARP packets may reach dozens of thousands packets per second (PPS). If all packets are sent to the CPU for processing, the CPU resources cannot support the processing, which may cause protocol flapping and abnormal CPU running.

Deployment

- By default, the CPP function limits the rates of ARP packets and the rates of the priority queue where the APR packets reside to control the rate of ARP packets sent to the CPU and ensure that the CPU resource consumption is within a specified range and that the CPU can normally process other protocols.
- By default, the CPP function also limits the rates of other packets at the user level, such as Web authentication and 802.1X authentication packets.

14.3 Features

Basic Concepts

↳ QoS, DiffServ

Quality of Service (QoS) is a network security mechanism, a technology used to solve the problems of network delay and congestion.

DiffServ refers to the differentiated service model, which is a typical model implemented by QoS for classifying service streams to provide differentiated services.

↳ Bandwidth, Rate

Bandwidth refers to the maximum allowable data rate, which refers to the rate threshold in this document. Packets whose rates exceed the threshold will be discarded.

The rate indicates an actual data rate. When the rate of packets exceeds the bandwidth, packets out of the limit will be discarded. The rate must be equal to or smaller than the bandwidth.

The bandwidth and rate units in this document are packets per second (pps).

↳ L2, L3, L4

The structure of packets is hierarchical based on the TCP/IP model.

L2 refers to layer-2 headers, namely, the Ethernet encapsulation part; L3 refers to layer-3 headers, namely, the IP encapsulation part; L4 refers to layer-4 headers, usually, the TCP/UDP encapsulation part.

↳ Priority Queue, SP

Packets are cached inside a switch and packets in the output direction are cached in queues. Priority queues are mapped to Strict Priorities (SPs). Queues are not equal but have different priorities.

The SP is a kind of QoS scheduling algorithm. When a higher priority queue has packets, the packets in this queue are scheduled first. Scheduling refers to selecting packets from queues for output and refers to selecting and sending the packets to the CPU in this document.

↳ CPU interface

Before sending packets to the CPU, a switch will cache the packets. The process of sending packets to the CPU is similar to the process of packet output. The CPU interface is a virtual interface. When packets are sent to the CPU, the packets will be output from this virtual interface. The priority queue and SP mentioned above are based on the CPU interface.

Overview

CPP protects the CPU by using the standard QoS DiffServ model.

Figure 14-2 CPP Implementation Model

Feature	Description
Classifier	Classifies packet types and provides assurance for the subsequent implementation of QoS policies.
Meter	Limits rates based on packet types and controls the bandwidth for a specific packet type.
Queue	Queue packets to be sent to the CPU and select different queues based on packet types.
Scheduler	Selects and schedules queues to be sent to the CPU.
Shaper	Performs rate limit and bandwidth control on priority queues and the CPU interface.

14.3.1 Classifier

Working Principle

The Classifier classifies all packets to be sent to the CPU based on the L2, L3 and L4 information of the packets. Classifying packets is the basis for implementing QoS policies. In subsequent actions, different policies are implemented based on the classification to provide differentiated services. A switch provides fixed classification. The management function classifies packet types based on the protocols supported by the switch, for example, STP BPDU packets and ICMP packets. Packet types cannot be customized.

14.3.2 Meter

Working Principle

The Meter limits the rates of different packets based on the preset rate thresholds. You can set different rate thresholds for different packet types. When the rate of a packet type exceeds the corresponding threshold, the packets out of the limit will be discarded.

By using the Meter, you can control the rate of a packet type sent to the CPU within a threshold to prevent specific attack packets from exerting large impacts on the CPU resources. This is the level-1 protection of the CPP.

Related Configuration

- By default, each packet type corresponds to a rate threshold (bandwidth) and Meter policies are implemented based on the rate threshold.
- In application, you can run the `cpu-protect type packet-type bandwidth bandwidth-value` command to set Meter policies for specified packet types.

14.3.3 Queue

Working Principle

Queues are used to classify packets at level 2. You can select the same queue for different packet types; meanwhile, queues cache packets inside switches and provide services for the Scheduler and Shaper.

CPP queues are SP queues. The SPs of the packets are determined based on the time when they are added to a queue. Packets with a larger queue number have a higher priority.

Related Configuration

- By default, each packet type is mapped to an SP queue.
- In application, you can run the **cpu-protect type** *packet-type* **traffic-class** *traffic-class-num* command to select SP queues for specific packet types.

14.3.4 Scheduler

Working Principle

The Scheduler schedules packets based on SPs of queues. That is, packets in a queue with a higher priority are scheduled first.

Before being scheduled, packets to be sent to the CPU are cached in queues. When being scheduled, the packets are sent to the CPU for processing.

 Only the SP scheduling policy is supported and cannot be modified.

14.3.5 Shaper

Working Principle

The Shaper is used to shape packets to be sent to the CPU, that is, when the actual rate of packets is greater than the shaping threshold, the packets must stay in the queue and cannot be scheduled. When packet rates fluctuate, the Shaper ensures that the rates of packets sent to the CPU are smooth (no more than the shaping threshold).

When the Shaper is available, packets in a queue with a lower priority may be scheduled before all packets in a queue with a higher priority are scheduled. If the rate of packets in a queue with certain priority exceeds the shaping threshold, scheduling of the packets in this queue may be stopped temporarily. Therefore, the Shaper can prevent packets in queues with lower priorities from starvation (which means that only packets in queues with higher priorities are scheduled and packets in queues with higher priorities are not scheduled).

Since the Shaper limits the scheduling rates of packets, it actually plays the rate limit function. The Shaper provides level-2 rate limit for priority queues and all packets sent to the CPU (CPU interface). The Shaper and Meter functions provide 3-level rate limit together and provide level-3 protection for the CPU.

Figure 14-3 Level Rate Limit of the CPP

Related Configuration

Configuring the Shaper for priority queues

- By default, each priority queue determines a shaping threshold (bandwidth).
- In application, you can run the **cpu-protect traffic-class traffic-class-num bandwidth bandwidth_value** command to perform Shaper configuration for a specific priority queue.

Configuring the Shaper for the CPU Interface

- By default, the CPU interface determines a shaping threshold (bandwidth).
- Run the **cpu-protect cpu bandwidth bandwidth_value** command to perform Shaper configuration for the CPU interface.

14.4 Configuration

Configuration	Description and Command	
Configuring CPP	 (Optional and configured by default) It is used to adjust the configuration parameters of CPP.	
	cpu-protect type packet-type bandwidth	Configures the Meter for a packet type.
	cpu-protect type packet-type traffic-class	Configures the priority queue for a packet type.
	cpu-protect traffic-class traffic-class-num bandwidth	Configures the Shaper for a priority queue.
	cpu-protect cpu bandwidth	Configures the Shaper for the CPU interface.

14.4.1 Configuring CPP

Configuration Effect

- By configuring the Meter function, you can set the bandwidth and rate limit for a packet type. Packets out of the limit will be directly discarded.
- By configuring the Queue function, you can select a priority queue for a packet type. Packets in a queue with a higher priority will be scheduled first.
- By configuring the Shaper function, you can set the bandwidth and rate limit for a CPU interface and a priority queue. Packets out of the limit will be directly discarded.

Notes

- Pay special attention when the bandwidth of a packet type is set to a smaller value, which may affect the normal traffic of the same type. To provide per-user CPP, combine the NFPP function.
- When the Meter and Shaper functions are combined, 3-level protection will be provided. Any level protection fights alone may bring negative effects. For example, if you want to increase the Meter of a packet type, you also need to adjust the Shaper of the corresponding priority queue. Otherwise, the packets of this type may affect other types of packets in the same priority queue.

Configuration Steps

▾ Configuring the Meter for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: when packets of a type are not attackers but are discarded, you need to increase the Meter of this packet type. If attacks of a packet type cause abnormal CPU running, you need to decrease the Meter of this packet type.
- This configuration is available on all switches in a network environment.

▾ Configuring the priority queue for a packet type

- You can use or modify the default value but cannot disable it.
- You need to modify the configuration in the following cases: When attacks of a packet type cause abnormality of other packets in the same queue, you can put the packet type in an unused queue. If a packet type cannot be discarded but the packet type is in the same queue with other packet types in use, you can put this packet type in a queue with a higher priority.
- This configuration is available on all switches in a network environment.

▾ Configuring the Shaper for a priority queue

- You can use or modify the default value and cannot disable it.
- You need to modify the configuration in the following cases: If the Meter value of a packet type is greater which causes that other packets in the corresponding priority queue do not have sufficient bandwidth, you need to increase the

Shaper for this priority queue. If attack packets are put in a priority queue and no other packets are in use, you need to increase the Shaper of this priority queue.

- This configuration is available on all switches in a network environment.

↘ **Configuring the Shaper for the CPU interface**

- You can use or modify the default value and cannot disable it.
- You are not advised to change the Shaper of the CPU interface.
- This configuration is available on all switches in a network environment.

Verification

- Modify the configurations when the system runs abnormally, and view the system running after the modification to check whether the configurations take effect.
- Check whether the configurations take effect by viewing corresponding configurations and statistic values. For details, see the following commands.

Related Commands

↘ **Configuring the Meter for a packet type**

Command	cpu-protect type <i>packet-type</i> bandwidth <i>bandwidth_value</i>
Parameter	<i>packet-type</i> : Specifies a packet type. Packet types are defined.
Description	<i>bandwidth_value</i> : Sets the bandwidth, in the unit of packets per second (pps).
Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Configuring the priority queue for a packet type**

Command	cpu-protect type <i>packet-type</i> traffic-class <i>traffic-class-num</i>
Parameter	<i>packet-type</i> : Specifies a packet type. Packet types are defined.
Description	<i>traffic-class-num</i> : Specifies a priority queue.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Configuring the Shaper for a priority queue**

Command	cpu-protect traffic-class <i>traffic-class-num</i> bandwidth <i>bandwidth_value</i>
Parameter	<i>traffic-class-num</i> : Specifies a priority queue.
Description	<i>bandwidth_value</i> : Sets the bandwidth, in the unit of pps.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ **Configuring the Shaper for a CPU interface**

Command	cpu-protect cpu bandwidth <i>bandwidth_value</i>
Parameter	<i>bandwidth_value</i> : Sets the bandwidth, in the unit of pps.
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

➤ **Preventing packet attacks and network flapping by using CPP**

Scenario	<ul style="list-style-type: none"> ● ARP, IP, OSPF, dot1x, VRRP, Telnet and ICMP streams are available in the system. In the current configurations, ARP and 802.1X are in priority queue 2; IP, ICMP and Telnet streams are in priority queue 4; OSPF streams are in priority queue 3; VRRP streams are in priority queue 6. The Meter for each packet type is 10,000 pps; the shaper for each priority queue is 20,000 pps; the Shaper for the CPU interface is 100,000 pps. ● ARP attacks and IP scanning attacks exist in the system, which causes abnormal running of the system, authentication failure, Ping failure, management failure, and OSPF flapping.
Configuration Steps	<ul style="list-style-type: none"> ● Put ARP attack packets in priority queue 1 and limit the bandwidth for ARP packets or the corresponding priority queue. ● Put OSPF packets in priority queue 5. ● Put IP Ping failure attack packets in priority queue 3 and limit the bandwidth for IP packets or the corresponding priority queue.
	<pre>Nodexon# configure terminal Nodexon(config)# cpu-protect type arp traffic-class 1 Nodexon(config)# cpu-protect type arp bandwidth 5000 Nodexon(config)# cpu-protect type ospf traffic-class 5 Nodexon(config)# cpu-protect type v4uc-route traffic-class 3 Nodexon(config)# cpu-protect type traffic-class 3 bandwidth 5000 Nodexon(config)# end</pre>
Verification	<p>Run the show cpu-protect command to view the configuration and statistics.</p> <pre>Nodexon#show cpu-protect%cpu port bandwidth: 100000 (pps) Traffic-class Bandwidth(pps) Rate(pps) Drop(pps) ----- 0 6000 0 0 1 6000 0 0 2 6000 0 0</pre>

14.5 Monitoring

Clearing

Description	Command
Clears the CPP statistics.	clear cpu-protect counters [device <i>device_num</i>]
Clears the CPP statistics on the master device.	clear cpu-protect counters mboard

Displaying

Description	Command
Displays the configuration and statistics of a packet type.	show cpu-protect type <i>packet-type</i> [device <i>device_num</i>]
Displays the configuration and statistics of a priority queue.	show cpu-protect traffic-class <i>traffic-class-num</i> [device <i>device_num</i>]
Displays the configuration on a CPU interface.	show cpu-protect cpu
Displays all configurations and statistics on the master device.	show cpu-protect { mboard summary }
Displays all configurations and statistics of CPP.	show cpu-protect [device <i>device_num</i>]

Debugging

N/A

- i** The preceding monitoring commands are available on devices in either the standalone mode or the VSU mode.
- i** If the **device** value is not specified, the **clear** command is used to clear the statistics of all nodes in the system and the **show** command is used to display the configurations on the master device.
- i** In the VSU mode, the parameter **device** indicates a device. If the **device** value is not specified, it indicates the master device or the master device.

15 Configuring DHCP Snooping

15.1 Overview

DHCP Snooping: DHCP Snooping snoops DHCP interactive packets between clients and servers to record and monitor users' IP addresses and filter out illegal DHCP packets, including client request packets and server response packets. The legal user database generated from DHCP Snooping records may serve security applications like IP Source Guard.

Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions

15.2 Applications

Application	Description
Guarding against DHCP service spoofing	In a network with multiple DHCP servers, DHCP clients are allowed to obtain network configurations only from legal DHCP servers.
Guarding against DHCP packet flooding	Malicious network users may frequently send DHCP request packets.
Guarding against forged DHCP packets	Malicious network users may send forged DHCP request packets, for example, DHCP-RELEASE packets.
Guarding against IP/MAC spoofing	Malicious network users may send forged IP packets, for example, tampered source address fields of packets.
Preventing Lease of IP Addresses	Network users may lease IP addresses rather than obtaining them from a DHCP server.
Detecting ARP attack	Malicious users forge ARP response packets to intercept packets during normal users' communication.

15.2.1 Guarding Against DHCP Service Spoofing

Scenario

Multiple DHCP servers may exist in a network. It is essential to ensure that user PCs obtain network configurations only from the DHCP servers within a controlled area.

Take the following figure as an example. The DHCP client can only communicate with trusted DHCP servers.

- Request packets from the DHCP client can be transmitted only to trusted DHCP servers.
- Only the response packets from trusted DHCP servers can be transmitted to the client.

Figure 15-1

Remarks:	<p>S is an access device.</p> <p>A is a user PC.</p> <p>B is a DHCP server within the controlled area.</p> <p>C is a DHCP server out of the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP packet monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.

15.2.2 Guarding Against DHCP Packet Flooding

Scenario

Potential malicious DHCP clients in a network may send high-rate DHCP packets. As a result, legitimate users cannot obtain IP addresses, and access devices are highly loaded or even break down. It is necessary to take actions to ensure network stability.

With the DHCP Snooping rate limit function for DHCP packets, a DHCP client can only send DHCP request packets at a rate below the limit.

- The request packets from a DHCP client are sent at a rate below the limit.
- Packets sent at rates beyond the limit will be discarded.
- Enable DHCP Snooping correlation with ARP, and delete the non-existing entries.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Limit the rates of DHCP packets from the untrusted ports.

- Enable DHCP Snooping correlation with ARP, and detect whether the user is online.

15.2.3 Guarding Against Forged DHCP Packets

Scenario

Potential malicious clients in a network may forge DHCP request packets, consuming applicable IP addresses from the servers and probably preempting legal users' IP addresses. Therefore, it is necessary to filter out illegal DHCP packets.

For example, as shown in the figure below, the DHCP request packets sent from DHCP clients will be checked.

- The source MAC address fields of the request packets from DHCP clients must match the **chaddr** fields of DHCP packets.
- The Release packets and Decline packets from clients must match the entries in the DHCP Snooping binding database.

Figure 15-2

Remarks:	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a DHCP server within the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set the port on S connecting to B as trusted to transfer response packets.
- Set the rest of ports on S as untrusted to filter response packets.
- Enable DHCP Snooping Source MAC Verification on untrusted ports of S to filter out illegal packets.

15.2.4 Guarding Against IP/MAC Spoofing

Scenario

Check IP packets from untrusted ports to filter out forged IP packets based on IP or IP-MAC fields.

For example, in the following figure, the IP packets sent by DHCP clients are validated.

- The source IP address fields of IP packets must match the IP addresses assigned by DHCP.
- The source MAC address fields of layer-2 packets must match the **chaddr** fields in DHCP request packets from clients.

Figure 15-3

Remarks:	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a DHCP server within the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as DHCP Snooping untrusted.
- Enable IP Source Guard on S to filter IP packets.
- Enable IP Source Guard in IP-MAC based mode to check the source MAC and IP address fields of IP packets.

15.2.5 Preventing Lease of IP Addresses

Scenario

Validate the source addresses of IP packets from untrusted ports compared with DHCP-assigned addresses.

If the source addresses, connected ports, and layer-2 source MAC addresses of ports in IP packets do not match the assignments of the DHCP server, such packets will be discarded.

The networking topology scenario is the same as that shown in the previous figure.

Deployment

- The same as that in the section "Guarding Against IP/MAC Spoofing".

15.2.6 Detecting ARP Attacks

Scenario

Check the ARP packets from untrusted ports and filter out the ARP packets unmatched with the assignments of the DHCP server.

For example, in the following figure, the ARP packets sent from DHCP clients will be checked.

- The ports receiving ARP packets, the layer-2 MAC addresses, and the source MAC addresses of ARP packets senders shall be consistent with the DHCP Snooping histories.

Figure 15-4

Remarks:	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a DHCP server within the controlled area.</p>
-----------------	--

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on the S as untrusted.
- Enable IP Source Guard and ARP Check on all the untrusted ports on S to realize ARP packet filtering.

⚠ All the above security control functions are only effective to DHCP Snooping untrusted ports.

15.3 Features

Basic Concepts

↳ DHCP Request Packets

Request packets are sent from a DHCP client to a DHCP server, including DHCP-DISCOVER packets, DHCP-REQUEST packets, DHCP-DECLINE packets, DHCP-RELEASE packets and DHCP-INFORM packets.

↳ DHCP Response Packets

Response packets are sent from a DHCP server to a DHCP client, including DHCP-OFFER packets, DHCP-ACK packets and DHCP-NAK packets.

↳ DHCP Snooping Trusted Ports

IP address request interaction is complete via broadcast. Therefore, illegal DHCP services will influence normal clients' acquisition of IP addresses and lead to service spoofing and stealing. To prevent illegal DHCP services, DHCP Snooping ports are divided into two types: trusted ports and untrusted ports. The access devices only transmit DHCP response packets received on trusted ports, while such packets from untrusted ports are discarded. In this way, we may configure the ports connected to a legal DHCP Server as trusted and the other ports as untrusted to shield illegal DHCP Servers.

On switches, all switching ports or layer-2 aggregate ports are defaulted as untrusted, while trusted ports can be specified.

↳ DHCP Snooping Packet Suppression

To shield all the DHCP packets on a specific client, we can enable DHCP Snooping packet suppression on its untrusted ports.

↳ VLAN-based DHCP Snooping

DHCP Snooping can work on a VLAN basis. By default, when DHCP Snooping is enabled, it is effective to all the VLANs of the current client. Specify VLANs help control the effective range of DHCP Snooping flexibly.

↳ DHCP Snooping Binding Database

In a DHCP network, clients may set static IP addresses randomly. This increases not only the difficulty of network maintenance but also the possibility that legal clients with IP addresses assigned by the DHCP server may fail to use the network normally due to address conflict. Through snooping packets between clients and servers, DHCP Snooping summarizes the user entries including IP addresses, MAC address, VLAN ID (VID), ports and lease time to build the DHCP Snooping binding database. Combined with ARP detection and ARP check, DHCP Snooping controls the reliable assignment of IP addresses for legal clients.

↳ DHCP Snooping Rate Limit

DHCP Snooping rate limit function can be configured through the rate limit command of Network Foundation Protection Policy (NFPP). For NFPP configuration, see the *Configuring NFPP*.

↳ DHCP Option82

DHCP Option82, an option for DHCP packets, is also called DHCP Relay Agent Information Option. As the option number is 82, it is known as Option82. Option82 is developed to enhance the security of DHCP servers and improve the strategies of IP address assignment. The option is often configured for the DHCP relay services of a network access device like DHCP Relay and DHCP Snooping. This option is transparent to DHCP clients, and DHCP relay components realize the addition and deduction of the option.

↘ Illegal DHCP Packets

Through DHCP Snooping, validation is performed on the DHCP packets passing through a client. Illegal DHCP packets are discarded, user information is recorded into the DHCP Snooping binding database for further applications (for example, ARP detection). The following types of packets are considered illegal DHCP packets.

- The DHCP response packets received on untrusted ports, including DHCP-ACK, DHCP-NACK and DHCP-OFFER packets
- The DHCP request packets carrying gateway information **giaddr**, which are received on untrusted ports
- When MAC verification is enabled, packets with source MAC addresses different with the value of the **chaddr** field in DHCP packets
- DHCP-RELEASE packets with the entry in the DHCP Snooping binding database Snooping while with untrusted ports inconsistent with settings in this binding database
- DHCP packets in wrong formats, or incomplete

Overview

Feature	Description
Filtering DHCP packets	Perform legality check on DHCP packets and discard illegal packets (see the previous section for the introduction of illegal packets). Transfer requests packets received on trusted ports only.
Building the DHCP Snooping binding database	Snoop the interaction between DHCP clients and the server, and generate the DHCP Snooping binding database to provide basis for other filtering modules.

15.3.1 Filtering DHCP Packets

Perform validation on DHCP packets from untrusted ports. Filter out the illegal packets as introduced in the previous section "Basic Concepts".

Working Principle

During snooping, check the receiving ports and the packet fields of packets to realize packet filtering, and modify the destination ports of packets to realize control of transmit range of the packets.

↘ Checking Ports

In receipt of DHCP packets, a client first judges whether the packet receiving ports are DHCP Snooping trusted ports. If yes, legality check and binding entry addition are skipped, and packets are transferred directly. For not, both the check and addition are needed.

↘ Checking Packet Encapsulation and Length

A client checks whether packets are UDP packets and whether the destination port is 67 or 68. Check whether the packet length match the length field defined in protocols.

↘ Checking Packet Fields and Types

According to the types of illegal packet introduced in the section "Basic Concepts", check the fields **giaddr** and **chaddr** in packets and then check whether the restrictive conditions for the type of the packet are met.

Related Configuration

↘ Enabling Global DHCP Snooping

By default, DHCP Snooping is disabled.

It can be enabled on a device using the **ip dhcp snooping** command.

Global DHCP Snooping must be enabled before VLAN-based DHCP Snooping is applied.

↘ Configuring VLAN-based DHCP Snooping

By default, when global DHCP Snooping is effective, DHCP Snooping is effective to all VLANs.

Use the [**no**] **ip dhcp snooping vlan** command to enable DHCP Snooping on specified VLANs or delete VLANs from the specified VLANs. The value range of the command parameter is the actual range of VLAN numbers.

↘ Configuring DHCP Snooping Source MAC Verification

By default, the layer-2 MAC addresses of packets and the **chaddr** fields of DHCP packets are not verified.

When the **ip dhcp snooping verify mac-address** command is used, the source MAC addresses and the **chaddr** fields of the DHCP request packets sent from untrusted ports are verified. The DHCP request packets with different MAC addresses will be discarded.

15.3.2 Building the Binding Database

DHCP Snooping detects the interactive packets between DHCP clients and the DHCP server, and generate entries of the DHCP Snooping binding database according to the information of legal DHCP packets. All these legal entries are provided to other security modules of a client as the basis of filtering packets from network.

Working Principle

During snooping, the binding database is updated timely based on the types of DHCP packets.

↘ Generating Binding Entries

When a DHCP-ACK packet on a trusted port is snooped, the client's IP address, MAC address, and lease time field are extracted together with the port ID (a wired interface index) and VLAN ID. Then, a binding entry of it is generated.

↘ Deleting Binding Entries

When the recorded lease time of a binding entry is due, it will be deleted if a legal DHCP-RELEASE/DHCP-DECLINE packet sent by the client or a DHCP-NCK packet received on a trusted port is snooped, or the **clear** command is used.

Related Configuration

No configuration is needed except enabling DHCP Snooping.

15.4 Configuration

Configuration	Description and Command	
Configuring basic functions of DHCP Snooping	 (Mandatory) It is used to enable DHCP Snooping.	
	ip dhcp snooping	Enables DHCP Snooping.
	ip dhcp snooping suppression	Enables DHCP Snooping packet suppression.
	ip dhcp snooping vlan	Enables VLAN-based DHCP Snooping.
	ip dhcp snooping verify mac-address	Configures DHCP Snooping source MAC verification.
	ip dhcp snooping database write-delay	Writes the DHCP Snooping binding database to Flash periodically.
	ip dhcp snooping database write-to-flash	Writes the DHCP Snooping binding database to Flash manually.
	renew ip dhcp snooping database	Imports Flash storage to the DHCP Snooping Binding database.
	ip dhcp snooping trust	Configures DHCP Snooping trusted ports.
	ip dhcp snooping bootp	Enables BOOTP support.
	ip dhcp snooping check-giaddr	Enables DHCP Snooping to support the function of processing Relay requests.
ip dhcp snooping loose-forward	Enables loose forwarding.	
Configuring Option82	 (Optional) It is used to optimize the address assignment by DHCP servers.	
	ip dhcp snooping information option	Adds Option82 functions to DHCP request packets.
	ip dhcp snooping information option format remote-id	Configures the sub-option remote-id of Option82 as a user-defined character string.
	ip dhcp snooping vlan information option format-type circuit-id string	Configures the sub-option circuit-id of Option82 as a user-defined character string.
ip dhcp snooping information option strategy	Configures the strategy of Option82.	

15.4.1 Configuring Basic Features

Configuration Effect

- Enable DHCP Snooping.
- Generate the DHCP Snooping binding database.
- Control the transmit range of DHCP packets.
- Filter out illegal DHCP packets.

Notes

- The ports on clients connecting a trusted DHCP server must be configured as trusted.
- DHCP Snooping is effective on the wired switching ports, layer-2 aggregate ports, and layer-2 encapsulation sub-interfaces.
- DHCP Snooping and DHCP Relay are mutually exclusive in VRF scenarios.

Configuration Steps

▾ Enabling Global DHCP Snooping

- Mandatory.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Enabling or Disabling VLAN-based DHCP Snooping

- DHCP Snooping can be disabled if not necessary for some VLANs.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Configuring DHCP Snooping Trusted Ports

- Mandatory.
- Configure the ports connecting a trusted DHCP server as trusted.

▾ Enabling DHCP Snooping Source MAC Validation

- This configuration is required if the **chaddr** fields of DHCP request packets match the layer-2 source MAC addresses of data packets.
- Unless otherwise noted, the feature should be enabled on all the untrusted ports of access devices.

▾ Writing the DHCP Snooping Binding Database to Flash Periodically

- Enable this feature to timely save the DHCP Snooping binding database information in case that client reboot.
- Unless otherwise noted, the feature should be configured on access devices.

▾ Enabling BOOTP Support

- Optional

- Unless otherwise noted, the feature should be configured on access devices.

↘ Enabling DHCP Snooping to Process Relay Requests

- Optional.
- Unless otherwise noted, the feature should be enabled on access devices.

↘ Enabling Loose Forwarding

- Optional.
- Unless otherwise noted, the feature is disabled.

Verification

Configure a client to obtain network configurations through the DHCP protocol.

- Check whether the DHCP Snooping Binding database is generated with entries on the client.

Related Commands

↘ Enabling or Disabling DHCP Snooping

Command	<code>[no] ip dhcp snooping</code>
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After global DHCP Snooping is enabled, you can check DHCP Snooping using the show ip dhcp snooping command.

↘ Configuring VLAN-based DHCP Snooping

Command	<code>[no] ip dhcp snooping vlan { <i>vlan-rng</i> { <i>vlan-min</i> [<i>vlan-max</i>] } }</code>
Parameter Description	<i>vlan-rng</i> : Indicates the range of VLANs <i>vlan-min</i> : The minimum VLAN ID <i>vlan-max</i> : The maximum VLAN ID
Command Mode	Global configuration mode
Usage Guide	Use this command to enable or disable DHCP Snooping on specified VLANs. This feature is available only after global DHCP Snooping is enabled.

↘ Configuring DHCP Snooping Packet Suppression

Command	<code>[no] ip dhcp snooping suppression</code>
Parameter Description	N/A
Command	Interface configuration mode

Mode	
Usage Guide	Use this command to reject all DHCP request packets at the port, that is, to forbid all users under the port to apply for addresses via DHCP.

✚ Configuring DHCP Snooping Source MAC Verification

Command	[no] ip dhcp snooping verify mac-address
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Through the source MAC address verification, the MAC addresses in link headers and the CLIENT MAC fields in the request packets sent by a DHCP CLIENT are checked for consistence. When the source MAC address verification fails, packets will be discarded.

✚ Writing DHCP Snooping Database to Flash Periodically

Command	[no] ip dhcp snooping database write-delay [time]
Parameter Description	<i>time</i> : Indicates the interval between two times of writing the DHCP Snooping database to the Flash.
Command Mode	Global configuration mode
Usage Guide	Use this command to write the DHCP Snooping database to FLASH document. This can avoid binding information loss which requires re-obtaining IP addresses to resume communication after the device restarts.

✚ Writing the DHCP Snooping Database to Flash Manually

Command	ip dhcp snooping database write-to-flash
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to write the dynamic user information in the DHCP Snooping database in FLASH documents in real time. If a device is upgraded from a non-QinQ version to a QinQ version (or vice versa), binding entries cannot be restored from FLASH documents because of version differences between FLASH documents.

✚ Importing Backup File Storage to the DHCP Snooping Binding Database

Command	renew ip dhcp snooping database
Parameter Description	N/A
Command	Privileged configuration mode

Mode	
Usage Guide	Use this command to import the information from backup file to the DHCP Snooping binding database.

▾ Configuring DHCP Snooping Trusted Ports

Command	[no] ip dhcp snooping trust
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure a port connected to a legal DHCP server as a trusted port. The DHCP response packets received by trusted ports are transferred, while those received by untrusted ports are discarded.

▾ Enabling or Disabling BOOTP Support

Command	[no] ip dhcp snooping bootp
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to support the BOOTP protocol.

▾ Enabling DHCP Snooping to Process Relay Requests

Command	[no] ip dhcp snooping check-giaddr
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the feature is enabled, services using DHCP Snooping binding entries generated based on Relay requests, such as IP Source Guard/802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet. After the feature is enabled, the ip dhcp snooping verify mac-address command cannot be used. Otherwise, DHCP Relay requests will be discarded and as a result, users fail to obtain addresses.

▾ Enabling DHCP Snooping Loose Forwarding

Command	ip dhcp snooping loose-forward
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this feature is enabled, when the capacity of DHCP Snooping binding entries is reached, DHCP

packets of new users are forwarded and obtain addresses, but DHCP Snooping does not record binding entries of new users.

Configuration Example

DHCP Client Obtaining IP addresses Dynamically from a Legal DHCP Server

<p>Scenario Figure 15-5</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable DHCP Snooping on an access device (Switch B in this case). ● Configure the uplink port (port Gi 0/1 in this case) as a trusted port.
<p>B</p>	<pre>B#configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)#ip dhcp snooping B(config)#interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ip dhcp snooping trust B(config-if-GigabitEthernet 0/1)#end</pre>
<p>Verification</p>	<p>Check the configuration on Switch B.</p> <ul style="list-style-type: none"> ● Check whether DHCP Snooping is enabled, and whether the configured DHCP Snooping trusted port is uplink. ● Check the DHCP Snooping configuration on Switch B, and especially whether the trusted port is correct.
<p>B</p>	<pre>B#show running-config ! ip dhcp snooping ! interface GigabitEthernet 0/1 B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds</pre>

```

DHCP Snooping option 82 status           :  DISABLE
DHCP Snooping Support BOOTP bind status  :  DISABLE
Interface           Trusted           Rate limit (pps)
-----
GigabitEthernet 0/1           YES           unlimited
B#show ip dhcp snooping binding
Total number of bindings: 1
-----
MacAddress           IPAddress           Lease(sec)           Type           VLAN           Interface
-----
0013.2049.9014           172.16.1.2           86207           DHCP-Snooping 1           GigabitEthernet 0/11
    
```

Common Errors

- The uplink port is not configured as a DHCP trusted port.
- Another access security option is already configured for the uplink port, so that a DHCP trusted port cannot be configured.

15.4.2 Configuring Option82

Configuration Effect

- Enable a DHCP server to obtain more information and assign addresses better.
- The Option82 function is client-oblivious.

Notes

- The Option82 functions for DHCP Snooping and DHCP Relay are mutually exclusive.

Configuration Steps

- To realize optimization of address allocation, implement the configuration.
- Unless otherwise noted, enable this function on access devices with DHCP Snooping enabled.

Verification

Check whether the DHCP Snooping configuration options are configured successfully.

Related Commands

Adding Option82 to DHCP Request Packets

Command	[no] ip dhcp snooping information option [standard-format dot1x-format]
Parameter	standard-format : Indicates a standard format of the Option82 options
Description	dot1x-format : Indicates a dot1x format of the Option82 options
Command Mode	Global configuration mode

Usage Guide	Use this command to add Option82 to DHCP request packets so that a DHCP server assigns addresses according to such information. When dot1x-format is used, if DHCP Relay is configured on the local device and the uplink port connected to the DHCP Server is an SVI port, DHCP Snooping needs to be disabled in the VLAN to which the SVI port belongs.
--------------------	--

↘ Configuring Sub-option remote-id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping information option format remote-id { string <i>ASCII-string</i> hostname }
Parameter Description	string <i>ASCII-string</i> : Indicates the content of the extensible format, the Option82 option remote-id , is a user-defined character string hostname : Indicates the content of the extensible format, the Option82 option remote-id , is a host name.
Configuration mode	Global configuration mode
Usage Guide	Use this command to configure the sub-option remote-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

↘ Configuring Sub-Option circuit -id of Option82 as User-defined Character String

Command	[no] ip dhcp snooping vlan <i>vlan-id</i> information option format-type circuit-id string <i>ascii-string</i>
Parameter Description	vlan-id : Indicates the VLAN where a DHCP request packet is ascii-string : Indicates the user-defined string
Configuration mode	Interface configuration mode
Usage Guide	Use this command to configure the sub-option circuit-id of the Option82 as user-defined content, which is added to DHCP request packets. A DHCP server assigns addresses according to Option82 information.

↘ Configuring the Strategy of Option82

Command	ip dhcp snooping information option strategy {keep drop replace}
Parameter Description	keep : Indicates reception of request packets with Option82. Option82 is kept and the packets are forwarded. drop : Indicates reception of request packets with Option82. The packets are dropped. replace : Indicates reception of request packets with Option82. Option82 of the packets are replaced with Option82 configured latest. The packets are forwarded.
Configuration mode	Global configuration mode
Usage Guide	This command only works for request packets with Option82. If the strategy is keep or drop, there is no need to configure sub-option circuit-id of the Option82. If the strategy is replace, sub-option circuit-id of the Option82 needs configuring. In terms of request packets without Option82, configured sub-option circuit-id of the Option82 is added.

Configuration Example

↘ Configuring Option82 to DHCP Request Packets

Description	Command
Debugs DHCP Snooping events.	debug snooping ipv4 event
Disables debugging DHCP Snooping events.	no debug snooping ipv4 event
Debugs DHCP Snooping packets.	debug snooping ipv4 packet
Disables debugging DHCP Snooping packets.	no debug snooping ipv4 packet
Enables debugging MAC-based DHCP Snooping.	debug snooping ipv4 mac-address <i>H.H.H</i>
Disables debugging MAC-based DHCP Snooping.	no debug snooping ipv4 mac-address <i>H.H.H</i>
Enables debugging all DHCP Snooping	debug snooping ipv4 all
Disables debugging all DHCP Snooping	no debug snooping ipv4 all

16 Configuring DHCPv6 Snooping

16.1 Overview

DHCPv6 Snooping: Dynamic Host Configuration Protocol version 6 (DHCPv6) snooping enables recording and monitoring of IPv6 address usage by snooping DHCPv6 packets exchanged between the client and the server, and filters illegal DHCPv6 packets, including request packets from the client and response packets from the server. The user data entries generated by DHCPv6 snooping recording can serve security applications such as IPv6 Source Guard.

Protocols and Standards

- RFC3315 Dynamic Host Configuration Protocol For IPv6
- RFC5007 DHCPv6 Leasequery
- RFC5460 DHCPv6 Bulk Leasequery

16.2 Applications

Application	Description
Prevention of DHCPv6 Spoofing	There is more than one DHCPv6 server on the network, and DHCPv6 clients can obtain network configuration parameters only from legal DHCPv6 servers.
Prevention of Forged DHCPv6 Packet Attacks	Malicious users on the network frequently send DHCPv6 request packets.
Prevention of Forged DHCPv6 Packet Attacks	Malicious users on the network send forged DHCPv6 request packets such as DHCPv6 release packets.
Prevention of IPv6/MAC Spoofing	Malicious users on the network send forged IPv6 request packets that temper the source address fields.
Prevention of Unauthorized IPv6 Configuration	Users do not obtain IPv6 addresses from the DHCPv6 server as required and configure IPv6 addresses without authorization.

16.2.1 Prevention of DHCPv6 Spoofing

Scenario

There may exist more than one DHCPv6 server on the network, and it is necessary to ensure that user PCs obtain network configuration parameters only from the controlled DHCPv6 servers.

As shown in the following figure, the DHCPv6 client only communicates with trusted DHCPv6 servers.

- The request packets from the DHCPv6 client are transmitted only to a trusted DHCPv6 server.
- Only the response packets from the trusted DHCPv6 server can be transmitted to the client.

Figure 16-1

Remarks	<p>S is an access device.</p> <p>A is a user PC.</p> <p>B is a controlled DHCPv6 server.</p> <p>C is an uncontrolled DHCPv6 server.</p>
----------------	---

Deployment

- Enable DHCPv6 snooping on the access device S for DHCPv6 packet monitoring.
- Set the port connecting the access device S to the DHCPv6 server B as a DHCPv6 trusted port to forward response packets.
- Set the other ports of the access device S as DHCPv6 untrusted ports to filter response packets.

16.2.2 Prevention of Forged DHCPv6 Packet Attacks

Scenario

There may exist malicious users on the network who forge DHCPv6 request packets. The packets not only consume available IPv6 addresses of the server but may also snatch IPv6 addresses from legal users. Therefore, such packets on the network must be filtered.

As shown in the following figure, the DHCPv6 request packets sent by the DHCPv6 client will be checked.

- Release packets and decline packets from the client must match those recorded in the internal snooping database.

Figure 16-2

Remarks	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a controlled DHCPv6 server.</p>
----------------	--

Deployment

- Enable DHCPv6 snooping on the access device S for DHCPv6 monitoring.
- Set the port connecting the access device S to the DHCPv6 server as a DHCPv6 trusted port to forward response packets.
- Set the other ports of the access device S as DHCPv6 untrusted ports to filter DHCPv6 packets.

16.2.3 Prevention of IPv6/MAC Spoofing

Scenario

When checking IPv6 packets from the untrusted port, you may check IP address fields only or IP+MAC fields to filter forged IPv6 packets.

As shown in the following figure, IPv6 packets sent from the DHCPv6 client will be checked.

- The source address fields of IPv6 packets must match IPv6 addresses assigned by the DHCPv6 client.
- The source Media Access Control (MAC) addresses of Layer-2 packets must match the client MAC addresses in DHCPv6 request packets of the client.

Figure 16-3

Remarks	<p>S is an access device.</p> <p>A and C are user PCs.</p> <p>B is a controlled DHCPv6 server.</p>
----------------	--

Deployment

- Enable DHCPv6 snooping on the access device S for DHCPv6 monitoring.
- Set all downstream ports on the access device S as DHCPv6 untrusted ports.
- Enable IPv6 Source Guard on the access device S to filter IPv6 packets.
- On the access device S, set the match mode of IPv6 Source Guard as IPv6+MAC to check both MAC fields and IPv6 fields of IPv6 packets.

16.2.4 Prevention of Unauthorized IPv6 Configuration

Scenario

When checking IPv6 packets from untrusted ports, you need to check whether source IPv6 addresses of the packets are consistent with the IPv6 addresses assigned by the DHCPv6.

If the source IPv6 addresses, connection ports, or Layer-2 MAC addresses of IPv6 packets fail to match the assignment records of the DHCPv6 server snooped by the device, the packets should be discarded.

The operating process of the device in the scenario is the same as that in the preceding figure.

Deployment

- See section 16.2.3 "Prevention of IPv6/MAC Spoofing".

16.3 Features

Basic Concepts

↳ DHCPv6 Request Packet

A DHCPv6 request packet is the packet sent from the DHCPv6 client to the DHCPv6 server. It includes DHCPv6 solicit packet, DHCPv6 request packet, DHCPv6 confirm packet, DHCPv6 rebind packet, DHCPv6 release packet, DHCPv6 decline packet, DHCPv6 renew packet, DHCPv6 inform-req packet, and DHCPv6 leasequery packet.

↳ DHCPv6 Response Packet

A DHCPv6 response packet is the packet sent from the DHCPv6 server to the DHCPv6 client. It includes DHCPv6 advertise packet, DHCPv6 reply packet, DHCPv6 reconfigure packet, DHCPv6 relay-reply packet, DHCPv6 leasequery-reply packet, DHCPv6 leasequery-done packet, and DHCPv6 leasequery-data packet.

↳ DHCPv6 Snooping Trusted Port

As the interactive packets used by DHCPv6 to obtain IPv6 addresses or prefixes are multicast packets, there may exist illegal DHCPv6 services affecting IPv6 acquisition, and user information may even be stolen by such illegal services. To prevent such issues, DHCPv6 snooping classifies ports into trusted and untrusted ports, and the devices forwards only the DHCPv6 response packets received by the trusted port and discards all DHCPv6 response packets from the untrusted port. By setting the ports connected to a legal DHCPv6 server as trusted ports and the others as untrusted ports, illegal DHCPv6 servers will be shielded.

On a switch, all switch ports or Layer-2 aggregate ports (APs) are untrusted ports by default, which can be configured as trusted ports.

↳ Filtering DHCPv6 Snooping Request Packets

When DHCPv6 packets are disabled for an individual user, any DHCPv6 packets sent from the user's device shall be shielded. DHCPv6 request packet filtering can be configured on an untrusted port to filter all DHCPv6 request packets received by the port.

↳ VLAN-based DHCPv6 Snooping

DHCPv6 snooping takes effect in the unit of VLAN. If DHCPv6 snooping is enabled by default, the function is enabled on all VLANs of the device. The VLAN on which DHCPv6 snooping takes effect can be flexibly controlled through configuration.

↳ DHCPv6 Snooping User Database

On a DHCPv6 network, a frequently encountered problem is that users may arbitrarily set static IPv6 addresses. Such addresses are difficult to maintain and may conflict with legal user addresses, making the users unable to access the Internet. By snooping the packets exchanged between the client and the server, DHCPv6 snooping forms IPv6 information obtained by users, user MAC, VID, PORT, and lease time into a user record, thus making a DHCPv6 snooping user database to control legal use of IPv6 addresses.

↳ DHCPv6 Option 18 and Option 37

When managing user IP addresses, some network administrators expect to determine the IP addresses to be assigned according to the user locations; that is, they expect to assign IP addresses to users according to the information on the connected network devices, thereby adding user-related device information to DHCP request packets through DHCPv6 option while performing DHCPv6 snooping. The option number for RFC3315 is 18; the option number for RFC4649, the option number used is 37. After the content of Option 18 and Option 37 is parsed on the DHCPv6 server, the server can obtain information of more users according to the content uploaded by Option 18 and option 37 so as to assign IP addresses more accurately.

- Option 18: Interface ID

The default content of Interface ID include the number of the VLAN to which the port receiving request packets from the DHCPv6 client belongs, and the port index (the values of the port index are the slot number and port number); the extension content is a customized character string. Default and extension fillings take effect only for wired interfaces, including switch ports, Layer-2 APs, or Layer-2 encapsulation sub-interfaces.

The Interface ID filling format can be classified into standard and extension formats, only one of which can be used on the same network. When the standard filling format is used, only default content can be filled in for sub-options of Interface ID, as shown in the following figure:

Figure 16-4

To use customized content, the extension filling format can be used. The content filled in by extension can be default or extension content. To distinguish between the content, add a content type field and a content length field of one byte respectively following the sub-option length. For default content, set the content type as 0; for extension content, set the content type as 1.

The format of default content is as follows:

Figure 16-5

The format of extension content is as follows:

Figure 16-6

- Option 37: Remote ID

The default content of Remote ID is the bridge MAC address of the DHCPv6 relay that receives request packets from the DHCPv6 client, and the extension content is a customized character string.

The Remote ID filling format can be classified into standard and extension formats, only one of which can be used on the same network. When the standard filling format is used, only default content are filled in for sub-options of Remote ID, as shown in the following figure:

Figure 16-7

To use customized content, the extension filling format can be used. The content filled in by extension can be default or extension content. To distinguish between the content, add a content type field and a content length field of one byte respectively following the sub-option length. For default content, set the content type as 0; for extension content, set the content type as 1.

The format of default content is as follows:

Figure 16-8

The format of extension content is as follows:

Figure 16-9

● Note

Option 18: The values of port index for Interface ID are the slot number and port number. The port can be a wired switch port, Layer-2 AP, or Layer-2 encapsulation sub-interface. The port number refers to the sequence number of the port in the slot. The port number of a Layer-2 AP is an AP number. For example, the port number of Fa0/10 is 10, the port number of AP 11 is 11, and the port number of WLAN 1 is 1;

Slot numbers are the sequence numbers of all slots on a device (one device in stack mode). The slot number of an AP is the last one. The sequence numbers of slots start from 0. Run the **show slots** command to display the numbers. For example:

Example 1:

```
Nodexon#show slots (only Dev and slot displayed)
Dev Slot
--- ----
1 0 -----> The slot number is 0.
1 1 -----> The slot number is 1.
1 2 -----> The slot number is 2.
```

In this case, the slot number of an AP is 3.

Example 2:

```
Nodexon#show slots (only Dev and slot displayed)
```

```

Dev Slot
--- ----
1  0  -----> The slot number is 0.
1  1  -----> The slot number is 1.
1  2  -----> The slot number is 2.
2  0  -----> The slot number is 3.
2  1  -----> The slot number is 4.
2  2  -----> The slot number is 5.
    
```

In this case, the slot number of an AP is 6.

↘ Illegal DHCPv6 Packet

DHCPv6 snooping checks the validity of DHCPv6 packets passing through the device, discards illegal DHCPv6 packets, records user information, and generates a DHCPv6 snooping binding database for query of other functions. The following packets are considered as illegal DHCPv6 packets.

- DHCPv6 response packets received by untrusted ports. For details, see the section DHCPv6 Response Packet.
- Relayed DHCPv6 packets received by untrusted ports, namely DHCPv6 relay-forw packets and DHCPv6 relay-reply packets.
- DHCPv6 relay-reply packets received by trusted ports. The egress for these packets is an untrusted ports according to the entry.
- DHCPv6 release packets; no corresponding users are found in the DHCPv6 snooping user database according to the Layer-2 source MAC and VID of these packets.
- DHCPv6 release packets. The IPv6 addresses or prefixes of these packets do not exist in the DHCPv6 snooping user database.
- DHCPv6 release packets. The IPv6 addresses or prefixes of these packets all exist in the DHCPv6 snooping user database but the untrusted ports of DHCPv6 release packets are inconsistent with those untrusted ports in the DHCPv6 snooping user database.
- DHCPv6 packets in incorrect formats or incomplete packets.

Overview

Features	Description
Filtering Illegal DHCPv6 Packets	Checks the validity of exchanged DHCPv6 packets, and discards illegal packets (see the preceding section for instructions for illegal packets). Forwards only legal response packets to trusted ports.
Establishing a User Database	Snoops interaction between the client and the server, and generates the DHCPv6 snooping user database to provide a basis for other security filtering modules.

16.3.1 Filtering Illegal DHCPv6 Packets

This function is to check the validity of DHCPv6 packets from untrusted ports, filter the packets according to the types of illegal packets described in Basic Concepts above, and control the transmission scope of packets to prevent malicious users from spoofing.

Working Principle

During snooping, the receipt ports of packets and packet fields are checked to filter the packets; the destination ports of packets are modified to control the transmission scope of packets.

↘ Checking Ports

When receiving DHCPv6 packets, the device first determines whether the port receiving packets is a DHCPv6 trusted port. If the port is a trusted port, the packets will be forwarded without validity check, binding, or prefix record generation. If the port is an untrusted port, validity check is required.

↘ Checking whether Packet Encapsulation and Length are Complete

Check whether the packets are User Datagram Protocol (UDP) packets and the destination port is 546 or 547. Check whether the actual length of a packet matches the length field described in the protocol.

↘ Checking Whether DHCPv6 Packet Field and Packet Type are Correct

Check whether the packets are relayed according to the types of illegal packets described in the preceding section Basic Concepts, and then check whether the restrictions specific to a type of packets are met according to the actual type of packets.

Related Configuration

↘ Enabling Global DHCPv6 Snooping

By default, DHCPv6 snooping is disabled.

Run the [**no**] **ipv6 dhcp snooping** command to enable or disable DHCPv6 snooping.

To enable or disable DHCPv6 snooping on different VLANs, global DHCPv6 snooping must be enabled first.

↘ Setting DHCPv6 Snooping on a VLAN

By default, when global DHCPv6 snooping is enabled, DHCPv6 snooping takes effect on all VLANs.

Run the [**no**] **ipv6 dhcp snooping vlan** command to enable or disable DHCPv6 snooping on a VLAN. The range of command parameter values is the actual range of VLAN numbers.

16.3.2 Establishing a User Database

The packets exchanged between the DHCPv6 client and the DHCPv6 server are snooped, and DHCPv6 snooping binding entries and prefix entries are generated according to the information on legal DHCPv6 packets. All the entries are provided for other security configuration modules as an information list of legal users and a basis for network packet filtering.

Working Principle

During snooping, binding database and prefix database are continuously updated according to the types of DHCPv6 packets.

Generating Binding or Prefix Records

When DHCPv6 reply packets are snooped on a trusted port, client IPv6 addresses or prefixes, client MAC addresses, and lease time fields of the packets are extracted, and a binding or prefix record is generated according to the client port ID recorded by the device (wired interface index), and the client VLAN.

Deleting Binding or Prefix Records

When the recorded lease time is over, or the legal DHCPv6 release/DHCPv6 decline packets sent from the client are snooped, or users run the clear command to delete binding or prefix records, the corresponding binding or prefix records are deleted.

Related Configuration

Enable DHCPv6 snooping without extra configuration.

16.4 Configuration

Configuration	Description and Command	
Configuring Basic DHCPv6 Snooping Functions	 (Mandatory) It is used to establish DHCPv6 snooping.	
	ipv6 dhcp snooping	Enables DHCPv6 snooping.
	ipv6 dhcp snooping binding-delay	Delays assignment of the DHCPv6 snooping binding entries to the hardware filtering entries.
	ipv6 dhcp snooping filter-dhcp-pkt	Enables DHCPv6 request packet filtering.
	ipv6 dhcp snooping vlan	Enables and disables DHCPv6 snooping for specified VLANs.
	ipv6 dhcp snooping database write-delay	Enables the function for regularly saving DHCPv6 snooping binding and prefix records.
	ipv6 dhcp snooping database write-to-flash	Manually saves DHCPv6 snooping binding and prefix records.
	renew ipv6 dhcp snooping database	Manually imports the user records saved in flash to the DHCPv6 snooping user database.
ipv6 dhcp snooping trust	Configures DHCPv6 snooping trusted ports.	

Configuration	Description and Command	
	ipv6 dhcp snooping link-detection	Clears dynamical biding entries on a port when the port is configured into Link Down state.
Configuring Option 18 and Option 37	 (Optional) It is used to optimize assignment of DHCPv6 server addresses.	
	ipv6 dhcp snooping Information option [standard-format]	Adds Option 18 or Option 37 to DHCPv6 request packets. standard-format: Fills in content in a standard format if such keyword exists; otherwise, fills in content in an extension format.
	ipv6 dhcp snooping information option format remote-id [string ASCII-string hostname]	Configures Remote ID in an extension format. string: Indicates that the content filled in is a customized character string. hostname: Indicates that the content filled in is hostname.
	ipv6 dhcp snooping vlan vlan-id information option format-type interface-id string ASCII-string	Configures the customized character string of Interface ID in an extension format.
	ipv6 dhcp snooping vlan vlan-id information option change-vlan-to vlan vlan-id	Configures VLAN mapping for Interface ID in an extension format, which is exclusive from the [no] ipv6 dhcp snooping vlan vlan-id information option format-type interface-id string ASCII-string command.

16.4.1 Configuring Basic DHCPv6 Snooping Functions

Configuration Effect

- Enable DHCPv6 snooping.
- Generate DHCPv6 snooping binding and prefix databases.
- Control the transmission scope of DHCPv6 packets.
- Filter illegal DHCPv6 packets.

Notes

- The port connecting the device to a trusted DHCPv6 server must be set as a trusted port.
- The port on which DHCPv6 snooping takes effect can be a wired switch port, Layer-2 AP or Layer-2 encapsulation sub-interface.
- The Link Down entry clearing function applies only to wired ports.

Configuration Steps

↘ Enabling Global DHCPv6 Snooping

- Mandatory.
- If not specified, configure this function on an access device.

↘ Delaying Assignment of DHCPv6 Snooping Binding Entries to Hardware Filtering Entries

- Configure the function if assignment needs to be delayed. Assignment is not delayed by default.
- If not specified, configure this function on an access device.

↘ Enabling DHCPv6 Request Packet Filtering

- Enable the function if users' DHCPv6 requests need to be restricted on a port.
- If not specified, disable the function on the access device.

↘ Enabling and Disabling VLAN-based DHCPv6 Snooping

- Disable DHCPv6 snooping if the function is not needed on a VLAN.
- If not specified, configure this function on an access device.

↘ Enabling Regular Saving of DHCPv6 Snooping Binding Records

- This function should be enabled if DHCPv6 snooping binding records need to be maintained after the device is restarted.
- If not specified, enable the function on the access device.

↘ Configuring DHCPv6 Trusted Ports

- Mandatory.
- Set the port connecting the device to a trusted DHCPv6 device as a DHCPv6 trusted port.

↘ Enabling and Disabling Clearing of Dynamically Bound Entries When the Port is Configured into Link Down State

- On a stable network, enable the function to release spaces occupied by hardware entries and timely clear the entries on the Link Down port.
- If not specified, disable the function on the access device.

Verification

Enable the device to use DHCPv6 to obtain network configuration parameters.

- Check whether user records are generated in the DHCPv6 snooping binding database.

Related Commands

↘ Enabling and Disabling DHCPv6 Snooping

Command	[no] ipv6 dhcp snooping
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After global DHCPv6 snooping is enabled, run the show ipv6 dhcp snooping command to check whether DHCPv6 snooping is enabled.

↘ Delaying Assignment of the DHCPv6 Snooping Binding Entries to the Hardware Filtering Entries

Command	[no] ipv6 dhcp snooping binding-delay
Parameter Description	seconds: Indicates the time for delaying assignment of binding entries to hardware filtering entries, in the unit of seconds. The value is 0 by default.
Command Mode	Global configuration mode
Usage Guide	By default, dynamically bound entries are added to hardware filtering entries in real time. After the function is configured, the dynamically generated binding entries are bound to hardware filtering entries only when no IPv6 address conflicts are detected within a specified time period.

↘ Configuring a VLAN on Which DHCPv6 Snooping Takes Effect

Command	[no] ipv6 dhcp snooping vlan { <i>vlan-rng</i> { <i>vlan-min</i> [<i>vlan-max</i>] } }
Parameter Description	<i>vlan-rng:</i> Indicates the VLAN scope in which DHCPv6 snooping takes effect. <i>vlan-min:</i> Indicates the lower VLAN limit where DHCPv6 snooping takes effect. <i>vlan-max:</i> Indicates the upper VLAN limit where DHCPv6 snooping takes effect.
Command Mode	Global configuration mode
Usage Guide	DHCPv6 snooping is enabled or disabled on a specified VLAN by configuring the command. This function takes effect only if global DHCPv6 snooping is enabled.

↘ Filtering DHCPv6 Request Packets on a Port

Command	[no] ipv6 dhcp snooping filter-dhcp-pkt
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	All DHCPv6 request packets can be prohibited on the port by configuring the command; that is, all users are prohibited from applying for addresses on the port.

↘ Regularly Writing DHCPv6 Snooping Database Information into Flash

Command	[no] ipv6 dhcp snooping database write-delay [<i>time</i>]
Parameter	<i>time:</i> Indicates the interval for regularly writing the DHCPv6 snooping database into flash.

Description	
Command Mode	Global configuration mode
Usage Guide	The DHCPv6 snooping database can be written into a flash file by configuring the command. The function prevents user information loss after the device restarts. If user information is lost, users have to re-obtain IP addresses for normal communication.

↳ Manually Writing DHCPv6 Snooping Database Information into Flash

Command	ipv6 dhcp snooping database write-to-flash
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Dynamic user information in the DHCPv6 snooping database can be written into a flash file in real time by running the command.

↳ Manually Importing Information in Flash to the DHCPv6 Snooping Binding Database

Command	renew ipv6 dhcp snooping database
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Flash file information can be written into the DHCPv6 snooping database in real time by running the command.

↳ Configuring a Port as a Trusted Port

Command	[no] ipv6 dhcp snooping trust
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	The port connecting to a legal DHCPv6 server is configured as a trusted port by configuring the command. The DHCPv6 response packets received by a trusted port are forwarded, while the DHCPv6 response packets received by an untrusted port are discarded.

Configuration Example

↳ Dynamically obtaining IPv6 addresses through the legal DHCPv6 server on a DHCPv6 client

<p>Scenario Figure 16-10</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Enable DHCPv6 snooping on the access device (Switch B). ● Set the uplink port (Gi 0/1) as a trusted port.
<p>B</p>	<pre>B#configure terminal Enter configuration commands, one per line. End with CNTL/Z. B(config)#ipv6 dhcp snooping B(config)#interface gigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ipv6 dhcp snooping trust B(config-if-GigabitEthernet 0/1)#end</pre>
<p>Verification</p>	<p>Confirm configuration of Switch B.</p> <ul style="list-style-type: none"> ● Confirm whether DHCPv6 snooping is enabled and whether the DHCPv6 snooping trusted port configured is the uplink port. ● On Switch B, check the configuration of DHCP snooping, especial whether the trusted port is correct.

```

GigabitEthernet 0/1

```

Common Errors

- The uplink port is not set as a DHCPv6 trusted port.
- Other access security options are configured on the uplink port, resulting in failure of DHCPv6 trusted port configuration.

16.4.2 Configuring Option 18 and Option 37

Configuration Effect

- The DHCPv6 server can obtain more information during address assignment, thus improving address assignment.
- The option is transparent to the DHCPv6 client, and such function is perception-free to the client.

Configuration Steps

- Run the configuration if the optimization is needed.
- If not specified, enable the function on the device where DHCPv6 snooping is enabled.

Verification

Check the configuration of DHCPv6 snooping to ensure that such function is enabled.

Related Commands

Adding Option18 and Option 37 to DHCPv6 Request Packets

Command	[no] ipv6 dhcp snooping information option [standard-format]
Parameter Description	standard-format : Fills in content in a standard format if such keyword exists; otherwise, fills in content in an extension format.
Command Mode	Global configuration mode
Usage Guide	Information on Option 18 and Option 37 is added to DHCPv6 request packets by configuring the command, and the DHCPv6 server assigns addresses according to information on Option 18 and Option 37.

Setting Option 37 (Remote ID) as a Customized Character String

Command	[no] ipv6 dhcp snooping information option format remote-id { string ASCII-string hostname }
Parameter Description	string ASCII-string : Indicates that the content of Remote ID in an extension format is a customized character string. hostname : Indicates that the content of Remote ID in an extension format is hostname.
Command Mode	Global configuration mode
Usage Guide	Remote ID is configured in an extension format by configuring the command. Remote ID is customized, and the DHCPv6 server assigns addresses according to information on Option 37.

Setting Option 18 (Interface ID) as a Customized Character String

Command	[no] ipv6 dhcp snooping vlan <i>vlan-id</i> information option format-type <i>interface-id</i> string ASCII-string
Parameter Description	<i>vlan-id</i> : Indicates the VLAN to which DHCPv6 request packets belong. <i>ASCII-string</i> : Indicates the user-customized content to be filled in for Interface-ID.
Command Mode	Interface configuration mode
Usage Guide	Customized character strings of Interface ID are configured in an extension format by configuring the command, and the DHCPv6 server assigns addresses according to information on Option 18.

Setting Option 18 (Interface ID) as a Modified VLAN

Command	[no] ipv6 dhcp snooping vlan <i>vlan-id</i> information option change-vlan-to vlan <i>vlan-id</i>
Parameter Description	<i>vlan-id</i> (the first one): Indicates the VLAN to which DHCPv6 request packets belong. <i>vlan-id</i> (the second one): Indicates the VLAN after modification.
Command Mode	Interface configuration mode
Usage Guide	Interface ID is configured as VLAN mapping in an extension format by configuring the command, and the DHCPv6 server assigns addresses according to information on Option 18.

Configuration Example

Displays all dynamically bound entries in the DHCPv6 snooping binding database.	show ipv6 dhcp snooping binding
Displays all entries in the DHCPv6 snooping prefix database.	show ipv6 dhcp snooping prefix
Displays the counters of DHCPv6 snooping handling packets.	show ipv6 dhcp snooping statistics
Displays all statically bound entries added manually and all dynamically bound entries in the DHCPv6 snooping binding database.	show ipv6 source binding

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs DHCPv6 snooping events.	debug snooping ipv6 event
Disables debugging of DHCPv6 snooping events.	no debug snooping ipv6 event
Debugs DHCPv6 snooping packets.	debug snooping ipv6 packet
Disables debugging of DHCPv6 snooping packets.	no debug snooping ipv6 packet

17 Configuring ARP Check

17.1 Overview

The Address Resolution Protocol (ARP) packet check filters all ARP packets under ports (including wired layer-2 switching ports, layer-2 aggregate ports (APs), and layer-2 encapsulation sub-interfaces) and discards illegal ARP packets, so as to effectively prevent ARP deception via networks and to promote network stability. On devices supporting ARP check, illegal ARP packets in networks will be ignored according to the legal user information (IP-based or IP-MAC based) generated by security application modules such as IP Source Guard, global IP+MAC binding, 802.1X authentication, GSN binding, Web authentication and port security.

Figure 17-1

The above figure shows that security modules generate legal user information (IP-based or IP-MAC based). ARP Check uses the information to detect whether the Sender IP fields or the <Sender IP, Sender MAC>fields in all ARP packets at ports matches those in the list of legal user information. If not, all unlisted ARP packets will be discarded.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

17.2 Applications

Application	Description
Filtering ARP packets in Networks	Illegal users in networks launch attacks using forged ARP packets.

17.2.1 Filtering ARP Packets in Networks

Scenario

Check ARP packets from distrusted ports and filter out ARP packets with addresses not matching the results assigned by the DHCP server.

For example, in the following figure, the ARP packets sent by DHCP clients are checked.

- The ports receiving ARP packets, the source MAC addresses of ARP packets, and the source IP addresses of ARP packets shall be consistent with the snooped DHCP-assigned records.

Figure 17-2

Remarks:	S is an access device. A and C are user PCs.
-----------------	---

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all the downlink ports on S as DHCP distrusted ports.
- Enable IP Source Guard and ARP Check on all distrusted ports on S to realize ARP packet filtration.

17.3 Features

Basic Concepts

Compatible Security Modules

Presently, the ARP Check supports the following security modules.

- IP-based: IP-based mode: port security, and static configuration of IP Source Guard.
- IP-MAC based: IP-MAC based mode: port security, global IP+MAC binding, 802.1X authorization, IP Source Guard, GSN binding, and Web authentication.

Two Modes of APR Check

The ARP Check has two modes: Enabled and Disabled. The default is Enabled.

1. Enabled Mode

Through ARP Check, ARP packets are detected based on the IP/IP-MAC based binding information provided by the following modules.

- Global IP-MAC binding
- 802.1X authorization
- IP Source Guard
- GSN binding
- Port security
- Web authentication
- Port security IP+MAC binding or IP binding

 When only ARP Check is enabled on a port but the above-mentioned modules are not enabled, legal user information cannot be generated, and thereby all ARP packets from this port will be discarded.

 When the ARP Check and VRRP functions are enabled on an interface, if the physical IP address and virtual IP address of the interface can be used as the gateway address, the physical IP address and VRRP IP address need to be permitted to pass. Otherwise, ARP packets sent to the gateway will be filtered out.

2. Disabled Mode

ARP packets on a port are not checked.

Overview

Feature	Description
Filtering ARP Packets	Check the source IP and source MAC addresses of ARP packets to filter out illegal ARP packets.

17.3.1 Filtering ARP Packets

Enable ARP Check on specified ports to realize filtration of illegal ARP packets.

Working Principle

A device matches the source IP and source MAC addresses of the ARP packets received at its ports with the legal user information of the device. With successful matching, packets will be transferred, or otherwise they will be discarded.

Related Configuration

↘ Enabling ARP Check on Ports

By default, the ARP Check is disabled on ports.

Use the **arp-check** command to enable ARP Check.

Unless otherwise noted, this function is usually configured on the ports of access devices.

17.4 Configuration

Configuration	Description and Command		
Configuring ARP Check	 (Mandatory) It is used to enable APR Check.		
	<table border="1"> <tr> <td>arp-check</td> <td>Enables ARP Check.</td> </tr> </table>	arp-check	Enables ARP Check.
arp-check	Enables ARP Check.		

17.4.1 Configuring ARP Check

Configuration Effect

- Illegal ARP packets are filtered out.

Notes

- When ARP Check is enabled, the number of policies or users of related security applications may decrease.
- ARP Check cannot be configured on mirrored destination ports.
- ARP Check cannot be configured on the trusted ports of DHCP Snooping.
- ARP Check cannot be configured on global IP+MAC exclude ports.
- ARP Check can be enabled only on wired switching ports, layer-2 APs, layer-2 encapsulation sub-interfaces. Enable ARP check for the wired in interface configuration mode

Configuration Steps

↘ Enabling ARP Check

- (Mandatory) The function is disabled by default. To use the ARP Check function, an administrator needs to run a command to enable it.

Verification

- Use the **show run** command to display the system configuration.
- Use the **show interface** { *interface-type interface-number* } **arp-check list** command to display filtering entries.

Related Commands

↘ Enabling ARP Check

Command	arp-check

Parameter Description	N/A
Command	Interface configuration mode
Usage Guide	Generate ARP filtration information according to the legal user information of security application modules to filter out illegal ARP packets in networks.

Configuration Example

 The following configuration example introduces only ARP Check related configurations.

Enabling ARP Check on ports

Configuration Steps	<ul style="list-style-type: none">● Enable ARP Check. Restricted ARP packets must conform to entries of IP Source Guard, port security, or global IP+MAC binding.
----------------------------	---

17.5 Monitoring

Displaying

Description	Command
Displays the effective ARP Check list based on ports.	show interface [<i>interface-type interface-number</i>] arp-checklist

18 Configuring Dynamic ARP Inspection

18.1 Overview

Dynamic Address Resolution Protocol (ARP) inspection (DAI) checks the validity of received ARP packets. Invalid ARP packets will be discarded.

DAI ensures that only valid ARP packets can be forwarded by devices. DAI mainly performs the following steps:

- Intercepts all ARP request packets and ARP reply packets on untrusted ports in the virtual local area networks (VLANs) where the DAI function is enabled.
- Checks the validity of intercepted ARP packets according to user records stored in a security database.
- Discards the ARP packets that do not pass the validity check.
- Sends the ARP packets that pass the validity check to the destination.
- The DAI validity criteria are the same as those of ARP Check. For details, see the *Configuring ARP Check*.

DAI and ARP Check have same functions. The only difference is that DAI takes effect by VLAN whereas ARP Check takes effect by port.

Protocols and Standards

- RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

18.2 Applications

Application	Description
ARP Spoofing Prevention	Prevent ARP spoofing that is mounted by taking advantage of ARP defects.

18.2.1 ARP Spoofing Prevention

Scenario

Due to inherent defects, ARP does not check the validity of received ARP packets. Attackers can take advantage of the defects to mount ARP spoofing. A typical example is man-in-the-middle (MITM) attack. See Figure 18-1.

Figure 18-1

Remarks	<p>Device S is a Nodexon access switch enabled with DAI.</p> <p>User A and User B are connected to Device S, and they are in the same subnet.</p> <p>User C is a malicious user connected to Device S.</p> <p>IP A and MAC A are the IP address and MAC address of User A.</p> <p>IP B and MAC B are the IP address and MAC address of User B.</p> <p>IP C and MAC C are the IP address and MAC address of User C.</p>
----------------	--

When User A needs to initiate network layer communication with User B, User A broadcasts an ARP request in the subnet to query the MAC address of User B. Upon receiving the ARP request packet, User B updates its ARP cache with IP A and MAC A, and sends an ARP reply. Upon receiving the ARP reply packet, User A updates its ARP cache with IP B and MAC B.

In this model, User C can make the ARP entry mapping between User A and User B incorrect by continuously broadcasting ARP reply packets to the network. The reply packets contain IP A, IP B, and MAC C. After receiving these reply packets, User A stores the ARP entry (IP B, MAC C), and User B stores the ARP entry (IP A, MAC C). As a result, the communication between User A and User B is directed to User C, without the knowledge of User A and User B. Here User C acts as the man in the middle by modifying received packets and forwarding them to User A or User B.

If Device S is enabled with DAI, it will filter out forged ARP packets to prevent ARP spoofing as long as the IP addresses of User A and User B meet the validity criteria described in section 18.1 Overview. Figure 18-2 shows the working process of DAI.

Figure 18-2

Remarks	<p>Device S is a Nodexon access switch enabled with DAI.</p> <p>User A and User B are connected to Device S, and they are in the same subnet.</p> <p>User C is a malicious user connected to Device S.</p> <p>IP A and MAC A are the IP address and MAC address of User A.</p> <p>IP B and MAC B are the IP address and MAC address of User B.</p> <p>IP C and MAC C are the IP address and MAC address of User C.</p>
----------------	--

The ARP packets of User A and User B are forwarded normally by Device S. The forged ARP packets of User C are discarded because the packets do not match the records in the security database of Device S.

Deployment

- Enable DHCP Snooping on Device S.
- Enable DAI and IP Source Guard on Device S.

18.3 Features

Basic Concepts

Trust Status of Ports and Network Security

ARP packet check is performed according to the trust status of ports. DAI considers packets received from trusted ports as valid without checking their validity, but it checks the validity of packets received from untrusted ports.

For a typical network configuration, you should configure Layer-2 ports connected to network devices as trusted ports, and configure Layer-2 ports connected to hosts as untrusted ports.

 Network communication may be affected if a Layer-2 port connected to a network device is configured as an untrusted port.

Overview

Feature	Description
Invalid ARP Packet Filter	Checks the source IP addresses and MAC addresses of ARP packets to filter out invalid packets.
DAI Trusted Port	Permits the ARP packets received from specific ports to pass through without checking their validity.

18.3.1 Invalid ARP Packet Filter

Enable DAI in a specific VLAN to filter out invalid ARP packets. The DAI validity criteria are the same as those of ARP Check.

Working Principle

Upon receiving an ARP packet, the device matches the IP address and MAC address of the packet with the valid user records in its security database. If the packet matches a record, it will be forwarded normally. If it does not match any record, it will be discarded.

DAI and ARP Check use the same set of valid user records. For details, see the packet validity check description in the *Configuring ARP Check*.

Related Configuration

↳ Enabling DAI in a VLAN

By default, DAI is disabled in VLANs.

Run the **ip arp inspection vlan** *vlan-id* command to enable DAI in a specific VLAN.

 After DAI is enabled in a VLAN, DAI may not take effect on all ports in the VLAN. A DHCP Snooping trusted port does not perform DAI check.

↳ Disabling DAI in a VLAN

By default, DAI is disabled in VLANs.

After DAI is enabled in a VLAN, you can run the **no ip arp inspection vlan** *vlan-id* command to disable DAI.

 Disabling DAI in a VLAN does not mean disabling packet validity check on all ports in the VLAN. The ports with ARP Check effective still check the validity of received ARP packets.

18.3.2 DAI Trusted Port

Configure specific device ports as DAI trusted ports.

Working Principle

The validity of ARP packets received from trusted ports is not checked. The ARP packets received from untrusted ports are checked against the user records in a security database.

Related Configuration

↳ Configuring DAI Trusted Ports

By default, all ports are untrusted ports.

Run the **ip arp inspection trust** command to set ports to trusted state.

 A port already enabled with access security control cannot be set to DAI trusted state. To set the port to DAI trusted state, first disable access security control.

 In normal cases, uplink ports (ports connected to network devices) can be configured as DAI trusted ports.

18.4 Configuration

Configuration	Description and Command	
Configuring DAI	 (Optional) It is used to enable ARP packet validity check.	
	<code>ip arp inspection vlan</code>	Enables DAI.
	<code>ip arp inspection trust</code>	Configures DAI trusted ports.

18.4.1 Configuring DAI

Configuration Effect

- Check the validity of incoming ARP packets in a specific VLAN.

Notes

- DAI cannot be enabled on DHCP Snooping trusted ports.

Configuration Steps

▾ Enabling ARP Packet Validity Check in a Specific VLAN

- Optional.
- Perform this configuration when you need to enable ARP packet validity check on all ports in a VLAN.
- Perform this configuration on Nodexon access devices unless otherwise specified.

▾ Configuring DAI Trusted Ports

- Optional.
- It is recommended to configure uplink ports as DAI trusted ports after DAI is enabled. Otherwise, the uplink ports enabled with other security features and set to trusted state accordingly may filter out valid ARP packets due to the absence of DAI user entries.
- Perform this configuration on Nodexon access devices unless otherwise specified.

▾ Configuring the ARP Packet Reception Rate

- For details, see the rate limit command description in the *Configuring the NFPP*.

Verification

- Construct invalid ARP packets by using a packet transfer tool and check whether the packets are filtered out on DAI-enabled devices.
- Run the **show** command to check the device configuration.

Related Commands

➤ Enabling DAI

Command	ip arp inspection vlan { <i>vlan-id</i> <i>word</i> }
Parameter	<i>vlan-id</i> : Indicates a VLAN ID.
Description	<i>word</i> : Indicates the VLAN range string, such as 1, 3–5, 7, and 9–11.
Command Mode	Global configuration mode
Usage Guide	N/A

➤ Configuring DAI Trusted Ports

Command	ip arp inspection trust
Parameter	N/A
Description	
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure a DAI trusted port so that the ARP packets received by the port can pass through without validity check.

Configuration Example

➤ Allowing Users' PCs to Use only Addresses Allocated by a DHCP Server to Prevent ARP Spoofing

<p>Scenario Figure 18-3</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ⚠ Enable DHCP Snooping on the access switch (Switch A) and configure its uplink port (GigabitEthernet 0/3) connected to the valid DHCP server as a trusted port. ⚠ Enable IP Source Guard on Switch A. ⚠ Enable DAI.
<p>Switch A</p>	<pre>A#configure terminal Enter configuration commands, one per line. End with CNTL/Z. A(config)#vlan 2</pre>

	<pre>A(config-vlan)#exit A(config)#interface range gigabitEthernet 0/1-2 A(config-if-range)#switchport access vlan 2 A(config-if-range)#ip verify source A(config-if-range)#exit A(config)#ip dhcp snooping A(config)#ip arp inspection vlan 2 A(config)#interface gigabitEthernet 0/3 A(config-if-GigabitEthernet 0/3)#switchport access vlan 2 A(config-if-GigabitEthernet 0/3)#ip dhcp snooping trust A(config-if-GigabitEthernet 0/3)#ip arp inspection trust</pre>
Verification	<ul style="list-style-type: none"> ● Check whether DHCP Snooping, IP Source Guard, and DAI are enabled and whether trusted ports are configured correctly. ● Check whether the uplink port on Switch A is a DHCP Snooping trusted port. ● Check whether DAI is enabled successfully in the VLAN and the uplink ports are DAI trusted ports.
Switch A	<pre>A#show running-config A#show ip dhcp snooping A#show ip arp inspection vlan</pre>

Common Errors

- A port with security control enabled is configured as a DAI trusted port.

18.5 Monitoring

Displaying

Description	Command
Displays the DAI state of a specific VLAN.	show ip arp inspection vlan [<i>vlan-id</i> <i>word</i>]
Displays the DAI configuration state of each Layer-2 port.	show ip arp inspection interface

19 Configuring IP Source Guard

19.1 Overview

i The IP Source Guard function realizes hardware-based IP packet filtering to ensure that only the users having their information in the binding database can access networks normally, preventing users from forging IP packets.

19.2 Applications

Application	Description
Guarding Against IP/MAC Spoofing Attack	In network environments, users set illegal IP addresses and malicious users launch attacks through forging IP packets.

19.2.1 Guarding Against IP/MAC Spoofing Attack

Scenario

Check the IP packets from DHCP untrusted ports. Forged IP packets will be filtered out based on the IP or IP-MAC field.

For example, in the following figure, the IP packets sent by DHCP clients are checked.

- The Source IP Address fields of IP packets should match DHCP-assigned IP addresses.
- The Source MAC Address fields of layer-2 packets should match the MAC addresses in DHCP request packets from clients.

Figure 19-1

Remarks: S is a network access server (NAS).
A and C are user PCs.
B is a DHCP server within the control area.

Deployment

- Enable DHCP Snooping on S to realize DHCP monitoring.
- Set all downlink ports on S as DHCP untrusted ports.
- Enable IP Source Guard on S to realize IP packet filtering.
- Enable IP-MAC match mode for IP Source Guard on S, filtering IP packets based on IP and MAC addresses.

19.3 Features

Basic Concepts

↘ Source IP Address

Indicate the source IP address field of an IP packet.

↘ Source MAC Address

Indicate the source MAC address field of an IP packet.

↘ IP-based Filtering

Indicate a policy of IP packet filtering, where only the source IP addresses of all IP packets (except DHCP packets) passing through a port are checked. It is the default filtering policy of IP Source Guard.

↘ IP-MAC based Filtering

A policy of IP packet filtering, where both the source IP addresses and source MAC addresses of all IP packets are checked, and only those user packets with these IP addresses and MAC addresses existing in the binding database are permitted.

↘ Address Binding Database

As the basis of security control of the IP Source Guard function, the data in the address binding database comes from two ways: the DHCP Snooping binding database and static configuration. When IP Source Guard is enabled, the data of the DHCP Snooping binding database is synchronized to the address binding database of IP Source Guard, so that IP packets can be filtered strictly through IP Source Guard on a device with DHCP Snooping enabled.

↘ Excluded VLAN

By default, when IP Source Guard is enabled on a port, it is effective to all the VLANs under the port. Users may specify excluded VLANs, within which IP packets are not checked and filtered, which means that such IP packets are not controlled by IP Source Guard. At most 32 excluded VLANs can be specified for a port.

Overview

Feature	Description
Checking Source Address Fields of Packets	Filter the IP packets passing through ports by IP-based or IP-MAC based filtering.

19.3.1 Checking Source Address Fields of Packets

Filter the IP packets passing through ports based on source IP addresses or on both source IP addresses and source MAC addresses to prevent malicious attack by forging packets. When there is no need to check and filter IP packets within a VLAN, an excluded VLAN can be specified to release such packets.

Working Principle

When IP Source Guard is enabled, the source addresses of packets passing through a port will be checked. The port can be a wired switching port, a layer-2 aggregate port (AP), or a layer-2 encapsulation sub-interface. Such packets will pass the port only when the source address fields of the packets match the set of the address binding records generated by DHCP Snooping, or the static configuration set by the administrator. There are two matching modes as below.

↘ IP-based Filtering

Packets are allowed to pass a port only if the source IP address fields of them belong to the address binding database.

↘ IP-MAC Based Filtering

Packets are allowed to pass a port only when both the layer-2 source MAC addresses and layer-3 source IP addresses of them match an entry in the address binding database.

↘ Specifying Excluded VLAN

Packets within such a VLAN are allowed to pass a port without check or filtering.

Related Configuration

↘ Enabling IP Source Guard on a Port

By default, the IP Source Guard is disabled on ports.

It can be enabled using the **ip verify source** command.

-
- i** Usually IP Source Guard needs to work with DHCP Snooping. Therefore, DHCP Snooping should also be enabled. DHCP Snooping can be enabled at any time on Nodexon devices, either before or after IP Source Guard is enabled.
-

↘ Configuring a Static Binding

By default, legal users passing IP Source Guard check are all from the binding database of DHCP Snooping.

Bound users can be added using the **ip source binding** command.

↘ Specifying an Excluded VLAN

By default, IP Source Guard is effective to all the VLANs under a port.

Excluded VLANs may be specified which are exempted from IP Source Guard using the **ip verify source exclude-vlan** command.

-
- i** Excluded VLANs can be specified only after IP Source Guard is enabled on a port. Specified excluded VLANs will be deleted automatically when IP Source Guard is disabled on a port.
-

 The above-mentioned port can be a wired switching port, a layer-2 AP port or a layer-2 encapsulation sub-interface..

19.4 Configuration

Configuration	Description and Command	
Configuring IP Source Guard	 (Mandatory) It is used to enable IP Source Guard.	
	ip verify source	Enables IP Source Guard on a port.
	ip source binding	Configures a static binding.
	ip verify source exclude-vlan	Specifies an excluded VLAN for IP Source Guard.

19.4.1 Configuring IP Source Guard

Configuration Effect

- Check the source IP addresses of input IP packets.

Notes

- When IP Source Guard is enabled, IP packets forwarding may be affected. In general case, IP Source Guard is enabled together with DHCP Snooping.
- IP Source Guard cannot be configured on the trusted ports controlled by DHCP Snooping.
- IP Source Guard cannot be configured on the global IP+MAC exclusive ports.
- IP Source Guard can be configured and enabled only on wired switch ports, Layer-2 AP ports, Layer-2 encapsulation sub-ports. In a wired access scenario, it is supposed to be configured in the interface configuration mode.

Configuration Steps

- Enable DHCP Snooping.
- Enable IP Source Guard.

Verification

Use the monitoring commands to display the address binding database of IP Source Guard.

Related Commands

↳ Enabling IP Source Guard on a Port

Command	ip verify source [port-security]
Parameter	port-security: Enable IP-MAC based filtering.
Description	
Command	Interface configuration mode

Usage Guide	Detection of users based on IP address or both IP and MAC addresses can be realized by enabling IP Source Guard for a port.
--------------------	---

↘ Configuring a Static Binding

Command	ip source binding <i>mac-address</i> { vlan <i>vlan-id</i> } <i>ip-address</i> { interface <i>interface-id</i> ip-mac ip-only }
Parameter Description	mac-address: The MAC address of a static binding vlan-id: The VLAN ID of a static binding. It indicates the outer VLAN ID of a QINQ-termination user. ip-address: The IP address of a static binding <i>interface-id:</i> The Port ID (PID) of a static binding ip-mac: IP-MAC based mode ip-only: IP-based mode
Configuration Mode	Global configuration mode
Usage Guide	Through this command, legitimate users can pass IP Source Guard detection instead of being controlled by DHCP.

↘ Specifying an Exception VLAN for IP Source Guard

Command	ip verify source exclude-vlan <i>vlan-id</i>
Parameter Description	vlan-id: A VLAN ID exempted from IP Source Guard on a port
Command	Interface configuration mode
Usage Guide	By using this command, the specified VLANs under a port where IP Source Guard function is enabled can be exempted from check and filtering.

Configuration Example

↘ Enabling IP Source Guard on Port 1

Configuration Steps	<ul style="list-style-type: none"> ● Enable DHCP Snooping. ● Enable IP Source Guard.
	<pre>Nodexon(config)# interface GigabitEthernet 0/1 Nodexon(config-if-GigabitEthernet 0/1)# ip verify source Nodexon(config-if-GigabitEthernet 0/1)# end</pre>
Verification	Displays the address filtering table of IP Source Guard.
	<pre>Nodexon# show ip verify source</pre>

↘ Configuring a Static Binding

19.5 Monitoring

Displaying

Description	Command
Displays the address filtering table of IP Source Guard.	show ip verify source [interface <i>interface-id</i>]
Displays the address binding database of IP Source Guard.	show ip source binding

20 Configuring IPv6 Source Guard

20.1 Overview

IPv6 Source Guard binding allows IPv6 packets to be filtered by hardware so as to ensure that only the users having corresponding information in the IPv6 packet hardware filtering database can access the Internet, thus preventing users from configuring IP addresses without authorization or fabricating IPv6 packets.

20.2 Applications

Application	Description
Prevention of IPv6/MAC Spoofing	There are malicious users on a network who fabricate IPv6 packets to launch an attack.

20.2.1 Prevention of IPv6/MAC Spoofing

Scenario

When checking the IPv6 packets from the untrusted DHCPv6 ports, you may check IPv6 fields only or IPv6+MAC fields, thereby filtering fabricated IPv6 packets.

As shown in the following figure, IPv6 packets sent from the Dynamic Host Configuration Protocol version 6 (DHCPv6) client will be checked.

- The source address fields of IPv6 packets must match IPv6 addresses assigned by the DHCPv6 client.
- The source media access control (MAC) addresses of Layer-2 packets must match those assigned by DHCPv6 Snooping to hardware filtering records.

Figure 20-1

Remarks	S is an access device. A and C are user PCs. B is a controlled DHCPv6 server.
----------------	---

Deployment

- Enable DHCPv6 Snooping on the access device S for DHCPv6 monitoring.
- Set all the downstream interfaces on the access device S as untrusted DHCPv6 ports.
- On the access device S, enable IPv6 Source Guard for IPv6 packet filtering.
- On the access device S, set the match mode of IPv6 Source Guard as IPv6+MAC for checking MAC fields and IPv6 fields of IPv6 packets.

20.3 Features

Basic Concepts

↳ Source IPv6

Indicates the source IPv6 address fields of IPv6 packets

↳ Source MAC

Indicates the source MAC address fields of Layer-2 packets

↳ Source IPv6-based Filtering

The source IPv6-based filtering policy checks only the source IPv6 addresses of all IPv6 packets (except DHCP packets) passing through the interface. The source IPv6-based filtering policy is the default filtering policy of IPv6 Source Guard.

↳ Source IPv6+Source MAC-based Filtering

The source IPv6-based filtering policy checks the source IPv6+source MAC of all IPv6 packets, and only the user packets saved in the database for binding user records are allowed to pass through.

↳ Database for Binding User Records

The database for binding user records is the basis for IPv6 Source Guard security control. Currently, the data in the database binding user records come from the following two sources. One is the DHCPv6 Snooping binding database. After IPv6 Source Guard is enabled, the information in the DHCPv6 Snooping binding database is synchronized to the user binding database of IPv6 Source Guard so that IPv6 Source Guard can filter the IPv6 packets of the client on the device where DHCPv6 Snooping is enabled. The other is users' static configuration.

Overview

Feature	Description
Checking the Source Address Fields of Packets	Filters the IPv6 packets passing through the interface based on source IPv6 or source IPv6+source MAC.

20.3.1 Checking the Source Address Fields of Packets

Filter the IPv6 packets transiting the port based on source IPv6 or source IPv6+source MAC, thereby preventing malicious users from fabricating packets to launch an attack.

Working Principle

After IPv6 Source Guard is enabled, the device checks the source addresses of the packets passing through the port. The port can be a wired switch port, Layer-2 aggregate port (AP) or Layer-2 encapsulation sub interface. Only the packets whose source address fields match the user binding record set generated by DHCPv6 Snooping or the user set statically configured by the administrator can pass through the port. There are two matching methods:

Source IPv6 Address-based Filtering

If IPv6 fields of a packet belong to the identity association in the user binding records, the packet is allowed to pass through the port.

IPv6+MAC Address-based Filtering

Only when Layer-2 MAC and Layer-3 IPv6 of a packet completely match a certain record in the set of authenticated users can the packet pass through the port.

Related Configuration

Enabling IPv6 Source Guard on a Port

By default, IPv6 Source Guard is disabled on a port.

IPv6 Source Guard of the port can be enabled or disabled by running the **ipv6 verify source** command.

- Typically, DHCPv6 Snooping is used together with IPv6 Source Guard, so DHCPv6 Snooping needs to be enabled. Timing for enabling DHCPv6 Snooping is not limited on Nodexon devices. You can enable DHCPv6 Snooping before or

after IPv6 Source Guard is enabled.

Configuring Static IPv6 Source Guard Users

By default, all sets of authenticated users checked by IPv6 Source Guard are from the bound users of DHCPv6 Snooping.

Run the **ipv6 source binding** command to add extra user binding records.

20.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring IPv6 Source Guard	 (Mandatory) It is used to enable IPv6 Source Guard.	
	ipv6 verify source	Enables IPv6 Source Guard on a port.
	ipv6 source binding	Configure statically bound users.

20.4.1 Configuring IPv6 Source Guard

Configuration Effect

- Check the source IPv6 fields entered into IPv6 packets.

Notes

- IPv6 Source Guard is based on DHCPv6 Snooping; that is to say, interface-based IPv6 Source Guard takes effect only on the untrusted ports controlled by DHCPv6 Snooping. If configured on trusted ports or the interfaces on VLANs not controlled by DHCPv6 Snooping, the function will not take effect.

Configuration Steps

- Enable DHCPv6 Snooping.
- Enable IPv6 Source Guard.

Verification

Use the monitoring command provided by the device to view the user filtering entries of IPv6 Source Guard.

Related Commands

↳ Enabling IPv6 Source Guard on a Port

Command	ipv6 verify source [port-security]
Parameter Description	port-security: Configures IPv6 Source Guard to perform IPv6+MAC-based detection.
Command Mode	Interface mode
Usage Guide	By enabling IPv6 Source Guard on a port through this command, you can detect users based on IPv6 or IPv6+MAC.

↳ Adding Information on Static Users to Ipv6 Source Address Binding Database

Command	ipv6 source binding mac-address vlan vlan-id ipv6-address { interface interface-id ip-mac ip-only }
Parameter Description	<p>mac-address: Indicates the MAC address of a statically added user.</p> <p>vlan-id: Indicates the VLAN ID of a statically added user.</p> <p>ipv6-address: Indicates the IPv6 addresses of a statically added user.</p> <p>interface-id: Indicates the wired access interface for a statically added user.</p> <p>wlan-id: Indicates the wireless access WLAN for a statically added user.</p> <p>ip-mac: Indicates that the global binding mode is IPv6+MAC binding mode.</p>

	ip-only: Indicates that the global binding mode is IPv6 binding mode only.
Command Mode	Global configuration mode
Usage Guide	By running this command, some users can pass the check of IPv6 Source Guard without being controlled by DHCPv6.

Configuration Example

▾ Enabling IPv6 Source Guard on a Port

Configuration Steps	<ul style="list-style-type: none"> ● Enable DHCPv6 Snooping.

21 Configuring Gateway-targeted ARP Spoofing Prevention

21.1 Overview

Gateway-targeted Address Resolution Protocol (ARP) spoofing prevention effectively prevents gateway-targeted ARP spoofing by checking on the logical port whether the source IP addresses of ARP packets (Sender IP fields of ARP packets) are the self-configured gateway IP addresses.

Protocols and Standards

RFC 826: Ethernet Address Resolution Protocol

21.2 Applications

Application	Description
Typical Application of Gateway-targeted ARP Spoofing Prevention	Blocks ARP spoofing packets with forged gateway address and intranet server IP addresses to ensure that users can access the Internet.

21.2.1 Typical Application of Gateway-targeted ARP Spoofing Prevention

Scenario

- PC users access the office server through the access device Switch A, and connect to external networks through the gateway.
- If any users legally use forged gateway IP addresses or server IP addresses to perform ARP spoofing, the other users cannot access the Internet and the server.
- The ARP spoofing packets with forged gateway address and intranet server IP addresses must be blocked to ensure that users can access the Internet.

Figure 21-1 Typical Topology of Gateway-targeted ARP Spoofing Prevention

Deployment

- On the access switch (Switch A), enable gateway-targeted spoofing prevention on the ports (Gi 0/3 and Gi 0/4 in this case) directly connected to the PC. The gateway addresses include intranet gateway address and intranet server address.

21.3 Features

Basic Concepts

↳ ARP

ARP is a TCP/IP protocol that obtains physical addresses according to IP addresses. Its function is as follows: The host broadcasts ARP requests to all hosts on the network and receives the returned packets to determine physical addresses of the target IP addresses, and saves the IP addresses and hardware addresses in the local ARP cache, which can be directly queried in response to future requests. On the same network, all the hosts using the ARP are considered as mutually trustful to each other. Each host on the network can independently send ARP response packets; the other hosts receive the response packets and record them in the local ARP cache without detecting their authenticity. In this way, attackers can send forged ARP response packets to target hosts so that the messages sent from these hosts cannot reach the proper host or reach a wrong host, thereby causing ARP spoofing.

↳ Gateway-targeted ARP Spoofing

When User A sends an ARP packet requesting the media access control (MAC) address of a gateway, User B on the same VLAN also receives this packet, and User B can send an ARP response packet, passing off the gateway IP address as the source IP address of the packet, and User B's MAC address as the source MAC address. This is called gateway-targeted

ARP spoofing. After receiving the ARP response, User A regards User B's machine as the gateway, so all the packets sent from User A to the gateway during communication will be sent to User B. In this way, User A's communications are intercepted, thereby causing ARP spoofing.

Overview

Feature	Description
Gateway-targeted ARP Spoofing Prevention	Blocks ARP spoofing packets with forged gateway address and intranet server IP addresses to ensure that users can access the Internet.

21.3.1 Gateway-targeted ARP Spoofing Prevention

Working Principle

▾ Gateway-targeted Spoofing Prevention

Gateway-targeted ARP spoofing prevention effectively prevents ARP spoofing aimed at gateways by checking on the logical port whether the source IP addresses of ARP packets are the self-configured gateway IP addresses. If an ARP packet uses the gateway address as the source IP address, the packet will be discarded to prevent users from receiving wrong ARP response packets. If not, the packet will not be handled. In this way, only the devices connected to the switch can send ARP packets, and the ARP response packets sent from the other PCs which pass for the gateway are filtered by the switch.

Related Configuration

▾ Configuring Gateway-targeted Spoofing Prevention Addresses

- By default, no gateway-targeted ARP spoofing prevention address is configured.
- Run the **anti-arp-spoofing ip** command to configure the gateway-targeted ARP spoofing prevention addresses.

21.4 Configuration

Configuration	Description and Command
Configuring Gateway-targeted Spoofing Prevention	 Optional.
	anti-arp-spoofing ip Configures gateway-targeted ARP spoofing prevention on the logical port and specifies the gateway IP address.

21.4.1 Configuring Gateway-targeted Spoofing Prevention

Configuration Effect

Enable gateway-targeted ARP spoofing prevention.

Configuration Steps

➤ **Configuring Gateway-targeted Spoofing Prevention**

- Gateway-targeted ARP spoofing prevention is mandatory. It must be enabled.

Verification

- Run the **show run** command to check configuration.
- Run the **show anti-arp-spoofing** command to display all data on gateway-targeted ARP spoofing prevention.

Related Commands

22 Configuring NFPP

22.1 Overview

Network Foundation Protection Policy (NFPP) provides guards for switches.

Malicious attacks are always found in the network environment. These attacks bring heavy burdens to switches, resulting in high CPU usage and operational troubles. These attacks are as follows:

Denial of Service (DoS) attacks may consume lots of memory, entries, or other resources of a switch, which will cause system service termination.

Massive attack traffic is directed to the CPU, occupying the entire bandwidth of the CPU. In this case, normal protocol traffic and management traffic cannot be processed by the CPU, causing protocol flapping or management failure. The forwarding in the data plane will also be affected and the entire network will become abnormal.

A great number of attack packets directed to the CPU consume massive CPU resources, making the CPU highly loaded and thereby influencing device management and performance.

NFPP can effectively protect the system from these attacks. Facing attacks, NFPP maintains the proper running of various system services with a low CPU load, thereby ensuring the stability of the entire network.

22.2 Applications

Application	Description
Attack Rate Limiting	Due to various malicious attacks such as ARP attacks and IP scanning attacks in the network, the CPU cannot process normal protocol and management traffics, causing protocol flapping or management failure. The NFPP attack rate limiting function is used to limit the rate of attack traffic or isolate attack traffic to recover the network.
CentralizedBandwidth Allocation	If normal service traffics are too large, you need to classify and prioritize the traffics. When a large number of packets are directed to the CPU, the CPU will be highly loaded, thereby causing device management or device running failure. The centralized bandwidth distribution function is used to increase the priority of such traffics so that switches can run stably.

22.2.1 Attack Rate Limiting

Scenario

NFPP supports attack detection and rate limiting for various types of packets, including Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Dynamic Host Configuration Protocol (DHCP) packets. It also allows users to define packet matching characteristics and corresponding attack detection and rate limiting policies. The attack rate limiting

function takes effect based on types of packets. This section uses ARP packets as an example scenario to describe the application.

If an attacker floods ARP attack packets while CPU capability is insufficient, most of the CPU resources will be consumed for processing these ARP packets. If the rate of attacker's ARP packet rates exceeds the maximum ARP bandwidth specified in the CPU Protect Policy (CPP) of the switch, normal ARP packets may be dropped. As shown in Figure 22-1, normal hosts will fail to access the network, and the switch will fail to send ARP replies to other devices.

Figure 22-1

Deployment

- By default, the ARP attack detection and rate limiting function is enabled with corresponding policies configured. If the rate of an attacker's ARP packets exceeds the rate limit, the packets are discarded. If it exceeds the attack threshold, a monitoring user is generated and prompt information is exported.
- If the rate of an attacker's ARP packets exceeds the rate limit defined in CPP and affects normal ARP replies, you can enable attack isolation to discard ARP attack packets based on the hardware and recover the network.

i For details about CPP-related configurations, see the *Configuring CPU Protection*.

i To maximize the use of NFPP guard functions, modify the rate limits of various services in CPP based on the application environment or use the configurations recommended by the system. You can run the **show cpu-protect summary** command to display the configurations.

22.2.2 Centralized Bandwidth Allocation

Scenario

A switch classifies services defined in CPP into three types: Manage, Route, and Protocol. Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics with bandwidths exceeding the thresholds will be discarded. By such service classification, service packets are processed by orders of precedence.

As shown in Figure 22-2, the switch receives a large number of Telnet packets, OSPF packets, and ARP packets, causing CPU overload. In this case, the CPU cannot process all packets, and a large quantity of packets are backlogged in the queue, causing various problems such as frequent Telnet disconnection, OSPF protocol flapping, and ARP access failure on hosts.

Figure 22-2

Deployment

- By default, CPU centralized bandwidth allocation is enabled to assign an independent bandwidth and bandwidth ratio to each type of services. At the time, the CPU first processes Telnet packets to ensure uninterrupted connection of Telnet service, and then processes OSPF packets to maintain OSPF protocol stability, and finally processes ARP packets.
- If the preceding problems still occur in default configurations, you can accordingly adjust the bandwidths and bandwidth ratios of various types of services.

22.3 Features

Basic Concepts

↳ ARP Guard

In local area networks (LANs), IP addresses are mapped to MAC addresses through ARP, which has a significant role in safeguarding network security. ARP-based DoS attacks mean that a large number of unauthorized ARP packets are sent to the gateway through the network, causing the failure of the gateway to provide services for normal hosts. To prevent such attacks, limit the rate of ARP packets and identify and isolate the attack source.

↳ IP Guard

Many hacker attacks and network virus intrusions start from scanning active hosts in the network. Therefore, many scanning packets rapidly occupy the network bandwidth, causing network communication failure.

To solve this problem, Nodexon Layer-3 switches provide IP guard function to prevent hacker scanning and Blaster Worm viruses and reduce the CPU load. Currently, there are mainly two types of IP attacks:

Scanning destination IP address changes: As the greatest threat to the network, this type of attacks not only consumes network bandwidth and increases device load but also is a prelude of most hacker attacks.

Sending IP packets to non-existing destination IP addresses at high rates: This type of attacks is mainly designed for consuming the CPU load. For a Layer-3 device, if the destination IP address exists, packets are directly forwarded by the switching chip without occupying CPU resources. If the destination IP address does not exist, IP packets are sent to the CPU, which then sends ARP requests to query the MAC address corresponding to the destination IP address. If too many packets are sent to the CPU, CPU resources will be consumed. This type of attack is less destructive than the former one.

To prevent the latter type of attack, limit the rate of IP packets and find and isolate the attack source.

↘ ICMP Guard

ICMP is a common approach to diagnose network failures. After receiving an ICMP echo request from a host, the switch returns an ICMP echo reply. The preceding process requires the CPU to process the packets, thereby definitely consuming part of CPU resources. If an attacker sends a large number of ICMP echo requests to the destination device, massive CPU resources on the device will be consumed heavily, and the device may even fail to work properly. This type of attacks is called ICMP flood. To prevent this type of attacks, limit the rate of ICMP packets and find and isolate the attack source.

↘ DHCP Guard

DHCP is widely used in LANs to dynamically assign IP addresses. It is significant to network security. Currently, the most common DHCP attack, also called DHCP exhaustion attack, uses faked MAC addresses to broadcast DHCP requests. Various attack tools on the Internet can easily complete this type of attack. A network attacker can send sufficient DHCP requests to use up the address space provided by the DHCP server within a period. In this case, authorized hosts will fail to request DHCP IP addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCP packets and find and isolate the attack source.

↘ DHCPv6 Guard

DHCP version 6 (DHCPv6) is widely used in LANs to dynamically assign IPv6 addresses. Both DHCP version 4 (DHCPv4) and DHCPv6 have security problems. Attacks to DHCPv4 apply also to DHCPv6. A network attacker can send a large number of DHCPv6 requests to use up the address space provided by the DHCPv6 server within a period. In this case, authorized hosts will fail to request IPv6 addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCPv6 packets and find and isolate the attack source.

↘ ND Guard

Neighbor Discovery (ND) is mainly used in IPv6 networks to perform address resolution, router discovery, prefix discovery, and redirection. ND uses five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect. These packets are called ND packets.

↘ Self-Defined Guard

There are various types of network protocols, including routing protocols such as Open Shortest Path First (OSPF), Border Gateway Protocol (BGP), and Routing Information Protocol (RIP). Various devices need to exchange packets through different protocols. These packets must be sent to the CPU and processed by appropriate protocols. Once the network device runs a protocol, it is like opening a window for attackers. If an attacker sends a large number of protocol packets to a network device, massive CPU resources will be consumed on the device, and what's worse, the device may fail to work properly.

Since various protocols are being continuously developed, protocols in use vary with the user environments. Nodexon devices hereby provide self-defined guard. Users can customize and flexibly configure guard types to meet guard requirements in different user environments.

Overview

Feature	Description
Host-based Rate Limiting and Attack Identification	Limits the rate according to the host-based rate limit and identify host attacks in the network.
Port-based Rate Limiting and Attack Identification	Limits the rate according to the port-based rate limit and identify port attacks.
Monitoring Period	Monitors host attackers in a specified period.
Isolation Period	Uses hardware to isolate host attackers or port attackers in a specified period.
Trusted Hosts	Trusts a host by not monitoring it.
Centralized BandwidthAllocation	Classifies and prioritizes packets.

22.3.1 Host-based Rate Limiting and Attack Identification

Limit the rate of attack packets of hosts and identify the attacks.

Identify ARP scanning.

Identify IP scanning.

Working Principle

Hosts can be identified in two ways: based on the source IP address, VLAN ID, and port and based on the link-layer source MAC address, VLAN ID, and port. Each host has a rate limit and an attack threshold (also called alarm threshold). The rate limit must be lower than the attack threshold. If the attack packet rate exceeds the rate limit of a host, the host discards the packets beyond the rate limit. If the attack packet rate exceeds the attack threshold of a host, the host identifies and logs the host attacks, and sends traps.

ARP scanning attack may have occurred if ARP packets beyond the scanning threshold received in the configured period meet either of the following conditions:

- The link-layer source MAC address is fixed but the source IP address changes.
- The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes.

Among IP packets beyond the scanning threshold received in the configured period, if the source IP address remains the same while the destination IP address continuously changes, IP scanning attack may have occurred.

- i** When NFPP detects a specific type of attack packets under a service, it sends a trap to the administrator. If the attack traffic persists, NFPP will not resend the alarm until 60 seconds later.
- i** To prevent CPU resource consumption caused by frequent log printing, NFPP writes attack detection logs to the buffer, obtains them from the buffer at a specified rate, and prints them. NFPP does not limit the rate of traps.

Related Configuration

Use ARP guard as an example:

▾ Configuring the Global Host-based Rate Limit, Attack Threshold, and Scanning Threshold

In NFPP configuration mode:

Run the **arp-guard rate-limit** {**per-src-ip** | **per-src-mac**} *pps* command to configure rate limits of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard attack-threshold** {**per-src-ip** | **per-src-mac**} *pps* command to configure attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port.

Run the **arp-guard scan-threshold** *pkt-cnt* command to configure the ARP scanning threshold.

▾ Configuring Host-based Rate Limit and Attack Threshold, and Scanning Threshold on an Interface

In interface configuration mode:

Run the **nfpp arp-guard policy** {**per-src-ip** | **per-src-mac**} *rate-limit-pps attack-threshold-pps* command to configure rate limits and attack thresholds of hosts identified based on the source IP address, VLAN ID, and port and hosts identified based on the link-layer source MAC address, VLAN ID, and port on an interface.

Run the **nfpp arp-guard scan-threshold** *pkt-cnt* command to configure the scanning threshold on an interface.

 Only ARP guard and IP guard support anti-scanning at present.

22.3.2 Port-based Rate Limiting and Attack Identification

Working Principle

Each port has a rate limit and an attack threshold. The rate limit must be lower than the attack threshold. If the packet rate exceeds the rate limit on a port, the port discards the packets. If the packet rate exceeds the attack threshold on a port, the port logs the attacks and sends traps.

Related Configuration

Use ARP guard as an example:

▾ Configuring the Global Port-based Rate Limit and Attack Threshold

In NFPP configuration mode:

Run the **arp-guard rate-limit per-port** *pps* command to configure the rate limit of a port.

Run the **arp-guard attack-threshold per-port** *pps* command to configure the attack threshold of a port.

▾ Configuring Port-based Rate Limit and Attack Threshold on an Interface

In interface configuration mode:

Run the **nfpp arp-guard policy per-port** *rate-limit-pps attack-threshold-pps* command to configure the rate limit and attack threshold of a port.

22.3.3 Monitoring Period

Working Principle

The monitoring user provides information about attackers in the current system. If the isolation period is 0 (that is, not isolated), the guard module automatically performs software monitoring on attackers in the configured monitoring period. If the isolation period is set to a non-zero value, the guard module automatically isolates the hosts monitored by software.

During software monitoring, if the isolation period is set to a non-zero value, the guard module automatically isolates the attacker and sets the timeout period as the isolation period.

The monitoring period is valid only when the isolation period is 0.

Related Configuration

Use ARP guard as an example:

↘ [Configuring the Global Monitoring Period](#)

In NFPP configuration mode:

Run the **arp-guard monitor-period** *seconds* command to configure the monitoring period.

22.3.4 Isolation Period

Working Principle

Isolation is performed by the guard policies after attacks are detected. Isolation is implemented using the filter of the hardware to ensure that these attacks will not be sent to the CPU, thereby ensuring proper running of the device.

Hardware isolation supports two modes: host-based and port-based isolation. At present, only ARP guard supports port-based hardware isolation.

A policy is configured in the hardware to isolate attackers. However, hardware resources are limited. When hardware resources are used up, the system prints logs to notify the administrator.

Related Configuration

Use ARP guard as an example:

↘ [Configuring the Global Isolation Period](#)

In NFPP configuration mode:

Run the **arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

↘ [Configuring the Isolation Period on an Interface](#)

In interface configuration mode:

Run the **nfpp arp-guard isolate-period** [*seconds* | **permanent**] command to configure the isolation period. If the isolation period is set to 0, isolation is disabled. If it is set to a non-zero value, the value indicates the isolation period. If it is set to **permanent**, ARP attacks are permanently isolated.

↳ Enabling Isolate Forwarding

In NFPP configuration mode:

Run the **arp-guard isolate-forwarding enable** command to enable isolate forwarding.

↳ Enabling Port-based Ratelimit Forwarding

In NFPP configuration mode:

Run the **arp-guard ratelimit-forwarding enable** command to enable port-based ratelimit forwarding.

i At present, only ARP guard supports the configuration of isolate forwarding and ratelimit forwarding.

22.3.5 Trusted Hosts

Working Principle

If you do not want to monitor a host, you can run related commands to trust the host. This trusted host will be allowed to send packets to the CPU.

Related Configuration

Use IP anti-scanning as an example:

↳ Configuring Trusted Hosts

In NFPP configuration mode:

Run the **ip-guard trusted-host** *ip mask* command to trust a host.

Run the **trusted-host** {*mac mac_mask* | *ip mask* | *IPv6/prefixlen*} command to trust a host for a self-defined guard.

22.3.6 Centralized Bandwidth Allocation

Working Principle

Services defined in CPP are classified into three types: Manage, Route, and Protocol. (For details, see the following table.) Each type of service has an independent bandwidth. Different types of services cannot share their bandwidths. Traffics exceeding the bandwidth thresholds are discarded. By such service classification, service packets are processed by orders of precedence.

NFPP allows the administrator to flexibly assign bandwidth for three types of packets based on the actual network environment so that Protocol and Manage packets can be first processed. Prior processing of Protocol packets ensures proper running of protocols, and prior processing of Manage packets ensures proper management for the administrator, thereby ensuring proper running of important device functions and improving the guard capability of the device.

After classified rate limiting, all types of packets are centralized in a queue. When one type of service is processed inefficiently, packets of this service will be backlogged in the queue and may finally use up resources of the queue. NFPP allows the administrator to configure the percentages of these three types of packets in the queue. When the queue length occupied by one type of packets exceeds the value of the total queue length multiplied by the percentage of this packet type, the excessive packets will be discarded. This efficiently prevents one type of packets from exclusively occupying queue resources.

Packet Type	Service Type Defined in CPP
Protocol	tp-guard, dot1x, rldp, rerp, slow-packet, bpdu, isis dhcps, gvrp, ripng, dvmrp, igmp, mpls, ospf, pim, pimv6, rip, vrrp, ospf3, dhcp-relay-s, dhcp-relay-c, option82, tunnel-bpdu, tunnel-gvrp
Route	unknown-ipmc, unknown-ipmcv6, ttl1, ttl0, udp-helper, ip4-packet-other, ip6-packet-other, non-ip-packet-other, arp
Manage	ip4-packet-local, ip6-packet-local

 For the definitions of service types, see the Configuring CPU Protection.

Related Configuration

▾ Configuring the Maximum Bandwidth of Specified Packets

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol|route} pps pps_value** command to configure the maximum bandwidth of specified packets.

▾ Configuring the Maximum Percentage of Specified Packets in the Queue

In global configuration mode:

Run the **cpu-protect sub-interface { manage | protocol | route} percent percent_value** command to configure the maximum percentage of specified packets in the queue.

22.4 Configuration

Configuration	Description and Command	
Configuring ARP Guard	arp-guard enable	Enables ARP guard globally.
	arp-guard isolate-period	Configures the global ARP-guard isolation period.
	arp-guard isolate-forwarding enable	Enables ARP-guard isolate forwarding.
	arp-guard ratelimit-forwarding enable	Enables APR-guard ratelimit forwarding.
	arp-guard monitor-period	Configures the global ARP-guard monitoring period.
	arp-guard monitored-host-limit	Configures the maximum number of ARP-guard monitored hosts.
	arp-guard rate-limit	Configures the global ARP-guard rate limit.

Configuration	Description and Command	
	arp-guard attack-threshold	Configures the global ARP-guard attack threshold.
	arp-guard scan-threshold	Configures the global ARP-guard scanning threshold.
	nfpp arp-guard enable	Enables ARP guard on an interface.
	nfpp arp-guard policy	Configures the APR-guard rate limit and attack threshold on an interface.
	nfpp arp-guard scan-threshold	Configures the APR-guard scanning threshold on an interface.
	nfpp arp-guard isolate-period	Configures the APR-guard isolation period on an interface.
Configuring IP Guard	ip-guard enable	Enables IP guard globally.
	ip-guard isolate-period	Configures the global IP-guard isolation period.
	ip-guard monitor-period	Configures the global IP-guard monitoring period.
	ip-guard monitored-host-limit	Configures the maximum number of IP-guard monitored hosts.
	ip-guard rate-limit	Configures the global IP-guard rate limit.
	ip-guard attack-threshold	Configures the global IP-guard attack threshold.
	ip-guard scan-threshold	Configures the global IP-guard scanning threshold.
	ip-guard trusted-host	Configures IP-guard trusted hosts.
	nfpp ip-guard enable	Enables IP guard on an interface.
	nfpp ip-guard policy	Configures the IP-guard rate limit and attack threshold on an interface.
	nfpp ip-guard scan-threshold	Configures the IP-guard scanning threshold on an interface.
nfpp ip-guard isolate-period	Configures the IP-guard isolation period on an interface.	
Configuring ICMP Guard	icmp-guard enable	Enables ICMP guard globally.
	icmp-guard isolate-period	Configures the global ICMP-guard isolation period.
	icmp-guard monitor-period	Configures the global ICMP-guard monitoring period.
	icmp-guard monitored-host-limit	Configures the maximum number of ICMP-guard monitored hosts.
	icmp-guard rate-limit	Configures the global ICMP-guard rate limit.
	icmp-guard attack-threshold	Configures the global ICMP-guard attack threshold.

Configuration	Description and Command	
	icmp-guard trusted-host	Configures ICMP-guard trusted hosts.
	nfpp icmp-guard enable	Enables ICMP guard on an interface.
	nfpp icmp-guard policy	Configures the ICMP-guard rate limit and attack threshold on an interface.
	nfpp icmp-guard isolate-period	Configures the ICMP-guard isolation period on an interface.
Configuring DHCP Guard	dhcp-guard enable	Enables DHCP guard globally.
	dhcp-guard isolate-period	Configures the global DHCP-guard isolation period.
	dhcp-guard monitor-period	Configures the global DHCP-guard monitoring period.
	dhcp-guard monitored-host-limit	Configures the maximum number of DHCP-guard monitored hosts.
	dhcp-guard rate-limit	Configures the global DHCP-guard rate limit.
	dhcp-guard attack-threshold	Configures the global DHCP-guard attack threshold.
	nfpp dhcp-guard enable	Enables DHCP guard on an interface.
	nfpp dhcp-guard policy	Configures the DHCP-guard rate limit and attack threshold on an interface.
	nfpp dhcp-guard isolate-period	Configures the DHCP-guard isolation period on an interface.
Configuring DHCPv6 Guard	dhcpv6-guard enable	Enables DHCPv6 guard globally.
	dhcpv6-guard isolate-period	Configures the global DHCPv6-guard isolation period.
	dhcpv6-guard monitor-period	Configures the global DHCPv6-guard monitoring period.
	dhcpv6-guard monitored-host-limit	Configures the maximum number of DHCPv6-guard monitored hosts.
	dhcpv6-guard rate-limit	Configures the global DHCPv6-guard rate limit.
	dhcpv6-guard attack-threshold { per-src-mac per-port} pps	Configures the global DHCPv6-guard attack threshold.
	nfpp dhcpv6-guard enable	Enables DHCPv6 guard on an interface.
	nfpp dhcpv6-guard policy	Configures the DHCPv6-guard rate limit and attack threshold on an interface.
	nfpp dhcpv6-guard isolate-period	Configures the DHCPv6-guard isolation period on an interface.
Configuring ND Guard	nd-guard enable	Enables ND guard globally.
	nd-guard ratelimit-forwarding enable	Enables ND-guard ratelimit forwarding.
	nd-guard rate-limit per-port	Configures the global ND-guard rate limit.

Configuration	Description and Command	
	nd-guard attack-threshold per-port	Configures the global ND-guard attack threshold.
	nfpp nd-guard enable	Enables ND guard on an interface.
	nfpp nd-guard policy per-port	Configures the ND-guard rate limit and attack threshold on an interface.
Configuring a Self-Defined Guard	define	Configures the name of a self-defined guard.
	match	Configures match fields of a self-defined guard.
	global-policy	Configures the global rate limit and attack threshold of a self-defined guard.
	isolate-period	Configures the global isolation period of a self-defined guard.
	monitor-period	Configures the global monitoring period of a self-defined guard.
	monitored-host-limit	Configures the maximum number of monitored hosts of a self-defined guard.
	trusted-host	Configures trusted hosts of a self-defined guard.
	define name enable	Enables a self-defined guard globally.
	nfpp define name enable	Enables a self-defined guard on an interface.
Configuring NFPP Logging	nfpp define	Configures the rate limit and attack threshold of a self-defined guard on an interface.
	log-buffer entries	Configures the log buffer size.
	log-buffer logs	Configures the log buffer rate.
	logging vlan	Configures VLAN-based logging filtering.
	logging interface	Configures interface-based logging filtering.
	logging enable	Enables log printing.

22.4.1 Configuring ARP Guard

[Configuration Effect](#)

- ARP attacks are identified based on hosts or ports. Host-based ARP attack identification supports two modes: identification based on the source IP address, VLAN ID, and port and identification based on the link-layer source MAC address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ARP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ARP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- ARP guard can also detect ARP scanning attacks. ARP scanning attacks indicate that the link-layer source MAC address is fixed but the source IP address changes, or that the link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes. Due to the possibility of false positive, hosts possibly performing ARP scanning are not isolated and are provided for the administrator's reference only.

- Configure ARP-guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- ARP guard prevents only ARP DoS attacks to the switch, but not ARP spoofing or ARP attacks in the network.
- For trusted ports configured for Dynamic ARP Inspection (DAI), ARP guard does not take effect, preventing false positive of ARP traffic over the trusted ports. For details about DAI trusted ports, see the Configuring Dynamic ARP Inspection.

Configuration Steps

▾ Enabling ARP Guard

- (Mandatory) ARP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ARP guard is disabled, the system automatically clears monitored hosts, scanned hosts, and isolated entries on ports.

▾ Configuring the ARP-Guard Isolation Period

- (Optional) ARP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Enabling ARP-Guard Isolate Forwarding

- (Optional) ARP-guard isolate forwarding is enabled by default.
- To make isolation valid only at the management plane instead of the forwarding plane, you can enable this function.
- This function can be enabled in NFPP configuration mode.

▾ Enabling ARP-Guard Ratelimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

▾ Configuring the ARP-Guard Monitoring Period

- (Mandatory) The default ARP-guard monitoring period is 600 seconds.
- If the ARP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ **Configuring the Maximum Number of ARP-Guard Monitored Hosts**

- (Mandatory) The maximum number of ARP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ARP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of ARP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ARP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ **Configuring the ARP-Guard Attack Threshold**

- Mandatory.
- To achieve the best ARP-guard effect, you are advised to configure the host-based rate limit and attack threshold based on the following order: Source IP address-based rate limit < Source IP address-based attack threshold < Source MAC address-based rate limit < Source MAC address-based attack threshold.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ARP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over source IP address-based rate limiting while the latter takes priority over port-based rate limiting.

▾ **Configuring the ARP-Guard Scanning Threshold**

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- The ARP scanning table stores only the latest 256 records. When the ARP scanning table is full, the latest record will overwrite the earliest record.

- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet either of the following conditions:
 - The link-layer source MAC address is fixed but the source IP address changes.
 - The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes, and the change times exceed the scanning threshold.

Verification

When a host in the network sends ARP attack packets to a switch configured with ARP guard, check whether these packets can be sent to the CPU.

- If the packets exceed the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ Enabling ARP Guard Globally

Command	arp-guard enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global ARP-Guard Isolation Period

Command	arp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP-Guard Isolate Forwarding

Command	arp-guard isolate-forwarding enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP-Guard Ratelimit Forwarding

Command	arp-guard ratelimit-forwarding enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global ARP-Guard Monitoring Period

Command	arp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Maximum Number of ARP-Guard Monitored Hosts

Command	arp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global ARP-Guard Rate Limit

Command	arp-guard rate-limit { per-src-ip per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-ip : Limits the rate of each source IP address. per-src-mac : Limits the rate of each source MAC address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

📌 Configuring the Global ARP-Guard Attack Threshold

Command	arp-guard attack-threshold { per-src-ip per-src-mac per-port } <i>pps</i>
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-src-mac : Configures the attack threshold of each source MAC address. per-port : Configures the attack threshold of each port. <i>pps</i> : Indicates the attack threshold, ranging from 1 to 19,999. The unit is packets per second (pps).
Command	NFPP configuration mode

Mode	
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

↘ Configuring the Global ARP-Guard Scanning Threshold

Command	arp-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling ARP Guard on an Interface

Command	nfpp arp-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	ARP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the ARP-Guard Isolation Period on an Interface

Command	nfpp arp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the ARP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp arp-guard policy { per-src-ip per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-src-mac : Configures the rate limit and attack threshold of each source MAC address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

➤ **Configuring the ARP-Guard Scanning Threshold on an Interface**

Command	nfpp arp-guard scan-threshold <i>pkt-cnt</i>
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

➤ **CPU Protection Based on ARP Guard**

Scenario	<ul style="list-style-type: none"> ARP host attacks exist in the system, and some hosts fail to properly establish ARP connection. ARP scanning exists in the system, causing a very high CPU utilization rate.
Configuration Steps	<ul style="list-style-type: none"> Set the host-based attack threshold to 5 pps. Set the ARP scanning threshold to 10 pps. Set the isolation period to 180 pps.
	<pre>Nodexon# configure terminal Nodexon(config)# nfpp Nodexon (config-nfpp)#arp-guard rate-limit per-src-mac 5 Nodexon (config-nfpp)#arp-guard attack-threshold per-src-mac 10 Nodexon (config-nfpp)#arp-guard isolate-period 180</pre>

22.4.2 Configuring IP Guard

Configuration Effect

- IP attacks are identified based on hosts or physical interfaces. In host-based IP attack identification, IP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the IP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the IP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- IP guard can also detect IP scanning attacks. IP anti-scanning applies to IP packet attacks as follows: the destination IP address continuously changes but the source IP address remains the same, and the destination IP address is not the IP address of the local device.
- Configure IP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.
- IP anti-scanning applies to IP packet attacks where the destination IP address is not the local IP address. The CPP limits the rate of IP packets where the destination IP address is the local IP address.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

📌 Enabling IP Guard

- (Mandatory) IP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.

- If IP guard is disabled, the system automatically clears monitored hosts.

▾ **Configuring the IP-Guard Isolation Period**

- (Optional) IP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ **Configuring the IP-Guard Monitoring Period**

- (Mandatory) The default IP-guard monitoring period is 600 seconds.
- If the IP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ **Configuring the Maximum Number of IP-Guard Monitored Hosts**

- (Mandatory) The maximum number of IP-guard monitored hosts is 20,000 by default.
- Set the maximum number of IP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of IP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20,000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_IP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ **Configuring the IP-Guard Attack Threshold**

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_IP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

↘ **Configuring the IP-Guard Scanning Threshold**

- Mandatory.
- The scanning threshold can be configured in NFPP configuration mode or interface configuration mode.
- ARP scanning attack may have occurred if ARP packets received within 10 seconds meet the following conditions:
 - The source IP address remains the same.
 - The destination IP address continuously changes and is not the local IP address, and the change times exceed the scanning threshold.

↘ **Configuring IP-Guard Trusted Hosts**

- (Optional) No IP-guard trusted host is configured by default.
- For IP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends IP attack packets to a switch configured with IP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from untrusted hosts exceeds the attack threshold or scanning threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↘ **Enabling IP Guard Globally**

Command	ip-guard enable
Parameter	N/A
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Isolation Period

Command	ip-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Monitoring Period

Command	ip-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↘ Configuring the Maximum Number of IP-Guard Monitored Hosts

Command	ip-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global IP-Guard Rate Limit

Command	ip-guard rate-limit { per-src-ip per-port } <i>pps</i>
Parameter Description	per-src-ip : Limits the rate of each source IP address. per-port : Limits the rate of each port. <i>pps</i> : Indicates the rate limit, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode

Usage Guide	N/A
--------------------	-----

↘ Configuring the Global IP-Guard Attack Threshold

Command	ip-guard attack-threshold {per-src-ip per-port} pps
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. pps: Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

↘ Configuring the Global IP-Guard Scanning Threshold

Command	ip-guard scan-threshold pkt-cnt
Parameter Description	pkt-cnt: Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring IP-Guard Trusted Hosts

Command	ip-guard trusted-host ip mask
Parameter Description	ip : Indicates the IP address. mask : Indicates the mask of an IP address. all : Used with no to delete all trusted hosts.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send IP packets to the CPU, without any rate limiting or alarm reporting.

↘ Enabling IP Guard on an Interface

Command	nfpp ip-guard enable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	IP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the IP-Guard Isolation Period on an Interface

Command	nfpp ip-guard isolate-period [seconds permanent]
----------------	---

Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

📌 Configuring the IP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp ip-guard policy {per-src-ip per-port} rate-limit-pps attack-threshold-pps
Parameter Description	per-src-ip : Configures the attack threshold of each source IP address. per-port : Configures the attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

📌 Configuring the IP-Guard Scanning Threshold on an Interface

Command	nfpp ip-guard scan-threshold pkt-cnt
Parameter Description	<i>pkt-cnt</i> : Indicates the scanning threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	N/A

22.4.3 Configuring ICMP Guard

Configuration Effect

- ICMP attacks are identified based on hosts or ports. In host-based attack identification, ICMP attacks are identified based on the source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the ICMP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ICMP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- Configure ICMP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

▾ Enabling ICMP Guard

- (Mandatory) ICMP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If ICMP guard is disabled, the system automatically clears monitored hosts.

▾ Configuring the ICMP-Guard Isolation Period

- (Optional) ICMP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the ICMP-Guard Monitoring Period

- (Mandatory) The default ICMP-guard monitoring period is 600 seconds.
- If the ICMP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ Configuring the Maximum Number of ICMP-Guard Monitored Hosts

- (Mandatory) The maximum number of ICMP-guard monitored hosts is 20,000 by default.
- Set the maximum number of ICMP-guard monitored hosts reasonably. As the number of actually monitored hosts increases, more CPU resources are used.
- The maximum number of ICMP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ Configuring the ICMP-Guard Attack Threshold

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_ICMP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes priority over port-based rate limiting.

▾ Configuring ICMP-Guard Trusted Hosts

- (Optional) No ICMP-guard trusted host is configured by default.
- For ICMP guard, you can only configure a maximum of 500 IP addresses not to be monitored.
- Trusted hosts can be configured in NFPP configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ICMP attack packets to a switch configured with ICMP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

↳ Enabling ICMP Guard Globally

Command	icmp-guard enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

↳ Configuring the Global ICMP-Guard Isolation Period

Command	icmp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into two types: global isolation period and port-based isolation period (local isolation period). For a port, if the port-based isolation period is not configured, the global isolation period is used; otherwise, the port-based isolation period is used.

↳ Configuring the Global ICMP-Guard Monitoring Period

Command	icmp-guard monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

↳ Configuring the Maximum Number of ICMP-Guard Monitored Hosts

Command	icmp-guard monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The

	<p>value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.</p> <p>If the table of monitored hosts is full, the system prints the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.</p>
--	--

↘ Configuring the Global ICMP-Guard Rate Limit

Command	icmp-guard rate-limit {per-src-ip per-port} pps
Parameter Description	<p>per-src-ip: Limits the rate of each source IP address.</p> <p>per-port: Limits the rate of each port.</p> <p><i>pps:</i> Indicates the rate limit, ranging from 1 to 19,999.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global ICMP-Guard Attack Threshold

Command	icmp-guard attack-threshold {per-src-ip per-port} pps
Parameter Description	<p>per-src-ip: Configures the attack threshold of each source IP address.</p> <p>per-port: Configures the attack threshold of each port.</p> <p><i>pps:</i> Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring ICMP-Guard Trusted Hosts

Command	icmp-guard trusted-host ip mask
Parameter Description	<p><i>ip:</i> Indicates the IP address.</p> <p><i>mask:</i> Indicates the mask of an IP address.</p> <p>all: Used with no to delete all trusted hosts.</p>
Command Mode	NFPP configuration mode
Usage Guide	<p>If you do not want to monitor a host, you can run this command to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored.</p> <p>You can configure a maximum of 500 trusted hosts.</p>

↘ Enabling ICMP Guard on an Interface

Command	nfpp icmp-guard enable
Parameter Description	N/A
Command	Interface configuration mode

Mode	
Usage Guide	ICMP guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the ICMP-Guard Isolation Period on an Interface

Command	nfpp icmp-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the ICMP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp icmp-guard policy { per-src-ip per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

22.4.4 Configuring DHCP Guard

Configuration Effect

- DHCP attacks are identified based on hosts or ports. In host-based attack identification, DHCP attacks are identified based on the link-layer source IP address, VLAN ID, and port. Each type of attack identification has a rate limit and an attack threshold. If the DHCP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCP packet rate exceeds the attack threshold, the system prints alarm information and sends traps. In host-based attack identification, the system also isolates the attack source.
- Configure DHCP guard isolation to assign hardware-isolated entries against host attacks so that attack packets are neither sent to the CPU nor forwarded.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.

- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- For trusted ports configured for DHCP snooping, DHCP guard does not take effect, preventing false positive of DHCP traffic on the trusted ports. For details about trusted ports of DHCP snooping, see "Configuring Basic Functions of DHCP Snooping" in the Configuring DHCP Snooping.

Configuration Steps

▾ Enabling DHCP Guard

- (Mandatory) DHCP guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.
- If DHCP guard is disabled, the system automatically clears monitored hosts.

▾ Configuring the DHCP-Guard Isolation Period

- (Optional) DHCP-guard isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in NFPP configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ Configuring the DHCP-Guard Monitoring Period

- (Mandatory) DHCP-guard monitoring is enabled by default.
- If the DHCP-guard isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in NFPP configuration mode.

▾ Configuring the Maximum Number of DHCP-Guard Monitored Hosts

- (Mandatory) The maximum number of DHCP-guard monitored hosts is 20,000 by default.
- Set the maximum number of DHCP-guard monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of DHCP-guard monitored hosts can be configured in NFPP configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.

▾ Configuring the DHCP-Guard Attack Threshold

- Mandatory.
- The attack threshold can be configured in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DHCP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes priority over port-based rate limiting.

Verification

When a host in the network sends DHCP attack packets to a switch configured with DHCP guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

↘ Configuring the Maximum Number of DHCPv6-Guard Monitored Hosts

Command	<code>dhcpv6-guard monitored-host-limit number</code>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	NFPP configuration mode
Usage Guide	<p>If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.</p> <p>If the table of monitored hosts is full, the system prints the log "%NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 20000 monitored hosts." to notify the administrator.</p>

↘ Configuring the Global DHCPv6-Guard Rate Limit

Command	<code>dhcpv6-guardrate-limit { per-src-mac per-port} pps</code>
Parameter Description	<p>per-src-mac: Limits the rate of each source MAC address.</p> <p>per-port: Limits the rate of each port.</p> <p><i>pps</i>: Indicates the rate limit, ranging from 1 to 19,999.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Configuring the Global DHCPv6-Guard Attack Threshold

Command	<code>dhcpv6-guard attack-threshold { per-src-mac per-port} pps</code>
Parameter Description	<p>per-src-mac: Configures the attack threshold of each source MAC address.</p> <p>per-port: Configures the attack threshold of each port.</p> <p><i>pps</i>: Indicates the attack threshold, ranging from 1 to 19,999. The unit is pps.</p>
Command Mode	NFPP configuration mode
Usage Guide	N/A

↘ Enabling DHCPv6 Guard on an Interface

Command	<code>nfpp dhcpv6-guard enable</code>
----------------	---------------------------------------

Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 guard configured in interface configuration mode takes priority over that configured in NFPP configuration mode.

↘ Configuring the DHCPv6-Guard Isolation Period on an Interface

Command	nfpp dhcpv6-guard isolate-period [<i>seconds</i> permanent]
Parameter Description	<i>seconds</i> : Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation. permanent : Indicates permanent isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

↘ Configuring the DHCP-Guard Rate Limit and Attack Threshold on an Interface

Command	nfpp dhcpv6-guard policy { per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

↘ CPU Protection Based on DHCPv6 Guard

Scenario	<ul style="list-style-type: none"> DHCPv6 host attacks exist in the system, and DHCPv6 neighbor discovery fails on some hosts.
Configuration Steps	<ul style="list-style-type: none"> Configure the host-based attack threshold. Set the isolation period to a non-zero value.
	<pre>Nodexon# configure terminal Nodexon(config)# nfpp Nodexon (config-nfpp)#dhcpv6-guard rate-limit per-src-mac 8 Nodexon (config-nfpp)#dhcpv6-guard attack-threshold per-src-mac 16 Nodexon (config-nfpp)#dhcpv6-guard isolate-period 180</pre>
Verification	<ul style="list-style-type: none"> Run the show nfpp dhcpv6-guard summary command to display the configuration.
	(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)

<pre> Interface Status Isolate-period Rate-limit Attack-threshold Global Disable 180 -/8/150 -/16/300 Maximum count of monitored hosts: 1000 Monitor period: 600s </pre>
<ul style="list-style-type: none"> ● Run the show nfpp dhcpv6-guard hosts command to display the monitored hosts.
<pre> If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface MAC address remain-time(s) ----- - *1 Gi0/5 001a.a9c2.4609 160 Total: 1 host </pre>

Common Errors

N/A

22.4.6 Configuring ND Guard

Configuration Effect

- AR ND guard classifies ND packets into three types based on their purposes: 1. NS and NA; 2. RS; 3. RA and Redirect. Type 1 packets are used for address resolution. Type 2 packets are used by hosts to discover the gateway. Type 3 packets are related to routing: RAs are used to advertise the gateway and prefix while Redirect packets are used to advertise a better next hop.
- At present, only port-based ND packet attack identification is supported. You can configure the rate limits and attack thresholds for these three types of packets respectively. If the ND packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ND packet rate exceeds the attack threshold, the system prints logs and sends traps.

Notes

- For a command that is configured both in NFPP configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in NFPP configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.

Configuration Steps

📌 **Enabling ND Guard**

- (Mandatory) ND guard is enabled by default.
- This function can be enabled in NFPP configuration mode or interface configuration mode.

↘ Enabling ND-Guard Ratelimit Forwarding

- (Optional) This function is enabled by default.
- If the port-based isolation entry takes effect, you can enable this function to pass some of the packets while not discarding all of them.
- This function can be enabled in NFPP configuration mode.

↘ Configuring the ND-Guard Attack Threshold

- Mandatory.
- The ND-guard attack threshold can be enabled in NFPP configuration mode or interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If memories cannot assigned to detected attackers, the system prints the log "%NFPP_ND_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.

Verification

When a host in the network sends ND attack packets to a switch configured with ND guard, check whether these packets can be sent to the CPU.

- If the parameter of the packets exceeds the attack threshold, an attack log is displayed.

Common Errors

N/A

22.4.7 Configuring a Self-Defined Guard

Configuration Effect

- Configure a self-defined guard to resolve network attack problems in special scenarios.

Notes

- For a command that is configured both in self-defined guard configuration mode and interface configuration mode, the configuration in interface configuration mode takes priority over that configured in self-defined guard configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy hardware entries of the security module.
- A self-defined guard takes priority over basic guards. When configuring the match fields of self-defined guards, see the Configuration Guide.

Configuration Steps

📄 Configuring the Guard Name

- (Mandatory) Configure the name of a self-defined guard to create the self-defined guard.
- The guard name must be unique, and the match fields and values c must be different from those of ARP, ICMP, DHCP, IP, and DHCPv6 guards. If the parameters you want to configure already exist, a message is displayed to indicate the configuration failure.

📄 Configuring the Match Fields

- Mandatory.
- Self-defined packets are classified based on the following fields: etype (Ethernet link-layer type), smac (source MAC address), dmac (destination MAC address), protocol (IPv4/IPv6 protocol number), sip (source IPv4/IPv6 address), dip (destination IPv4/IPv6 address), sport (source transport-layer port), and dport (destination transport-layer port).
- **protocol** is valid only when the value of **etype** is **ipv4** or **ipv6**. **src-ip** and **dst-ip** are valid only when the value of **etype** is **ipv4**. **src-ipv6** and **dst-ipv6** are valid only when the value of **etype** is **ipv6**. **src-port** and **dst-port** are valid only when the value of **protocol** is **tcp** or **udp**.
- If the **match** fields and values of a self-defined guard are totally the same as those of an existing guard, the system prints the log "%ERROR: the match type and value are the same with define name (name of an existing guard)." to notify the administrator of the configuration failure.
- If **protocol** is configured but **etype** is IPv4 or IPv6 in the **match** policy, the system prints the log "%ERROR: protocol is valid only when etype is IPv4(0x0800) or IPv6(0x86dd)."
- If **src-ip** and **dst-ip** are configured but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: IP address is valid only when etype is IPv4(0x0800)."
- If **src-ipv6** and **dst-ipv6** are configured but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: IPv6 address is valid only when etype is IPv6(0x86dd)."
- If **src-port** and **dst-port** are configured but **protocol** is not TCP or UDP in the **match** policy, the system prints the log "%ERROR: Port is valid only when protocol is TCP(6) or UDP(17)."
- The following table lists guard policies corresponding to some common network protocols. The rate limits and attack thresholds listed below can meet the requirements in most network scenarios and are for reference only. You can configure valid rate limits and attack thresholds based on actual scenarios.

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
RIP	etype 0x0800 protocol 17 dst-port 520	rate-limit 100 attatch-threshold 150	Not applicable to this policy	rate-limit 300 attatch-threshold 500
RIPng	etype 0x86dd protocol 17 dst-port 521	rate-limit 100 attatch-threshold 150	Not applicable to this policy	rate-limit 300 attatch-threshold 500
BGP	etype 0x0800 protocol 6 dst-port 179	rate-limit 1000 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
BPDU	dst-mac 0180.c200.0000	Not applicable to this policy	rate-limit 20 attatch-threshold 40	rate-limit 100 attatch-threshold 100
RERP	dst-mac 01d0.f800.0001	Not applicable to this policy	rate-limit 20 attatch-threshold 40	rate-limit 100 attatch-threshold 100
REUP	dst-mac 01d0.f800.0007	Not applicable to this policy	rate-limit 20 attatch-threshold 40	rate-limit 100 attatch-threshold 100

Protocol	match	policy per-src-ip	policy per-src-mac	policy per-port
BGP	etype 0x0800 protocol 6 dst-port 179	Not applicable to this policy	Not applicable to this policy	Not applicable to this policy
OSPFv2	etype 0x0800 protocol 89	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
OSPFv3	etype 0x86dd protocol 89	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
VRRP	etype 0x0800 protocol 112	rate-limit 64 attatch-threshold 100	Not applicable to this policy	rate-limit 1024 attatch-threshold 1024
IPv6 VRRP	etype 0x86dd protocol 112	rate-limit 64 attatch-threshold 100	Not applicable to this policy	rate-limit 1024 attatch-threshold 1024
SNMP	etype 0x0800 protocol 17 dst-port 161	rate-limit 1000 attatch-threshold 1200	Not applicable to this policy	rate-limit 2000 attatch-threshold 3000
RSVP	etype 0x0800 protocol 46	rate-limit 800 attatch-threshold 1200	Not applicable to this policy	rate-limit 1200 attatch-threshold 1500
LDP (UDP hello)	etype 0x0800 protocol 17 dst-port 646	rate-limit 10 attatch-threshold 15	Not applicable to this policy	rate-limit 100 attatch-threshold 150

- To contain as many existing protocol types as possible and facilitate expansion of new protocol types, self-defined guards allow hosts to freely combine type fields of packets. If the configuration is inappropriate, the network may become abnormal. Therefore, the network administrator needs to have a good knowledge of network protocols. As a reference, the following table lists valid configurations of currently known protocols for common self-defined guard policies. For other protocols not listed in the table, configure them with caution.

📌 Configuring the Global Rate Limit and Attack Threshold

- (Mandatory) If these parameters are not configured, the self-defined guard cannot be enabled.
- You must configure one of the per-src-ip, per-src-mac, and per-port fields. Otherwise, the policy cannot take effect.
- per-src-ip is valid only when etype is IPv4 or IPv6.
- The rate limit configured based on the source MAC address, VLAN ID, and port takes priority over that configured based on the source IP address, VLAN ID, and port.
- The port-based host identification policy of a self-defined guard must be consistent with the global port-based host identification policy.
- If the **per-src-ip** policy is not configured globally but configured for a port, the system prints the log "%ERROR: name (name of a self-defined guard) has not per-src-ip policy." to notify the administrator of the configuration failure.
- If the **per-src-mac** policy is not configured globally but configured for a port, the system prints the log "%ERROR: name (name of a self-defined guard) has not per-src-mac policy." to notify the administrator of the configuration failure.

- If the memory cannot be allocated to detected attackers, the system prints the log "%NFPP_DEFINE_GUARD-4-NO_MEMORY: Failed to allocate memory." to notify the administrator.
- If the configured rate limit is greater than the attack threshold, the system prints the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is less than the rate limit, the system prints the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.

▾ **Configuring the Global Isolation Period**

- (Optional) Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit defined in CPP, you can configure the isolation period to discard packets and therefore to save bandwidth resources.
- The isolation period can be configured in self-defined guard configuration mode or interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ **Configuring the Global Monitoring Period**

- (Mandatory) The default monitoring period is 600 seconds.
- If the isolation period is configured, it is directly used as the monitoring period, and the configured monitoring period will lose effect.
- The monitoring period can be configured in self-defined guard configuration mode.
- If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs hardware isolation against monitored attackers and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored.

▾ **Configuring the Maximum Number of Monitored Hosts**

- (Mandatory) The maximum number of monitored hosts is 20,000 by default.
- Set the maximum number of monitored hosts reasonably. As the number of monitored hosts increases, more CPU resources are used.
- The maximum number of monitored hosts can be configured in self-defined guard configuration mode.
- If the number of monitored hosts reaches 20,000 (default value) and the administrator sets the maximum number lower than 20,000, the system does not delete monitored hosts but prints the log "%ERROR: The value that you configured is smaller than current monitored hosts 20000, please clear a part of monitored hosts." This information notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system prints the log "% NFPP_DEFINE-4-SESSION_LIMIT: Attempt to exceed limit of name's 20000 monitored hosts." to notify the administrator.

▾ **Configuring Trusted Hosts**

- (Optional) No trusted host is configured by default.
- You can configure a maximum of 500 trusted IP address or MAC address for a self-defined guard.
- Trusted hosts can be configured in self-defined guard configuration mode.
- If you do not want to monitor a host, you can run the following commands to trust the host. This trusted host can send ICMP packets to the CPU, without any rate limiting or alarm reporting. You can configure the mask so that no host in one network segment is monitored.
- You must configure the **match** type before configuring trusted hosts. If the packet type is IPv4 in the **match** policy, you are not allowed to configure trusted IPv6 addresses. If the packet type is IPv6 in the match policy, you are not allowed to configure trusted IPv4 addresses.
- If the **match** type is not configured, the system prints the log "%ERROR: Please configure match rule first."
- If a trusted IPv4 host is added but **etype** is not IPv4 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv4 trusted host."
- If a trusted IPv6 host is added but **etype** is not IPv6 in the **match** policy, the system prints the log "%ERROR: Match type can't support IPv6 trusted host."
- If the table of trusted hosts is full, the system prints the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If a trusted host cannot be deleted, the system prints the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If a host cannot be trusted, the system prints the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the host to trust already exists, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the host to delete from the trusted table does not exist, the system prints the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.
- If the memory cannot be allocated to a trusted host, the system prints the log "%ERROR: Failed to allocate memory." to notify the administrator.

▾ Enabling a Self-Defined Guard

- Mandatory.
- You have to configure at least one policy between host-based self-defined guard policy and port-based self-defined guard policy. Otherwise, the self-defined guard cannot be enabled.
- If a self-defined guard is disabled, the system automatically clears monitored hosts.
- Self-defined guards can be configured in self-defined guard configuration mode or interface configuration mode.

- If a self-defined guard policy is not completely configured, the self-defined guard cannot be enabled and a prompt is displayed to notify hosts of the missing policy configurations.
- If the name of a self-defined guard does not exist, the system prints the log "%ERROR: The name is not exist."
- If the match type is not configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't match any type."
- If no policy is configured for a self-defined guard, the system prints the log "%ERROR: name (name of the self-defined guard) doesn't specify any policy."

Verification

When a host in the network sends packets to a switch configured with a self-defined NFPP guard, check whether these packets can be sent to the CPU.

- If the rate of packets from an untrusted host exceeds the attack threshold, an attack log is displayed.
- If an isolated entry is created for the attacker, an isolation log is displayed.

Related Commands

Configuring the Name of a Self-defined Guard

Command	define <i>name</i>
Parameter Description	name: Indicates the name of a self-defined guard.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuring Match Fields of a Self-defined Guard

Command	match [<i>etype</i> <i>type</i>] [src-mac <i>smac</i> [src-mac-mask <i>smac_mask</i>]] [dst-mac <i>dmac</i> [dst-mac-mask <i>dst_mask</i>]] [protocol <i>protocol</i>] [src-ip <i>sip</i> [src-ip-mask <i>sip-mask</i>]] [src-ipv6 <i>sipv6</i> [src-ipv6-masklen <i>sipv6-masklen</i>]] [dst-ip <i>dip</i> [dst-ip-mask <i>dip-mask</i>]] [dst-ipv6 <i>dipv6</i> [dst-ipv6-masklen <i>dipv6-masklen</i>]] [src-port <i>sport</i>] [dst-port <i>dport</i>]
Parameter Description	<i>type</i> : Indicates the type of Ethernet link-layer packets. <i>smac</i> : Indicates the source MAC address. <i>smac_mask</i> : Indicates the mask of the source MAC address. <i>dmac</i> : Indicates the destination MAC address. <i>dst_mask</i> : Indicates the mask of the destination MAC address. <i>protocol</i> : Indicates the protocol number of IPv4/IPv6 packets. <i>sip</i> : Indicates the source IPv4 address. <i>sip-mask</i> : Indicates the mask of the source IPv4 address. <i>sipv6</i> : Indicates the source IPv6 address. <i>sipv6-masklen</i> : Indicates the mask length of the source IPv6 address. <i>dip</i> : Indicates the destination IPv4 address.

	<p><i>dip-mask</i>: Indicates the mask of the destination IPv4 address.</p> <p><i>dipv6</i>: Indicates the destination IPv6 address.</p> <p><i>dipv6-masklen</i>: Indicates the mask length of the destination IPv6 address.</p> <p><i>sport</i>: Indicates the ID of the source transport-layer port.</p> <p><i>dsport</i>: Indicates the ID of the destination transport-layer port.</p>
Command Mode	Self-defined guard configuration mode
Usage Guide	Create a new self-defined guard and specify the packet fields matched by this guard.

📌 Configuring the Global Rate Limit and Attack Threshold of a Self-defined Guard

Command	global-policy { per-src-ip per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter Description	<p>per-src-ip: Collects rate statistics for host identification based on the source IP address, VLAN ID, and port.</p> <p>per-src-mac: Collects rate statistics for host identification based on the source MAC address, VLAN ID, and port.</p> <p>per-port: Collects rate statistics based on each packet receiving port.</p> <p><i>rate-limit-pps</i>: Indicates the rate limit.</p> <p><i>attack-threshold-pps</i>: Indicates the attack threshold.</p>
Command Mode	Self-defined guard configuration mode
Usage Guide	Before creating a self-defined guard type, you must specify rate statistic classification rules for this type, namely, source IP address-based host identification, source MAC address-based host identification, host-based self-defined packet rate statistics, or port-based rate statistics, and specify the rate limits and attack thresholds for the specified rules.

📌 Configuring the Global Isolation Period of a Self-defined Guard

Command	isolate-period [<i>seconds</i> permanent]
Parameter Description	<p><i>seconds</i>: Indicates the isolation period in the unit of second. It can be set to 0 or any value from 30 to 86,400. The value 0 indicates no isolation.</p> <p>permanent: Indicates permanent isolation.</p>
Command Mode	Self-defined guard configuration mode
Usage Guide	If the isolation period is not 0, a host is isolated and its packets of the self-defined guard type are discarded when the packet rate of the self-defined guard exceeds the attack threshold.

📌 Configuring the Global Monitoring Period of a Self-defined Guard

Command	monitor-period <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the monitoring period in the unit of second. The value ranges from 180 to 86,400.
Command Mode	Self-defined guard configuration mode

Usage Guide	N/A
-------------	-----

▾ Configuring the Maximum Number of Monitored Hosts of a Self-defined Guard

Command	monitored-host-limit <i>number</i>
Parameter Description	<i>number</i> : Indicates the maximum number of monitored hosts, ranging from 1 to 4,294,967,295.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

▾ Configuring Trusted Hosts of a Self-defined Guard

Command	trusted-host { <i>mac mac_mask</i> <i>ip mask</i> <i>IPv6/prefixlen</i> }
Parameter Description	<i>mac</i> : Indicates the MAC address. <i>mac_mask</i> : Indicates the mask of an MAC address. <i>ip</i> : Indicates the IP address. <i>mask</i> : Indicates the mask of an IP address. <i>IPv6/prefixlen</i> : Indicates the IPv6 address and its mask length. all : Used with no to delete all trusted hosts.
Command Mode	Self-defined guard configuration mode
Usage Guide	N/A

▾ Enabling a Self-Defined Guard Globally

Command	define <i>name</i> enable
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard.
Command Mode	NFPP configuration mode
Usage Guide	The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

▾ Enabling a Self-defined Guard on an Interface

Command	nfpp define <i>name</i> enable
Parameter Description	<i>name</i> : Indicates the name of a self-defined guard.
Command Mode	Interface configuration mode
Usage Guide	The self-defined name must exist. The configuration takes effect only after you have configured match , rate-count , rate-limit , and attack-threshold . Otherwise, the configuration fails.

▾ Configuring the Rate Limit and Attack Threshold of a Self-defined Guard on an Interface

Command	nfpp define <i>name</i> policy { per-src-ip per-src-mac per-port } <i>rate-limit-pps</i> <i>attack-threshold-pps</i>
Parameter	<i>name</i> : Indicates the name of a self-defined guard.
Description	per-src-ip : Configures the rate limit and attack threshold of each source IP address. per-src-mac : Configures the rate limit and attack threshold of each source MAC address. per-port : Configures the rate limit and attack threshold of each port. <i>rate-limit-pps</i> : Indicates the rate limit, ranging from 1 to 19,999. <i>attack-threshold-pps</i> : Indicates the attack threshold, ranging from 1 to 19,999.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuration Example

📌 CPU Protection Based on a Self-Defined Guard

Scenario	<ul style="list-style-type: none"> ● Basic guards cannot protect the system with RIP attacks.
Configuration Steps	<ul style="list-style-type: none"> ● Configure a self-defined guard, with the key fields matching RIP packets. ● Configure the rate limit. ● Configure the isolation period. ● Configure trusted hosts.

22.4.8 Configuring Centralized Bandwidth Allocation

Configuration Effect

- Configure centralized bandwidth allocation so that Manage and Protocol packets are first processed when the network is busy.

Notes

- The following condition must be met: Valid percentage range of a type of packets ≤ 100% – Percentage of the sum of the other two types

Configuration Steps

▾ Configuring the Maximum Bandwidth of Specified Packets

- (Mandatory) Manage, Route, and Protocol packets share the same default bandwidth.

▾ Configuring the Maximum Percentage of Specified Packets in the Queue

- (Mandatory) By default, Manage packets occupy 30% of the bandwidth, Route packets occupy 25%, and Protocol packets occupy 45%.

Verification

Send a large number of protocol packets such as OSPF packets to a switch, causing high CPU utilization.

- When the host pings the switch, the pinging must be successful and no packet is lost.

Related Commands

Configuring the Maximum Bandwidth of Specified Packets

Command	<code>cpu-protect sub-interface { manage protocol route} pps pps_value</code>
Parameter Description	<i>pps_value</i> : Indicates the rate limit, ranging from 1 to 100,000.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Maximum Percentage of Specified Packets in the Queue

Command	<code>cpu-protect sub-interface { manage protocol route} percent percent_value</code>
Parameter Description	<i>percent_value</i> : Indicates the percentage of a type of packets in the queue, ranging from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	The following condition must be met: Valid percentage range of a type of packets ≤ 100% – Percentage of the sum of the other two types

Configuration Example

Prioritizing Packets Sent to the CPU Through Centralized Bandwidth Allocation

Scenario	<ul style="list-style-type: none"> ● Various types of mass packets exist in the network and belong to different centralized types.
Configuration Steps	<ul style="list-style-type: none"> ● Configure the maximum bandwidth of specified packets. ● Configure the maximum percentage of specified packets in the queue.
	<pre>Nodexon# configure terminal Nodexon(config)# cpu-protect sub-interface manage pps 5000 Nodexon(config)# cpu-protect sub-interface manage percent 25</pre>

22.4.9 Enabling/Disabling All Guards

Configuration Effect

- Use the (no) all-guard enable command to enable or disable all attack guards so that you do not need to disable or enable them one by one.

Notes

- Only basic guards (ARP, ICMP, IP, DHCP, DHCPv6, and ND) are applied.
- Only the global configuration is applied. Interface-based guard configuration remains the same.
- After the command is executed, basic guards are displayed by using the **show running-config** command.
- The **no all-guard enable** command just packs the **no** commands of all basic guards together. After you run the disabling command, the **no** commands of all basic guards are displayed under the **show running-config** command. After you run the enabling command, the default conditions are displayed under the **show running-config** command.

Configuration Steps

Running (no) all-guard enable in Global Configuration Mode

Verification

When a host sends a large number of packets corresponding to basic guards to a switch, such as ARP/ICMP packets, NFPP guard detection takes effect by default.

- Run the **no all-guard enable** command. With the **show cpu-protect** command used, NFPP ratelimit failure is displayed. With the **show nfpp xx-guard host** command used, no attacker is displayed. With the **show nfpp xx-guard summary** command used, the "disabled" status of guards is displayed.

22.4.10 Configuring NFPP Logging

Configuration Effect

- NFPP obtains a log from the dedicated log buffer at a certain rate, generates a system message, and clears this log from the dedicated log buffer.

Notes

- Logs are continuously printed in the log buffer, even if attacks have stopped.

Configuration Steps

▾ Configuring the Log Buffer Size

- Mandatory.
- If the log buffer is full, new logs replace the old ones.
- If the log buffer overflows, subsequent logs replace the previous ones with all attributes marked with a hyphen (-) is displayed in the log buffer. The administrator needs to increase the log buffer size or the system message generation rate.

▾ Configuring the Log Buffer Rate

- Mandatory.
- The log buffer rate depends on two parameters: the time period and the number of system messages generated in the time period.
- If both of the preceding two parameters are set to 0, system messages are immediately generated for logs but are not stored in the log buffer.

▾ Enabling Log Filtering

- (Optional) Log filtering is disabled by default.
- Logs can be filtered based on an interface or VLAN.
- If log filtering is enabled, logs not meeting the filtering rule are discarded.

▾ Enabling Log Printing

- (Mandatory) Logs are stored in the buffer by default.
- If you want to monitor attacks in real time, you can configure logs to be printed on the screen to export the log information in real time.

Verification

Check whether the configuration takes effect based on the log configuration and the number and interval of printed logs.

Related Commands

▾ Configuring the Log Buffer Size

Command	log-buffer entries <i>number</i>
Parameter	<i>number</i> : Indicates the buffer size in the unit of the number of logs, ranging from 0 to 1,024.
Description	
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring the Log Buffer Rate

Command	log-buffer logs <i>number_of_message interval length_in_seconds</i>
Parameter	<i>number_of_message</i> : Ranges from 0 to 1,024. The value 0 indicates that all logs are recorded in the log

Description	buffer and no system message is generated. <i>length_in_seconds</i> : Ranges from 0 to 86,400 (1 day). The value 0 indicates that logs are not recorded in the log buffer but system messages are instantly generated. This also applies to <i>number_of_message</i> and <i>length_in_seconds</i> . <i>number_of_message/length_in_second</i> indicates the system message generation rate.
Command Mode	NFPP configuration mode
Usage Guide	N/A

▾ Configuring VLAN-based Log Filtering

Command	logging vlan <i>vlan-range</i>
Parameter Description	<i>vlan-range</i> : Records logs in a specified VLAN range. The value format is 1-3,5 for example.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs in the specified VLAN range are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

▾ Configuring Interface-based Log Filtering

Command	logging interface <i>interface-id</i>
Parameter Description	<i>interface-id</i> : Records logs of a specified interface.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs of the specified interface are recorded. Between interface-based log filtering and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

▾ Enabling Log Printing

Command	log-buffer enable
Parameter Description	N/A
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuration Example

▾ Configuring NFPP Logging

23 Configuring DoS Protection

23.1 Overview

Denial of Service (DoS) attacks refer to attacks that cause DoS and aim to put computers or networks out of service.

DoS attacks are diversified in types and can be implemented in many ways, but have one common purpose, that is, prevent victim hosts or networks cannot receive, respond, or process external requests in time. In particular, on a layer-2 (L-2) network, DoS attack packets can be spread in the entire broadcast domain. If hackers maliciously initiate DoS attacks, some operating systems (OSs) may collapse. Nodexon products supports the following anti DoS attack functions:

- Denying land attacks
- Denying invalid TCP packets
- Denying invalid layer-4 (L4) ports

23.2 Applications

Application	Description
Protecting Servers Against DoS Attacks	On a campus network, configure the anti DoS attack function on the devices connected to servers to effectively reduce the negative impacts brought by DoS attacks to servers.

23.2.1 Protecting Servers Against DoS Attacks

As show in Figure 23-1, servers are connected to the core switch. The anti DoS attack function is configured on the core switch to prevent malicious DoS attacks and ensure that servers can provide services normally.

Figure 23-1

Deployment

Enable the function of denying land attacks on the core switch to protect servers against land attacks.

Enable the function of denying invalid TCP packets on the core switch to protect servers against invalid TCP packets.

Enable the function of denying invalid L4 ports on the core switch to protect servers against attacks caused by invalid L4 ports.

23.3 Features

Overview

Feature	Description
Denying Land Attacks	Drop packets with the same source and destination IP addresses or the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.
Denying Invalid TCP Packets	Drop invalid TCP packets on the device to prevent invalid TCP packets from attacking OSs on the network. (For details about the definition of invalid TCP packets, see "Denying Invalid TCP Packets".
Denying Invalid L4 Ports	Drop packets with the same L4 source and destination port IDs on the device to prevent these packets from attacking OSs on the network.

23.3.1 Denying Land Attacks

This function protects servers against land attacks.

Working Principle

In a land attack, the attacker sets the source and destination IP addresses or the L4 source and destination port IDs in a SYN packet to the same address of the target host. Consequently, the attacked host will be trapped in an infinite loop or even collapse when attempting to set up a TCP connection with itself.

If the function of denying land attacks is enabled, the device checks packets based on characteristics of land packets (that is, SYN packets with the same source and destination IP addresses), and drops invalid packets.

Related Configuration

📄 Enabling the Function of Denying Land Attacks

By default, the function of denying land attacks is disabled.

Run the **ip deny land** command to enable or disable the function of denying land attacks.

23.3.2 Denying Invalid TCP Packets

This function protects servers against invalid TCP packets.

Working Principle

There are several flag fields in the TCP packet header:

- SYN: Connection establishment flag. The TCP SYN packet is used to set this flag to 1 to request establishment of a connection.
- ACK: Acknowledgement flag. In a TCP connection, this field must be available in every flag (except the first packet, that is, the TCP SYN packet) as the acknowledgement of the previous packet.
- FIN: Finish flag. When a host receives the TCP packet with the FIN flag, the host disconnects the TCP connection.
- RST: Reset flag. When the IP protocol stack receives a TCP packet that contains a non-existent destination port, it responds with a packet with the RST flag.
- PSH: This flag notifies the protocol stack to submit TCP data to the upper-layer program for processing as soon as possible.

In invalid TCP packets, flag fields are set improperly so that the processing resources of hosts are exhausted or even the system collapses. The following lists several common methods for setting flag fields in invalid TCP packets:

- TCP packets with both the SYN and FIN flags

Normally, a TCP packet cannot contain both the SYN and FIN flags. In addition, RFC does not stipulate how the IP protocol stack should process such invalid packets containing both the SYN and FIN flags. Therefore, the protocol stack of each OS may process such packets in different ways when receiving these packets. Attackers can use this feature to send packets containing both the SYN and FIN flags to identify the OS type and initiate attacks on this OS.

- TCP packets without any flag

Normally, a TCP packet contains at least one of the five flags, including SYN, FIN, ACK, RST, and PSH. The first TCP packet (TCP SYN packet) must contain the SYN flag, and the subsequent packets contain the ACK flag. Based on such

assumptions, some protocol stack does not specify the method for processing TCP packets without any flag, and therefore may collapse if such protocol stack receives TCP packets without any flag. Attackers use this feature to initiate attacks on target hosts.

- TCP packets with the FIN flag but without the ACK flag

Normally, except the first packet (TCP SYN packet), all other packets, including the packets with the FIN flag, contain the ACK flag. Some attackers may send TCP packets with the FIN flag but without the ACK flag to the target hosts, causing breakdown of the target hosts.

- TCP packets with the SYN flag and the source port ID set to a value between 0 and 1,023

Port IDs 0 to 1,023 are known port IDs allocated by the Internet Assigned Numbers Authority (IANA). In most systems, these port IDs can be used only by the system (or root) processes or programs run by privileged users. These ports (0–1023) cannot be used as the source port IDs in the first TCP packets (with the SYN flag) sent by clients.

If the function of denying invalid TCP packets is enabled, the device checks packets based on characteristics of invalid TCP packets, and drops invalid TCP packets.

[Related Configuration](#)

↳ [Enabling the Function of Denying Invalid TCP Packets](#)

By default, the function of denying invalid TCP packets is disabled.

Run the **ip deny invalid-tcp** command to enable or disable the function of denying invalid TCP packets.

23.3.3 Denying Invalid L4 Ports

This function protects servers against invalid L4 ports.

[Working Principle](#)

Attackers sends packets in which the IP address of the target host is the same as the L4 port ID of the host to the host target. As a result, the target host sends TCP connection setup requests to itself. Under such attacks, resources of the target host will soon be exhausted and the system will collapse.

If the function of denying invalid L4 ports is enabled, the device checks the L4 source port ID and destination port ID in the packets. If they are the same, the device drops the packets.

[Related Configuration](#)

↳ [Enabling the Function of Denying Invalid L4 Ports](#)

By default, the function of denying invalid L4 ports is disabled.

Run the **ip deny invalid-l4port** command to enable or disable the function of denying invalid L4 ports.

23.4 Configuration

Configuration Item	Description and Command	
Configuring the Function of Denying Land Attacks	 Optional.	
	ip deny land	Enables the function of denying land attacks.
Configuring the Function of Denying Invalid TCP Packets	 Optional.	
	ipdeny invalid-tcp	Enables the function of denying invalid TCP packets.
Configuring the Function of Denying Invalid L4 Ports	 Optional.	
	ip deny invalid-l4port	Enables the function of denying invalid L4 ports.

23.4.1 Configuring the Function of Denying Land Attacks

Configuration Effect

Enable the function of denying land attacks. Then, the device checks packets based on characteristics of land packets, and drops land packets.

Configuration Steps

▾ Enabling the Function of Denying Land Attacks

- Mandatory.
- Perform this configuration on a device connected to a server.

Verification

- Run the **showipdenyland** command to display the status of the function of denying land attacks.
- After this function is enabled, construct a land attack packet and confirm that this packet cannot be forwarded.

ACL & QoS Configuration

1. Configuring ACL
2. Configuring QoS
3. Configuring MMU

1 Configuring the ACL

1.1 Overview

Access control list (ACL) is also called access list or firewall. It is even called packet filtering in some documents. The ACL defines rules to determine whether to forward or drop data packets arriving at a network interface.

ACLs are classified by function into two types:

- Security ACLs: Used to control data flows that are allowed to pass through a network device.
- Quality of service (QoS) ACLs: Used to classify and process data flows by priority.

ACLs are configured for a lot of reasons. Major reasons include:

- Network access control: To ensure network security, rules are defined to limit access of users to some services (for example, only access to the WWW and email services is permitted, and access to other services such as Telnet is prohibited), or to allow users to access services in a specified period of time, or to allow only specified hosts to access the network.
- QoS: QoS ACLs are used to preferentially classify and process important data flows. For details about the use of QoS ACLs, see the configuration manual related to QoS.

1.2 Applications

Application	Description
Access Control of an Enterprise Network	On an enterprise network, the network access rights of each department, for example, access rights of servers and use permissions of chatting tools (such as QQ and MSN), must be controlled according to requirements.

1.2.1 Access Control of an Enterprise Network

Scenario

Internet viruses can be found everywhere. Therefore, it is necessary to block ports that are often used by viruses to ensure security of an enterprise network as follows:

- Allow only internal PCs to access the server.
- Prohibit PCs of a non-financial department from accessing PCs of the financial department, and prohibit PCs of a non-R&D department from accessing PCs of the R&D department.
- Prohibit the staff of the R&D department from using chatting tools (such as QQ and MSN) during working hours from 09:00 to 18:00.

1.3 Features

Basic Concepts

ACL

ACLs include basic ACLs and dynamic ACLs.

You can select basic or dynamic ACLs as required. Generally, basic ACLs can meet the security requirements. However, experienced hackers may use certain software to access the network by means of IP address spoofing. If dynamic ACLs are used, users are requested to pass identify authentication before accessing the network, which prevents hackers from intruding the network. Therefore, you can use dynamic ACLs in some sensitive areas to guarantee network security.

-
- i** IP address spoofing is an inherent problem of all ACLs, including dynamic ACLs. Hackers may use forged IP addresses to access the network during the validity period of authenticated user identities. Two methods are available to resolve this problem. One is to set the idle time of user access to a smaller value, which increases the difficulty in intruding networks. The other is to encrypt network data using the IPSec protocol, which ensures that all data is encrypted when arriving at a device.
-

ACLs are generally configured on the following network devices:

- Devices between the internal network and the external network (such as the Internet)
- Devices on the border of two network segments
- Devices connected to controlled ports

ACL statements must be executed in strict compliance with their sequence in the ACL. Comparison starts from the first statement. Once the header of a data packet matches a statement in the ACL, the subsequent statements are ignored and no longer checked.

Input/Output ACLs, Filtering Field Template, and Rules

When receiving a packet on an interface, the device checks whether the packet matches any access control entry (ACE) in the input ACL of this interface. Before sending a packet through a interface, the device checks whether the packet matches any ACE in the output ACL of this interface.

When different filtering rules are defined, all or only some rules may be applied simultaneously. If a packet matches an ACE, this packet is processed according to the action policy (permit or deny) defined in this ACE. ACEs in an ACL identify Ethernet packets based on the following fields in the Ethernet packets:

Layer 2 (L2) fields:

- 48-bit source MAC address (containing all 48 bits)
- 48-bit destination MAC address (containing all 48 bits)
- 16-bit L2 type field

Layer 3 (L3) fields:

- Source IP address field (All source IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Destination IP address field (All destination IP address values can be specified, or the subnet can be used to define a type of data flows.)
- Protocol type field

Layer 4 (L4) fields:

- Either a TCP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.
- Either a UDP source or destination port is specified, or both are specified, or the range of the source or destination port is specified.

Filtering fields refer to the fields in packets that can be used to identify or classify packets when an ACE is generated. A filtering field template is a combination of these fields. For example, when an ACE is generated, packets are identified and classified based on the destination IP address field in each packet; when another ACE is generated, packets are identified and classified based on the source IP address field and UDP source port field in each packet. The two ACEs use different filtering field templates.

Rules refer to values of fields in the filtering field template of an ACE. For example, the content of an ACE is as follows:

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering field template is a combination of the following fields: source IP address field, IP protocol field, and TCP destination port field. The corresponding values (rules) are as follows: source IP address = Host 192.168.12.2; IP protocol = TCP; TCP destination port = Telnet.

Figure 1-2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet

i A filtering field template can be a combination of L3 and L4 fields, or a combination of multiple L2 fields. The filtering field template of a standard or an extended ACL, however, cannot be a combination of L2 and L3 fields, a combination

of L2 and L4 fields, or a combination of L2, L3, and L4 fields. To use a combination of L2,L3, and L4 fields, you can use the expert ACLs.

- i An SVI associated with ACLs in the outgoing direction supports the IP standard, IP extended, MAC extended, and expert ACLs.
- i If an MAC extended or expert ACL is configured to match the destination MAC address and is applied to the outgoing direction of the SVI, the related ACE can be configured but cannot take effect. If an IP extended or expert ACL is configured to match the destination IP address, but the destination IP address is not in the subnet IP address range of the associated SVI, the configured ACL cannot take effect. For example, assume that the address of VLAN 1 is **192.168.64.1 255.255.255.0**, an IP extended ACL is created, and the ACE is **deny udp any 192.168.65.1 0.0.0.255 eq 255**. If this ACL is applied to the outgoing interface of VLAN 1, the ACL cannot take effect because the destination IP address is not in the subnet IP address range of VLAN 1. If the ACE is **deny udp any 192.168.64.1 0.0.0.255 eq 255**, the ACL can take effect because the destination IP address is in the subnet IP address range of VLAN 1.
- ✓ On a switch, if ACLs are applied to the outgoing direction of a physical port or an aggregate port (AP), the ACLs can filter only well-known packets (unicast or multicast packets), but not unknown unicast packets. That is, for unknown or broadcast packets, ACLs configured in the outgoing direction of a port does not take effect.
- ✓ On a switch, if the input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared among all ports, the permit and default deny ACEs do not take effect, but other deny ACEs take effect.
- ✓ On a switch, if the input ACL and QoS are shared, the permit ACEs do not take effect, other deny ACEs take effect, and the default deny ACE takes effect after the QoS ACE takes effect.
- ✓ On a switch, you can run the **nonNXOS-security compatible** command to make the permit and deny ACEs take effect at the same time when the port-based input ACL and DOT1X, global IP+MAC binding, port security, and IP source guard are shared.
- ✓ If ACEs are added to an ACL and then the switch is restarted after an ACL is applied to the incoming direction of multiple SVIs, the ACL may fail to be configured on some SVIs due to the limited hardware capacity.
- i If an expert ACL is configured and applied to the outgoing direction of an interface, and some ACEs in this ACL contain the L3 matching information (e.g. the IP address and L4 port), non-IP packets sent to the device from this interface cannot be controlled by the permit and deny ACEs in this ACL.
- i If ACEs of an ACL (IP ACL or expert extended ACL) are configured to match non-L2 fields (such as SIP and DIP), the ACL does not take effect on tagged MPLS packets.

↘ ACL Logging

To allow users better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval respectively for the IPv4 ACL and the IPv6 ACL.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.
-  Only switches support the ACL logging function.

ACL Packet Matching Counters

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL, which can be an IP ACL, MAC ACL, expert ACL, or IPv6 ACL. In addition, you can run the **clear counters access-list** [*acl-id* | *acl-name*] command to reset ACL counters for a new round of statistics.

-  Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.
-  Only switches support the ACL packet matching counters.

Overview

Feature	Description
IP ACL	Control incoming or outgoing IPv4 packets of a device based on the L3 or L4 information in the IPv4 packet header.
MAC Extended ACL	Control incoming or outgoing L2 packets of a device based on the L2 information in the Ethernet packet header.
Expert Extended ACL	Combine the IP ACL and MAC extended ACL into an expert extended ACL, which controls (permits or denies) incoming or outgoing packets of a device using the same rule based on the L2, L3, and L4 information in the packet header.
IPv6 ACL	Control incoming or outgoing IPv6 packets of a device based on the L3 or L4 information in the IPv6 packet header.
ACL80	Customize the matching fields and mask for scenarios where fixed matching fields cannot meet the requirements.
ACL Redirection	Redirect incoming packets of a device that match ACEs to a specified outgoing interface.
Global Security ACL	Make an ACL take effect in the incoming direction of all interfaces, instead of applying the ACL on every interface.
Security Channel	Allow packets to bypass the check of access control applications, such as DOT1X and Web authentication, to meet requirements of some special scenarios.
SVI Router ACL	Enable users in the same VLAN to communicate with each other.

Feature	Description
ACL Logging	Output ACL packet matching logs at a specified interval according to requirements. The logs help users learn the packet matching result of a specified ACE.

1.3.1 IP ACL

The IP ACL implements refined control on incoming and outgoing IPv4 packets of a device. You can permit or deny the entry of specific IPv4 packets to a network according to actual requirements to control access of IP users to network resources.

Working Principle

Define a series of IP access rules in the IP ACL, and then apply the IP ACL either in the incoming or outgoing direction of an interface or globally. The device checks whether the incoming or outgoing IPv4 packets match the rules and accordingly forwards or blocks these packets.

To configure an IP ACL, you must specify a unique name or ID for the ACL of a protocol so that the protocol can uniquely identify each ACL. The following table lists the protocols that can use IDs to identify ACLs and the range of IDs.

Protocol	ID Range
Standard IP	1–99, 1300–1999
Extended IP	100–199, 2000–2699

Basic ACLs include the standard IP ACLs and extended IP ACLs. Typical rules defined in an ACL contain the following matching fields:

- Source IP address
- Destination IP address
- IP protocol number
- L4 source port ID or ICMP type
- L4 destination port ID or ICMP code

The standard IP ACL (ID range: 1–99, 1300–1999) is used to forward or block packets based on the source IP address, whereas the extended IP ACL (ID range: 100–199, 2000–2699) is used to forward or block packets based on a combination of the preceding matching fields.

For an individual ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

- ✔ For routing products, the ICMP code matching field in an ACL rule is ineffective for ICPM packets whose ICPM type is 3. If the ICPM code of ICMP packets to be matched is configured in an ACL rule, the ACL matching result of incoming ICMP packets of a device whose ICPM type is 3 may be different from the expected result.

📌 [Implicit "Deny All Traffic" Rule Statement](#)

At the end of every IP ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 1 permit host 192.168.4.12
```

This ACL permits only packets sent from the source host 192.168.4.12, and denies packets sent from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 1 deny any**.

If the ACL contains only the following statement:

```
access-list 1 deny host 192.168.4.12
```

Packets sent from any host will be denied when passing through this port.

- ! When defining an ACL, you must consider the routing update packets. As the implicit "deny all traffic" statement exists at the end of an ACL, all routing update packets may be blocked.

↘ Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and denies all traffic, all subsequent statements will not be checked.

For example:

```
access-list 101 deny ip any any
access-list 101 permttcp 192.168.12.0 0.0.0.255 eqtelnetany
```

The first rule statement denies all IP packets. Therefore, Telnet packets from the host on the network 192.168.12.0/24 will be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

↘ Configuring an IP ACL

By default, no IP ACL is configured on a device.

Run the **ip access-list { standard | extended } {acl-name | acl-id}** command in global configuration mode to create a standard or an extended IP ACL and enter standard or extended IP ACL mode.

↘ Adding ACEs to an IP ACL

By default, a newly created IP ACL contains an implicit ACE that denies all IPv4 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv4 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv4 packets, add some ACEs to the ACL.

For a standard IP ACL, add ACEs as follows:

- No matter whether the standard IP ACL is a named or number ACL, you can run the following command in standard IP ACL mode to add an ACE:
`[sn] { permit | deny } { hostsource | any | source-source-wildcard } [time-range time-range-name] [log]`
- For a numbered standard IP ACL, you can also run the following command in global configuration mode to add an ACE:
`access-list acl-id { permit | deny } { hostsource | any | source-source-wildcard } [time-range tm-rng-name] [log]`

For an extended IP ACL, you can add ACEs as follows:

- No matter whether the extended IP ACL is a named or numbered ACL, you can run the following command in extended IP ACL mode to add an ACE:
`[sn] { permit | deny } protocol { hostsource | any | source-source-wildcard } { hostdestination | any | destination destination-wildcard } [[precedence precedence [tos tos]] | dscp dscp] [fragment] [time-range time-range-name] [log]`
- For a numbered extended IP ACL, you can also run the following command in global configuration mode to add an ACE:
`access-list acl-id { permit | deny } protocol { hostsource | any | source-source-wildcard } { hostdestination | any | destination destination-wildcard } [[precedence precedence [tos tos]] | dscp dscp] [fragment] [time-range time-range-name] [log]`

📌 Applying an IP ACL

By default, the IP ACL is not applied to any interface/VXLAN, that is, the IP ACL does not filter incoming or outgoing IP packets of the device.

Run the `ip access-group { acl-id | acl-name } { in | out } [reflect]` command in interface/VXLAN configuration mode to apply a standard or an extended IP ACL to a specified interface/VXLAN. By default, a reflexive ACL is disabled on a router. You can run the `reflect` command to enable the reflexive ACL. The working principle of the reflexive ACL is as follows:

- A temporary ACL is automatically generated based on the L3 and L4 information of the traffic originated by the internal network. The temporary ACL is created according to the following principles: The IP protocol number remains unchanged, the source and destination IP addresses are swapped, and the TCP/UDP source and destination ports are also swapped.
- The router allows traffic to enter the internal network only when the L3 and L4 information of the returned traffic exactly matches that of the temporary ACL previously created based on the outgoing traffic.

1.3.2 MAC Extended ACL

The MAC extended ACL implements refined control on incoming and outgoing packets based on the L2 header of packets. You can permit or deny the entry of specific L2 packets to a network, thus protecting network resources against attacks or control users' access to network resources.

Working Principle

Define a series of MAC access rules in the MAC extended ACL, and then apply the ACL to the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an MAC extended ACL, you must specify a unique name or ID for this ACL to uniquely identify the ACL. The following table lists the range of IDs that identify MAC extended ACLs.

Protocol	ID Range
MAC extended ACL	700–799

Typical rules defined in an MAC extended ACL include:

- Source MAC address
- Destination MAC address
- Ethernet protocol type

The MAC extended ACL (ID range: 700–799) is used to filter packets based on the source or destination MAC address and the Ethernet type in the packets.

For an individual MAC extended ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL. However, more statements mean that it is increasingly difficult to read and understand the ACL.

- ✔ If ACEs in an MAC extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the MAC extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

↘ Implicit "Deny All Traffic" Rule Statement

At the end of every MAC extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only packets from the host with the MAC address 00d0.f800.0001, and denies packets from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 700 deny any any**.

Related Configuration

↘ Configuring an MAC Extended ACL

By default, no MAC extended ACL is configured on a device.

Run the **mac access-list extended {acl-name | acl-id}** command in global configuration mode to create an MAC extended ACL and enter MAC extended ACL mode.

↘ Adding ACEs to an MAC Extended ACL

By default, a newly created MAC extended ACL contains an implicit ACE that denies all L2 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an MAC extended ACL as follows:

- No matter whether the MAC extended ACL is a named or numbered ACL, you can run the following command in MAC extended ACL mode to add an ACE:

```
[sn] { permit | deny } { any | host src-mac-addr | src-mac-addrmask } { any | host dst-mac-addr | dst-mac-addrmask } [ethernet-type] [coscos] [innercos] [ time-range tm-rng-name ]
```

- For a numbered MAC extended ACL, you can also run the following command in global configuration mode to add an ACE:

```
access-list acl-id { permit | deny } { any | host src-mac-addr | src-mac-addrmask } { any | host dst-mac-addr | dst-mac-addrmask } [ethernet-type] [coscos] [innercos] [ time-range time-range-name ]
```

📌 **Applying an MAC Extended ACL**

By default, the MAC extended ACL is not applied to any interface, that is, the created MAC extended ACL does not filter incoming or outgoing L2 packets of a device.

Run the **mac access-group { acl-id | acl-name } { in | out }** command in interface/VXLAN configuration mode to apply an MAC extended ACL to a specified interface/VXLAN.

1.3.3 Expert Extended ACL

You can create an expert extended ACL to match the L2 and L3 information in packets using the same rule. The expert extended ACL can be treated as a combination and enhancement of the IP ACL and the MAC extended ACL because the expert extended ACL can contain ACEs in both the IP ACL and the MAC extended ACL. In addition, the VLAN ID can be specified in the expert extended ACL to filter packets.

Working Principle

Define a series of access rules in the expert extended ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an expert extended ACL, you must specify a unique name or ID for this ACL so that the protocol can uniquely identify each ACL. The following table lists the ID range of the expert extended ACL.

Protocol	ID Range
Expert extended ACL	2700–2899

When an expert extended ACL is created, defined rules can be applied to all packets. The device determines whether to forward or block packets by checking whether packets match these rules.

Typical rules defined in an expert extended ACL include:

- All information in the basic ACL and MAC extended ACL
- VLAN ID

The expert extended ACL (ID range: 2700–2899) is a combination of the basic ACL and MAC extended ACL, and can filter packets based on the VLAN ID.

For an individual expert extended ACL, multiple independent statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound with the same ACL.

- ✓ If rules in an expert extended ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the expert extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

↘ Implicit "Deny All Traffic" Rule Statement

At the end of every expert extended ACL is an implicit "deny all traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
access-list 2700 permit 0x0806 any any any any any
```

This ACL permits only ARP packets whose Ethernet type is 0x0806, and denies all other types of packets. This is because the following statement exists at the end of this ACL: **access-list 2700 deny any any any any**.

Related Configuration

↘ Configuring an Expert Extended ACL

By default, no expert extended ACL is configured on a device.

Run the **expert access-list extended {acl-name | acl-id}** command in global configuration mode to create an expert extended ACL and enter expert extended ACL mode.

↘ Adding ACEs to an Expert Extended ACL

By default, a newly created expert extended ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

You can add ACEs to an expert extended ACL as follows:

- No matter whether the expert extended ACL is a named or numbered ACL, you can run the following command in expert extended ACL mode to add an ACE:

```
[sn] { permit | deny } [ protocol ] [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ]
{ source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard |
host destination | any } { host destination-mac-address | any } [ precedence precedence ] [ tos tos ] [ fragment ]
[ range lower upper ] [ time-range time-range-name ]]
```

- For a numbered expert extended ACL, you can also run the following command in expert extended ACL mode to add an ACE:

```
access-list acl-id { permit | deny } [ protocol ] [ ethernet-type ] [ cos [ out ] [ inner in ] ] [ [ VID [ out ] [ inner in ] ] ]
{ source source-wildcard | host source | any } { host source-mac-address | any } { destination destination-wildcard |
host destination | any } { host destination-mac-address | any } [ precedence precedence ] [ tos tos ] [ fragment ]
[ range lower upper ] [ time-range time-range-name ]]
```

↘ Applying an Expert Extended ACL

By default, the expert extended ACL is not applied to any interface, that is, the created expert extended ACL does not filter incoming or outgoing L2 or L3 packets of a device.

Run the **expert access-group { acl-id | acl-name } { in| out }** command in interface/VXLAN configuration mode to apply an expert extended ACL to a specified interface/VXLAN.

1.3.4 IPv6 ACL

The IPv6 ACL implements refined control on incoming and outgoing IPv6 packets of a device. You can permit or deny the entry of specific IPv6 packets to a network according to actual requirements to control access of IPv6 users to network resources.

Working Principle

Define a series of IPv6 access rules in the IPv6 ACL, and then apply the ACL in the incoming or outgoing direction of an interface. The device checks whether the incoming or outgoing IPv6 packets match the rules and accordingly forwards or blocks these packets.

To configure an IPv6 ACL, you must specify a unique name for this ACL.

-  Unlike the IP ACL, MAC extended ACL, and expert extended ACL, you can specify only a name but not an ID for the IPv6 ACL created.
-  Only one IP ACL, or one MAC extended ACL, or one expert extended ACL can be applied to the incoming or outgoing direction of an interface. Besides, one more IPv6 ACL can be applied.

↳ Implicit "Deny All Traffic" Rule Statement

At the end of every IPv6 ACL is an implicit "deny all IPv6 traffic" rule statement. Therefore, if a packet does not match any rule, the packet will be denied.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 host 200::1 any
```

This ACL permits only IPv6 packets from the source host 200::1, and denies IPv6 packets from all other hosts. This is because the following statement exists at the end of this ACL: deny ipv6 any any.

-  Although the IPv6 ACL contains the implicit "deny all IPv6 traffic" rule statement by default, it does not filter ND packets.

↳ Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL is very important. It determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence that rule statements are created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and permits all IPv6 traffic, all subsequent statements will not be checked.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

As the first rule statement permits all IPv6 packets, all IPv6 packets sent from the host 200::1 does not match the subsequent deny rule with the serial number of 20, and therefore will not be denied. After the device finds that packets match the first rule statement, it does not check the subsequent rule statements any more.

Related Configuration

Configuring an IPv6 ACL

By default, no IPv6 ACL is configured on a device.

Run the **ipv6 access-list *acl-name*** command in global configuration mode to create an IPv6 ACL and enter IPv6 ACL mode.

Adding ACEs to an IPv6 ACL

By default, a newly created IPv6 ACL contains an implicit ACE that denies all IPv6 packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all IPv6 packets will be discarded. Therefore, if you want the device to receive or send some specific IPv6 packets, add some ACEs to the ACL.

Run the following command in IPv6 ACL mode to add an ACE:

```
[sn] {permit | deny } protocol{src-ipv6-prefix/prefix-len | hostsrc-ipv6-addr | any} {dst-ipv6-pfix/pfix-len | host dst-ipv6-addr | any} [rangelower upper] [dscpdscp] [flow-label flow-label] [fragment] [time-rangetm-rng-name][log]
```

Applying an IPv6 ACL

By default, the IPv6 ACL is not applied to any interface, that is, the IPv6 ACL does not filter incoming or outgoing IPv6 packets of a device.

Run the **ipv6 traffic-filter *acl-name* { in | out }** command in interface/VXLAN configuration mode to apply an IPv6 ACL to a specified interface/VXLAN.

1.3.5 ACL80

ACL80 refers to the expert advanced ACL, and is also called custom ACL. It filters packets based on the first 80 bytes of every packet. Among these 80 bytes, the SMAC, DMAC, SIP, DIP, and ETYPE fields in a packet are mandatory, and you can specify the remaining 16 bytes.

Working Principle

A packet consists of a number of bytes. ACL80 allows you to match the specified 16 bytes by bit in the first 80 bytes of a packet. Any bit of a 16-byte field can be set to a value (**0** or **1**), indicating whether the bit is compared. When any byte is filtered, three factors are considered: content of the matching field, mask of the matching field, and the start position for matching. Bits of the matching field content are in one-to-one mapping relationship with bits of the matching field mask. The filtering rule specifies the value of the field to be filtered. The filtering field template specifies whether the corresponding field

in the filtering rule should be filtered. (1 indicates that the bit specified in the filtering rule should be matched; 0 indicates that the bit specified in the filtering rule is not matched.) Therefore, when it is required to match a specific bit, you must set the corresponding bit to 1 in the filtering field template. For example, if the bit is set to 0 in the filtering field template, no bit is matched no matter which bit is specified in the filtering rule.

For example,

```
Nodexon(config)#expert access-list advanced name
Nodexon(config-exp-dacl)#permit 00d0f8123456 ffffffff 0
Nodexon(config-exp-dacl)#deny 00d0f8654321 ffffffff 6
```

The custom ACL matches any byte of the first 80 bytes in a L2 data frame according to user' definition, and filters packets accordingly. To properly use a custom ACL, you must have an in-depth understanding about the structure of a L2 data frame. The following shows the first 64 bytes of a L3 data frame (every letter represents a hexadecimal number, and every two letters represent one byte):

```
AA AA AA AA AA AA BB BB BB BB BB BB CC CC DD DD
DD DD EE FF GG HH HH HH II II JJ KK LL LL MM MM
NN NN OO PP QQ QQ RR RR RR RR SS SS SS SS TT TT
UU UU VV VV VV VV WW WW WW WW XY ZZ aa aa bb bb
```

The following table describes the meaning and offset of each letter:

Letter	Meaning	Offset	Letter	Meaning	Offset
A	Destination MAC address	0	O	Time To Live (TTL) field	34
B	Source MAC address	6	P	Protocol number	35
C	VLAN tag field	12	Q	IP checksum	36
D	Data frame length	16	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Cntl field	20	U	TCP destination port	48
H	Org Code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version number	26	XY	IP header length and reserved bit	58
K	TOS field	27	Z	Reserved bit and flags bit	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Miscellaneous	62
N	Flags field	32			

In the above table, the offset of each field is the offset of this field in the tagged 802.3 SNAP packet. In a custom ACL, you can use the rule mask and offset jointly to extract any byte from the first 80 bytes of a data frame, compare the byte with the

rule customized in the ACL, and then filter matched data frames for further processing. Customized rules may be some fixed attributes of data. For example, to obtain all TCP packets, you can define the rule as "06", rule mask as "FF", and offset as "35". Then, the device can use the rule mask and offset jointly to extract the content of TCP protocol number field in a received data frame, and compare the extracted content with the rule to obtain all TCP packets.

-  Only switches support the ACL80.
-  The ACL80 supports filtering of the Ethernet, 803.3 SNAP, and 802.3 LLC packets. If the values of the fields from DSAP to cntl are set to AAAA03, the ACL is used to filter the 803.3 SNAP packets. If the values of the fields from DSAP to cntl are set to E0E003, the ACL is used to filter the 803.3 LLC packets. The value of the cntl field cannot be configured to filter Ethernet packets.
-  The ACL80 can be configured to compare packets with any of the 16 bytes. If the 16 bytes are already used, no ACE can be configured to compare packets with fields in any other bytes.

Related Configuration

↘ [Configuring an Expert Advanced ACL](#)

By default, no expert advanced ACL is configured on a device.

Run the **expert access-list advanced *acl-name*** command in global configuration mode to create an expert advanced ACL and enter expert advanced ACL mode.

↘ [Adding ACEs to an Expert Advanced ACL](#)

By default, a newly created expert advanced ACL contains an implicit ACE that denies all packets. This ACE is hidden from users, but takes effect when the ACL is applied to an interface. That is, all L2 packets will be discarded. Therefore, if you want the device to receive or send some specific L2 packets, add some ACEs to the ACL.

- Run the `[sn] { permit | deny } hex hex-mask offset` command in expert advanced ACL mode to add an ACE to the expert advanced ACL.

↘ [Applying an Expert Advanced ACL](#)

By default, the expert advanced ACL is not applied to any interface, that is, the created expert advanced ACL does not filter incoming or outgoing packets of a device.

Run the **expert access-group *acl-name* { in| out }** command in interface configuration mode to apply an expert advanced ACL to a specified interface.

1.3.6 ACL Redirection

ACL redirection allows a device to analyze received packets and redirect the packets to a specified port for forwarding. To analyze specific incoming packets of a device, you can configure the ACL redirection function to redirect packets meeting rules to a specified port and capture packets on this port for analysis.

Working Principle

Bind different ACL policy to an interface and specify an output destination interface for each policy. When receiving packets on this interface, the device searches ACL policies bound to this interface one by one. If packets match criteria described in a certain policy, the device forwards packets on the destination interface specified by the policy, thus redirecting packets based on traffic.

-  Only switches support the ACL redirection function.
-  ACL redirection takes effect only in the incoming direction of an interface.

Related Configuration

Configuring an ACL

Before configuring ACL redirection, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring ACL Redirection

By default, ACL redirection is not configured on a device.

Run the **redirect destinationinterface** *interface-name* **acl** {*acl-id* | **acl-name**} **in** command in interface configuration mode to configure ACL redirection.

-  You can configure the ACL redirection function only on an Ethernet interface, AP, or SVI.

1.3.7 Global Security ACL

To meet the requirements of security deployment, the port-based ACL is often configured to filter out virus packets and obtain packets with certain characteristics, for example, packets that attack the TCP port. Various virus packets exist in a global network environment, and the identification features of virus packets under each port are identical or similar. Therefore, an ACL is generally created. After the deny ACE for matching virus signatures is added to the ACL, the port-based ACL is applied to each port on the switch to filter out virus packets.

For two reasons, it is not convenient to use the port-based ACLs in antivirus scenarios such as virus filtering. The first reason is that the port-based ACL must be configured on every port, which results in repeated configuration, poor operation performance, and over-consumption of ACL resources. The second reason is that the access control function of the ACL is weakened. As the port-based ACL is used for virus filtering, basic functions of the ACL, such as route update restriction and network access restriction, cannot be used properly. The global security ACL can be used for global antivirus deployment and defense without affecting the port-based ACL. By running only one command, you can make the global security ACL takes effect on all L2 interfaces. In contrast, the port-based ACL must be configured on every interface.

Working Principle

The global security ACL takes effect on all L2 interfaces. When both the global security ACL and the port-based ACL are configured, both take effect. Packets that match the global security ACL are directly filtered out as virus packets. Packets that do not match the global security ACL are still controlled by the port-based ACL. You can disable the global security ACL on some ports so that these ports are not controlled by the global security ACL.

-  The global security ACL is mainly used for virus filtering. Therefore, in an ACL associated with the global security ACL, only the deny ACEs take effect, and the permit ACEs do not take effect.
-  Unlike the secure ACL applied to a port, the global security ACL does not contain the default "deny all traffic" ACE, that is, all packets that do not match the ACL are permitted.
-  A global secure ACL can take effect either on a L2 port or a routed port. That is, it takes effect on all the following types of ports: access port, trunk port, hibird port, routed port, and AP (L2 or L3). The global secure ACL does not take effect on an SVI.
-  You can disable the global security ACL on an individual physical port or AP, but not on a member port of an AP.
-  The global secure ACL supports only the associated IP standard ACL, IP extended ACL, MAC extended ACL and Expert extended ACL.

Related Configuration

▾ [Configuring an ACL](#)

Before configuring the global security ACL, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

▾ [Adding ACEs to an ACL](#)

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL.

▾ [Configuring a Global Security ACL](#)

By default, no global security ACL is configured on a device.

Run the **ip access-group *acl-id* { in | out }** command in global configuration mode to enable the global security ACL.

▾ [Configuring an Exclusive Interface of the Global Security ACL](#)

By default, no exclusive interface is configured for the global security ACL on a device.

Run the **no global ip access-group** command in interface configuration to disable the global security ACL on a specified interface.

1.3.8 Security Channel

In some application scenarios, packets meeting some characteristics may need to bypass the checks of access control applications. For example, before DOT1X authentication, users are allowed to log in to a specified website to download the DOT1X authentication client. The security channel can be used for this purpose. When the security channel configuration command is executed to apply a secure ACL globally or to an interface or VXLAN, this ACL becomes a security channel.

Working Principle

The security channel is also an ACL, and can be configured globally or for a specified interface or VXLAN. When arriving at an interface, packets are checked on the security channel. If meeting the matching conditions of the security channel, packets directly enter a switch without undergoing the access control, such as port security, Web authentication, 802.1x, and IP+MAC binding check. A globally applied security channel takes effect on all interfaces except exclusive interfaces.

-  The deny ACEs in an ACL that is applied to a security channel do not take effect. In addition, this ACL does not contain an implicit "deny all traffic" rule statement at the end of the ACL. If packets do not meet matching conditions of the security channel, they are checked according to the access control rules in compliance with the relevant process.
-  You can configure up to eight exclusive interfaces for the global security channel. In addition, you cannot configure interface-based security channel on these exclusive interfaces.
-  If a security channel is applied to an interface while a global security channel exists, this global security channel does not take effect on this interface.
-  If both port-based migratable authentication mode and security channel are applied to an interface, the security channel does not take effect.
-  An IPv6 ACL cannot be configured as a security channel.
-  Only switches support the security channel.

Related Configuration

▾ [Configuring an ACL](#)

Before configuring the security channel, configure an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

▾ [Adding ACEs to an ACL](#)

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, or expert extended ACL.

▾ [Configuring a Security Channel on an Interface](#)

By default, no security channel is configured on an interface of a device.

Run the **security access-group** *{acl-id | acl-name}* command in interface configuration mode to configure the security channel on an interface.

▾ [Configuring a Global Security Channel](#)

By default, no global security channel is configured on a device.

Run the **security global access-group** *{acl-id | acl-name}* command in global configuration mode to configure a global security channel.

▾ [Configuring an Exclusive Interface for the Global Security Channel](#)

By default, no exclusive interface is configured for the global security channel on a device.

Run the **security uplink enable** command in interface configuration mode to configure a specified interface as the exclusive interface of the global security channel.

1.3.9 SVI Router ACL

By default, an ACL that is applied to an SVI also takes effect on L2 packets forwarded within a VLAN and L3 packets forwarded between VLANs. Consequently, users in the same VLAN may fail to communicate with each other. Therefore, a switchover method is provided so that the ACL that is applied to an SVI takes effect only on routing packets between VLANs.

Working Principle

By default, the SVI router ACL function is disabled, and an SVI ACL takes effect on L3 packets forwarded between VLANs and L2 packets forwarded within a VLAN. After the SVI router ACL function is enabled, the SVI ACL takes effect only on L3 packets forwarded between VLANs.

 Only switches support the SVI router ACL.

Related Configuration

▾ [Configuring an ACL](#)

Before configuring the SVI router ACL, configure and apply an ACL. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

▾ [Adding ACEs to an ACL](#)

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ [Applying an ACL](#)

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL. Apply the ACL in SVI configuration mode.

▾ [Configuring the SVI Router ACL](#)

Run the **svi router-acls enable** command in global configuration mode to enable the SVI router ACL so that the ACL that is applied to an SVI takes effect only on packets forwarded at L3, and not on packets forwarded at L2 within a VLAN.

1.3.10 ACL Logging

ACL logging is used to monitor the running status of ACEs in an ACL and provide essential information for routine network maintenance and optimization.

Working Principle

To better learn the running status of ACLs on a device, you can determine whether to specify the ACL logging option as required when adding ACEs. If this option is specified, logs are output when packets matching ACEs are found. ACL logs are

displayed based on ACEs. That is, the device periodically displays ACEs with matched packets and the number of matched packets. An example of the log is as follows:

```
*Sep  9 16:23:06: %ACL-6-MATCH: ACL 100 ACE 10 permit icmp any any, match 78 packets.
```

To control the amount of logs and output frequency, you can configure the log update interval.

-  An ACE containing the ACL logging option consumes more hardware resources. If all configured ACEs contain this option, the ACE capacity of a device will be reduced by half.
-  By default, the log update interval is 0, that is, no log is output. After the ACL logging option is specified in an ACE, you need to configure the log update interval to output related logs; otherwise, logs are not output.
-  For an ACE containing the ACL logging option, if no packet is matched in the specified interval, no packet matching log related to this ACE will be output. If matched packets are found in the specified interval, packet matching logs related to this ACE will be output when the interval expires. The number of matched packets is the total number of packets that match the ACE during the specified interval, that is, the period from the previous log output to the current log output.
-  Only switches support the ACL logging function.
-  You can configure the ACL logging option only for an IP ACL or an IPv6 ACL.

Related Configuration

↘ [Configuring an ACL](#)

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

↘ [Adding ACEs to an ACL](#)

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

↘ [Configuring the Log Update Interval](#)

Run the `{ip | ipv6} access-list log-update interval time` command in the configuration mode to configure the interval at which the ACL logs are output.

↘ [Applying an ACL](#)

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL.

1.3.11 Packet Matching Counters

In addition to ACL logs, packet matching counters provide another choice for routine network maintenance and optimization.

Working Principle

To implement network management, users may want to know whether an ACE has any matched packets and how many packets are matched. ACLs provide the ACE-based packet matching counters. You can enable or disable packet matching counters for all ACEs in an ACL. When a packet matches the ACE, the corresponding counter increments by 1. You can run

the **clear counters access-list** [*acl-id* | *acl-name*] command to reset counters of all ACEs in an ACL for a new round of statistics.

- ❗ Enabling ACL counters requires more hardware entries. In an extreme case, this will reduce by half the number of ACEs that can be configured on a device.
- ✅ You can enable packet matching counters on an IP ACL, MAC ACL, expert ACL, or IPv6 ACL.
- ✅ Only switches support the ACL packet matching counters.

Related Configuration

↘ Configuring an ACL

Configure an ACL before configuring ACEs containing the ACL logging option. For details about how to configure an ACL, see the earlier descriptions about ACL configuration.

↘ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and IPv6 ACL. Note that the ACL logging option must be configured.

↘ Enabling Packet Matching Counters

To enable packet matching counters on an IP ACL, MAC ACL, or expert ACL, run the **{mac | expert | ip} access-list counter** { *acl-id* | *acl-name* } command in global configuration mode.

To enable packet matching counters on an IPv6 ACL, run the **ipv6 access-list counter** *acl-name* command in global configuration mode.

↘ Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

↘ Clearing Packet Matching Counters

Run the **clear counters access-list** [*acl-id* | *acl-name*] command in privileged EXEC mode to reset packet matching counters.

1.3.12 Fragmented Packet Matching Mode

In fragmented packet matching mode, an ACL can implement more refined control on fragmented packets.

Working Principle

IP packets may be fragmented when transmitted on the network. When fragmentation occurs, only the first fragment of the packet contains the L4 information, such as the TCP/UDP port number, ICMP type, and ICMP code, and other fragmented packets do not contain the L4 information. By default, if an ACE contains the fragment flag, fragmented packets except the first fragments are filtered. If an ACE does not contain the fragment flag, all fragmented packets (including the first fragments) are filtered. In addition to this default fragmented packet matching mode, a new fragmented packet matching mode is

provided. You can switch between the two fragmented packet matching modes as required on a specified ACL. In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and packets are fragmented, the first fragments are compared with all the matching fields (including L3 and L4 information) defined in the ACE, and other fragmented packets are compared with only the non-L4 information defined in the ACE.

-  In the new fragmented packet matching mode, if an ACE does not contain the fragment flag and the action is Permit, this type of ACE occupies more hardware entries. In an extreme case, this will reduce by half the number of hardware entries. If Established is configured for filter the TCP flag in an ACE, more hardware entries will be occupied.
-  The ACL will be temporarily ineffective during switchover of the fragmented packet matching mode.
-  In the new fragmented packet matching mode, if an ACE does not contain the fragment flag, the L4 information of packets needs to be compared, and the action is Permit, the ACE checks the L3 and L4 information of the first fragments of packets, and checks only the L3 information of other fragmented packets. If the action is Deny, the ACE checks only the first fragments of packets, and ignores other fragmented packets.
-  In the new fragmented packet matching mode, if an ACE contains the fragment flag, the ACE checks only fragmented packets but not the first fragments of packets no matter whether the action in the ACE is Permit or Deny.
-  Only the IP extended ACL and the expert extended ACL support switching between the two fragmented packet matching modes.
-  Only switches support filtering of fragmented packets.

Related Configuration

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL and expert extended ACL. Note that the fragment option must be added.

Switching the Fragmented Packet Matching Mode

Run the `[no] { ip | expert } access-list new-fragment-mode { acl-id | acl-name }` command in global configuration mode to switch the fragmented packet matching mode.

Applying an ACL

For details about how to apply an ACL, see the earlier descriptions about the IP ACL and expert extended ACL.

1.4 Configuration

Configuration Item	Description and Command
Configuring an IP ACL	 (Optional) It is used to filter IPv4 packets.

Configuration Item	Description and Command	
	ip access-list standard	Configures a standard IP ACL.
	ip access-list extended	Configures an extended IP ACL.
	permit host any time-range log	Adds a permit ACE to a standard IP ACL.
	deny host any time-range log	Adds a deny ACE to a standard IP ACL.
	permit host any host any tos dscp precedence fragment time-range log	Adds a permit ACE to an extended IP ACL.
	deny host any host any tos dscp precedence fragment time-range log	Adds a deny ACE to an extended IP ACL.
	ip access-group in out	Applies a standard or an extended IP ACL.
Configuring an MAC Extended ACL	 (Optional) It is used to filter L2 packets.	
	mac access-list extended	Configures an MAC extended ACL.
	permit any host any host cos inner time-range	Adds a permit ACE to an MAC extended ACL.
	deny any host any host cos inner time-range	Adds a deny ACE to an MAC extended ACL.
	mac access-group in out	Applies an MAC extended ACL.
Configuring an Expert Extended ACL	 (Optional) It is used to filter L2 and L3 packets.	
	expert access-list extended	Configures an expert extended ACL.
	permit cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a permit ACE to an expert extended ACL.
	deny cos inner VID inner host any host any host any precedence tos fragment range time-range	Adds a deny ACE to an expert extended ACL.
	expert access-group in out	Applies an expert extended ACL.
Configuring an IPv6 Extended ACL	 (Optional) It is used to filter IPv6 packets.	
	ipv6 access-list	Configures an IPv6 ACL.
	permit host any host any range dscp flow-label fragment time-range log	Adds a permit ACE to an IPv6 ACL.
	deny host any host any range dscp flow-label fragment time-rangelog	Adds a deny ACE to an IPv6 ACL.
	ipv6 traffic-filter in out	Applies an IPv6 ACL.
Configuring an ACL80	 (Optional) It is used to customize the fields for filter L2 and L3 packets.	
	expert access-list advanced	Configures an expert advanced ACL.
	permit	Adds a permit ACE to an expert advanced ACL.

Configuration Item	Description and Command	
	deny	Adds a deny ACE to an expert advanced ACL.
	expert access-group in out	Applies an expert advanced ACL
Configuring ACL Redirection	 (Optional) It is used to redirect packets meeting the rules to a specified interface.	
	redirect destination interface acl in	Configures ACL redirection.
Configuring a Global Security ACL	 (Optional) It is used to make an ACL take effect globally.	
	ip access-group in out	Applies a global security ACL in global configuration mode.
	no global ip access-group	Configures an interface as the exclusive interface of the global security ACL in interface configuration mode.
Configuring a Security Channel	 (Optional) It is used to enable packets meeting some characteristics to bypass the checks of access control applications, such as the DOT1X and Web authentication.	
	security access-group	Enables the security channel in interface configuration mode.
	security global access-group	Enables the security channel in global configuration mode.
	security uplink enable	Configures an interface as the exclusive interface of the global security channel in interface configuration mode.
Configuring Comments for ACLs	 (Optional) It is used to configure comments for an ACL or ACE so that users can easily identify the functions of the ACL or ACE.	
	list-remark	Configures a comment for an ACL in ACL configuration mode.
	access-list list-remark	Configures a comment for an ACL in global configuration mode.
	remark	Configures a comment for an ACE in ACL configuration mode.

1.4.1 Configuring an IP ACL

Configuration Effect

Configure and apply an IP ACL to an interface/VXLAN to control all incoming and outgoing IPv4 packets of this interface/VXLAN. You can permit or deny the entry of specific IPv4 packets to a network to control access of IP users to network resources.

Notes

N/A

Configuration Steps

Configuring an IP ACL

- (Mandatory) Configure an IP ACL if you want to control access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IP ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an IP ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv4 packets of the device are denied by default.

Applying an IP ACL

- (Mandatory) Apply an IP ACL to a specified interface/VXLAN if you want this ACL take effect.
- You can apply an IP ACL on a specified interface/VXLAN of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the IP ACL:
- Run the **ping** command to verify that the IP ACL takes effect on the specified interface. For example, if an IP ACL is configured to prohibit a host with a specified IP address or hosts in a specified IP address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access related network resources to verify that the IP ACL takes effect on the specified interface. For example, access the Internet or access the FTP resources on the network through FTP.

Related Commands

Configuring an IP ACL

Command	<code>ip access-list { standard extended } {acl-name acl-id}</code>
Parameter Description	<p>standard: Indicates that a standard IP ACL is created.</p> <p>extended: Indicates that an extended IP ACL is created.</p> <p><i>acl-name:</i> Indicates the name of a standard or an extended IP ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".</p> <p><i>acl-id:</i> Indicates the ID that uniquely identifies a standard or extended IP ACL. If this option is configured, a numbered ACL is created. If a standard IP ACL is created, the value range of <i>acl-id</i> is 1–99 and 1300–1999. If an extended IP ACL is created, the value range of <i>acl-id</i> is 100–199 and 2000–2699.</p>
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a standard or an extended IP ACL and enter standard or extended IP ACL

configuration mode. If you want to control access of users to network resources by checking the source IP address of each packet, configure a standard IP ACL. If you want to control access of users to network resources by checking the source or destination IP address, protocol number, and TCP/UDP source or destination port, configure an extended IP ACL.

➤ **Adding ACEs to an IP ACL**

- Add ACEs to a standard IP ACL.

Use either of the following methods to add ACEs to a standard IP ACL:

Command	[<i>sn</i>] { permit deny } { host <i>source</i> any <i>source source-wildcard</i> } [time-range <i>time-range-name</i>] [log]
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs in standard IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	access-list <i>acl-id</i> { permit deny } { host <i>source</i> any <i>source source-wildcard</i> } [time-range <i>tm-rng-name</i>] [log]
Parameter Description	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 1300–1999.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IP packets sent from any host are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are</p>

	<p>filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in global configuration mode. It cannot be used to add ACEs to a named IP ACL.

- Add ACEs to an extended IP ACL.

Use either of the following methods to add ACEs to an extended IP ACL:

Command	<pre>[sn] { permit deny } protocol { host source any source source-wildcard } { host destination any destination destination-wildcard } [[precedence precedence [tos tos]] dscp dscp] [fragment] [time-range time-range-name] [log]</pre>
Parameter Description	<p>sn: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>protocol: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p>source source-wildcard: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered.</p> <p>destination destination-wildcard: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p>any: Indicates that IP packets sent to or from any host are filtered.</p> <p>precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p>tos tos: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p>dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect</p>

	only within this time range. For details about the time range, see the configuration manual of the time range. log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs in extended IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	access-list <i>acl-id</i> { permit deny } <i>protocol</i> { host <i>source</i> any <i>source source-wildcard</i> } { host <i>destination</i> any <i>destination destination-wildcard</i> } [[precedence <i>precedence</i> [tos <i>tos</i>]] dscp <i>dscp</i>] [fragment] [time-range <i>time-range-name</i>] [log]
Parameter Description	<p><i>acl-id</i>: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 100–199 and 2000–1999.</p> <p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp.</p> <p>host source: Indicates that IP packets sent from a host with the specified source IP address are filtered.</p> <p><i>source source-wildcard</i>: Indicates that IP packets sent from hosts in the specified IP network segment are filtered.</p> <p>host destination: Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the any keyword is configured, IP packets sent to any host are filtered.</p> <p><i>destination destination-wildcard</i>: Indicates that IP packets sent to hosts in a specified IP network segment are filtered.</p> <p>any: Indicates that IP packets sent to or from any host are filtered.</p> <p>precedence precedence: Indicates that IP packets with the specified precedence field in the header are filtered.</p> <p>tos tos: Indicates that IP packets with the specified the type of service (TOS) field in the header are filtered.</p> <p>dscp dscp: Indicates that IP packets with the specified the dscp field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IP packets except the first fragments are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>

	log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in extended IP ACL configuration mode. It cannot be used to add ACEs to a named extended IP ACL.

📌 **Applying an IP ACL**

Command	ip access-group { <i>acl-id</i> <i>acl-name</i> } { in out }
Parameter Description	<p><i>acl-id:</i> Indicates that a numbered standard or extended IP ACL will be applied to the interface.</p> <p><i>acl-name:</i> Indicates that a named standard or extended IP ACL will be applied to the interface.</p> <p>in: Indicates that this ACL controls incoming IP packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing IP packets of the interface.</p> <p>reflect: Indicates that the reflexive ACL is enabled.</p>
Command Mode	Interface/VXLAN configuration mode
Usage Guide	This command makes an IP ACL take effect on the incoming or outgoing packets of a specified interface/VXLAN.

Configuration Example

i The following configuration example describes only ACL-related configurations.

📌 **Configuring an IP ACL to Prohibit Departments Except the Financial Department from Accessing the Financial Data Server**

Scenario Figure 1-3	
Configuration Steps	<ul style="list-style-type: none"> ● Configure an IP ACL. ● Add ACEs to the IP ACL.

	<ul style="list-style-type: none"> ● Apply the IP ACL to the outgoing direction of the interface connecting the financial data server.
SW1	<pre>sw1(config)#ip access-list standard 1 sw1(config-std-nacl)#permit 10.1.1.0 0.0.0.255 sw1(config-std-nacl)#deny 11.1.1.1 0.0.0.255 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/3 sw1(config-if-GigabitEthernet 0/3)#ip access-group 1 out</pre>
Verification	<ul style="list-style-type: none"> ● On a PC of the R&D department, ping the financial data server. Verify that the ping operation fails. ● On a PC of the financial department, ping the financial data server. Verify that the ping operation succeeds.
SW1	<pre>sw1(config)#show access-lists ip access-list standard 1 10 permit 10.1.1.0 0.0.0.255 20 deny 11.1.1.0 0.0.0.255 sw1(config)#show access-group ip access-group 1 out Applied On interface GigabitEthernet 0/3</pre>

1.4.2 Configuring an MAC Extended ACL

Configuration Effect

Configure and apply an MAC extended ACL to an interface/VXLAN to control all incoming and outgoing IPv4 packets of this interface/VXLAN. You can permit or deny the entry of specific L2 packets to a network to control access of users to network resources based on L2 packets.

Notes

N/A

Configuration Steps

➤ [Configuring an MAC Extended ACL](#)

- (Mandatory) Configure an MAC extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the MAC address of each user's PC.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The MAC extended ACL takes effect only on the local device, and does not affect other devices on the network.

▾ Adding ACEs to an MAC Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming L2 Ethernet packets of the device are denied by default.

▾ Applying an MAC extended ACL

- (Mandatory) Apply an MAC extended ACL to a specified interface if you want this ACL take effect.
- You can apply an MAC extended ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the MAC extended ACL:
- If an MAC extended ACL is configured to permit or deny some IP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, an MAC extended ACL is configured to prevent a device interface from receiving IP packets (Ethernet type is 0x0800), run the **ping** command for verification.
- If an MAC extended ACL is configured to permit or deny some non-IP packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- You can also construct L2 packets meeting some specified characteristics to check whether the MAC extended ACL takes effect. Typically, prepare two PCs, construct and send L2 packets on one PC, enable packet capturing on another PC, and check whether packets are forwarded as expected (forwarded or blocked) according to the action specified in the ACEs.

Related Commands

▾ Configuring an MAC Extended ACL

Command	mac access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<i>acl-name</i> : Indicates the name of an MAC extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out". <i>acl-id</i> : Indicates the ID that uniquely identifies an MAC extended ACL. If this option is configured, a numbered ACL is created. The value range of <i>acl-id</i> is 700–799.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an MAC extended ACL and enter MAC extended ACL configuration mode. You can configure an MAC extended ACL to control users' access to network resources by checking the L2

	information of Ethernet packets.
--	----------------------------------

➤ Adding ACEs to an MAC Extended ACL

Use either of the following methods to add ACEs to an MAC extended ACL:

- Add ACEs in MAC extended ACL configuration mode.

Command	<code>[sn] { permit deny } { any host src-mac-addr src-mac-addr mask } { any host dst-mac-addr dst-mac-addr mask } [ethernet-type] [cos cos [inner cos]] [time-range tm-rng-name]</code>
Parameter Description	<p>sn: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p>any: Indicates that L2 packets sent from any host are filtered.</p> <p>host src-mac-addr: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p>src-mac-addr mask: Indicates that the source MAC address is reversed.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>host dst-mac-addr: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p>dst-mac-addr mask: Indicates that the destination MAC address is reversed.</p> <p>ethernet-type: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p>cos cos: Indicates that L2 packets with the specified class of service (cos) field in the outer tag are filtered.</p> <p>inner cos: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p>time-range time-range-name: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
Command Mode	MAC extended ACL configuration mode
Usage Guide	Run this command to add ACEs in MAC extended ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an MAC extended ACL in global configuration mode.

Command	<code>access-list acl-id { permit deny } { any host src-mac-addr src-mac-addr mask } { any host dst-mac-addr dst-mac-addr mask } [ethernet-type] [cos cos [inner cos]] [time-range tm-rng-name]</code>
Parameter Description	<p>acl-id: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of <i>acl-id</i> is 700–799.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p>

	<p>host <i>src-mac-addr</i>: Indicates that IP packets sent from a host with the specified source MAC address are filtered.</p> <p><i>src-mac-addr mask</i>: Indicates that the source MAC address is reversed.</p> <p>any: Indicates that L2 packets sent to any host are filtered.</p> <p>host <i>dst-mac-addr</i>: Indicates that IP packets sent to a host with the specified destination MAC address are filtered.</p> <p><i>dst-mac-addr mask</i>: Indicates that the destination MAC address is reversed.</p> <p><i>ethernet-type</i>: Indicates that L2 packets of the specified Ethernet type are filtered.</p> <p>cos <i>cos</i>: Indicates that L2 packets with the specified cos field in the outer tag are filtered.</p> <p>inner <i>cos</i>: Indicates that L2 packets with the specified cos field in the inner tag are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p>
Command Mode	Global configuration mode
Usage Guide	Run this command to add ACEs to a numbered MAC extended ACL in global configuration mode. It cannot be used to add ACEs to a named MAC extended ACL.

📌 [Applying an MAC Extended ACL](#)

Command	mac access-group { <i>acl-id</i> <i>acl-name</i> } { in out }
Parameter Description	<p><i>acl-id</i>: Indicates that a numbered MAC extended IP ACL will be applied to the interface.</p> <p><i>acl-name</i>: Indicates that a named MAC extended IP ACL will be applied to the interface.</p> <p>in: Indicates that this ACL controls incoming L2 packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing L2 packets of the interface.</p>
Command Mode	Interface configuration mode
Usage Guide	This command makes an MAC extended ACL take effect on the incoming or outgoing packets of a specified interface.

[Configuration Example](#)

 The following configuration example describes only ACL-related configurations.

📌 [Configuring an MAC Extended ACL to Restrict Resources Accessible by Visitors](#)

<p>Scenario Figure 1-4</p>	<p>The diagram shows a central switch SW1 with four interfaces: Gi 0/1, Gi 0/2, Gi 0/3, and Gi 0/4. Gi 0/1 connects to a group of PCs labeled 'Employees' (PC1, PC2). Gi 0/2 connects to a group of PCs labeled 'Visitors' (PC1, PC2). Gi 0/3 connects to a group of servers labeled 'Servers', which includes a 'Financial Data Server' with MAC address 00e0.f800.000d and a 'Public Server' with MAC address 00e0.f800.000c. Gi 0/4 connects to the 'Internet' cloud.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an MAC extended ACL. ● Add ACEs to the MAC extended ACL. ● Apply the MAC extended ACL to the outgoing direction of the interface connected to the visitor area so that visitors are allowed to access Internet and the public server of the company, but prohibited from accessing the financial data server of the company. That is, visitors cannot access the server with the MAC address 00e0.f800.000d.
<p>SW1</p>	<pre>sw1(config)#mac access-list extended 700 sw1(config-mac-nacl)#deny any host 00e0.f800.000d sw1(config-mac-nacl)#permit any any sw1(config-mac-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#mac access-group 700 in</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● On a visitor's PC, ping the financial data server. Verify that the ping operation fails. ● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds. ● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.
<p>SW1</p>	<pre>sw1(config)#show access-lists mac access-list extended 700 10 deny any host 00e0.f800.000d etype-any 20 permit any any etype-any sw1(config)#show access-group mac access-group 700 in</pre>

1.4.3 Configuring an Expert Extended ACL

Configuration Effect

Configure and apply an expert extended ACL to an interface/VXLAN to control incoming and outgoing packets of the interface/VXLAN based on the L2 and L3 information, and allow or prohibit the entry of specific packets to the network. In addition, you can configure an expert extended ACL to control all L2 packets based on the VLAN to permit or deny the access of users in some network segments to network resources. Generally, you can use an expert extended ACL if you want to incorporate ACEs of the IP ACL and MAC extended ACL into one ACL.

Configuration Steps

▾ Configuring an Expert Extended ACL

- (Mandatory) Configure an expert extended ACL if you want to control users' access to network resources based on the L2 packet header, for example, the VLAN ID.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert extended ACL takes effect only on the local device, and does not affect other devices on the network.

▾ Adding ACEs to an Expert Extended ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming packets of the device are denied by default.

▾ Applying an Expert Extended ACL

- (Mandatory) Apply an expert extended ACL to a specified interface if you want this ACL take effect.
- You can apply an expert extended ACL in the incoming or outgoing direction of a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the expert extended ACL:
- If IP-based access rules are configured in an expert extended ACL to permit or deny some IP packets, run the **ping** command to verify whether these rules take effect.
- If MAC-based access rules are configured in an expert extended ACL to permit or deny some L2 packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- If VLAN ID-based access rules are configured in an expert extended ACL to permit or deny some L2 packets in some network segments (e.g., to prevent communication between VLAN 1 users and VLAN 2 users), ping PCs of VLAN 2 on a PC of VLAN 1. If the ping operation fails, the rules take effect.

Related Commands

▾ Configuring an Expert Extended ACL

Command	expert access-list extended { <i>acl-name</i> <i>acl-id</i> }
Parameter Description	<p><i>acl-name</i>: Indicates the name of an expert extended ACL. If this option is configured, a named ACL is created. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".</p> <p><i>acl-id</i>: Indicates the ID of an expert extended ACL. If this option is configured, a numbered ACL is created. 1.4.4 Configuring an IPv6 Extended ACL

Configuration Effect

Configure and apply an IPv6 ACL to an interface/VXLAN to control all incoming and outgoing IPv5 packets of this interface/VXLAN. You can permit or deny the entry of specific IPv6 packets to a network to control access of IPv6 users to network resources.

Configuration Steps

📌 Configuring an IPv6 ACL

- (Mandatory) Configure an IP ACL if you want to access of IPv4 users to network resources.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

📌 Adding ACEs to an IPv6 ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, all incoming IPv6 packets of the device are denied by default.

📌 Applying an IPv6 ACL

- (Mandatory) Apply an IPv6 ACL to a specified interface on a device if you want this ACL take effect.
- You can apply an IPv6 ACL on a specified interface/VXLAN of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the IPv6 ACL:
- Run the **ping** command to verify that the IPv6 ACL takes effect on the specified interface. For example, if an IPv6 ACL is configured to prohibit a host with a specified IP address or hosts in a specified IPv6 address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.

- Access network resources, for example, visit an IPv6 website, to check whether the IPv6 ACL takes effect on the specified interface.

Related Commands

▾ Configuring an IPv6 ACL

Command	<code>ipv6 access-list <i>acl-name</i></code>
Parameter Description	<i>acl-name</i> : Indicates the name of a standard or an extended IP ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an IPv6 ACL and enter IPv6 configuration mode.

▾ Adding ACEs to an IPv6 ACL

- To filter TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	<code>[<i>sn</i>] {permit deny} <i>protocol</i> {<i>src-ipv6-prefix/prefix-len</i> host <i>src-ipv6-addr</i> any} {<i>dst-ipv6-pfix/pfix-len</i> host <i>dst-ipv6-addr</i> any} [<i>op dstport</i> range <i>lower upper</i>] [dscp <i>dscp</i>] [flow-label <i>flow-label</i>] [fragment] [time-range <i>tm-rng-name</i>][log]</code>
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>src-ipv6-addr</i>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent from any host are filtered.</p> <p><i>dst-ipv6-pfix/pfix-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent to any host are filtered.</p> <p><i>op dstport</i>: Indicates that TCP or UDP packets are filtered based on the L4 destination port number. The</p>

	<p>value of the op parameter can be eq (equal to), neq (not equal to), gt (greater than), or lt (smaller than).</p> <p>range <i>lower upper</i>: Indicates that TCP or UDP packets with the L4 destination port number in the specified range are filtered.</p> <p>dscp <i>dscp</i>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p> <p>flow-label <i>flow-label</i>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command	IPv6 ACL configuration mode
Mode	
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

- To filter IPv6 packets except for the TCP or UDP packets, add ACEs to an IPv6 ACL as follows:

Command	<pre>[sn] { permit deny } protocol { src-ipv6-prefix/prefix-len host src-ipv6-addr any } { dst-ipv6-pfix/pfix-len host dst-ipv6-addr any } [dscp dscp] [flow-label flow-label] [fragment] [time-range tm-rng-name] [log]</pre>
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>protocol</i>: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate the use, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp.</p> <p><i>src-ipv6-prefix/prefix-len</i>: Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>src-ipv6-addr</i>: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent from any host are filtered.</p> <p><i>dst-ipv6-pfix/pfix-len</i>: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered.</p> <p>host <i>dst-ipv6-addr</i>: Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered.</p> <p>any: Indicates that IPv6 packets sent to any host are filtered.</p>

	<p>dscp <i>dscp</i>: Indicates that IPv6 packets with the specified the dscp field in the header are filtered.</p> <p>flow-label <i>flow-label</i>: Indicates that IPv6 packets with the specified the flow label field in the header are filtered.</p> <p>fragment: Indicates that only fragmented IPv6 packets except the first fragments are filtered.</p> <p>time-range <i>time-range-name</i>: Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range.</p> <p>log: Indicates that logs will be periodically output if packets matching the ACEs are found. For details about logs, see "ACL Logging" in this document.</p>
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

📌 Applying an IPv6 ACL

Command	<code>ipv6 traffic-filter <i>acl-name</i> { in out }</code>
Parameter	<i>acl-name</i> : Indicates the name of an IPv6 ACL.
Description	<p>in: Indicates that this ACL controls incoming IPv6 packets of the interface.</p> <p>out: Indicates that this ACL controls outgoing IPv6 packets of the interface.</p>
Command Mode	Interface configuration mode
Usage Guide	This command makes an IPv6 ACL take effect on the incoming or outgoing packets of the specified interface.

Configuration Example

📌 Configuring an IPv6 ACL to Prohibit the R&D Department from Accessing the Video Server

Scenario Figure 1-6	
Configuration Steps	<ul style="list-style-type: none"> ● Configure an IPv6 ACL. ● Add an ACE to the IPv6 ACL to prevent access to the video server. ● Add an ACE to the IPv6 ACL to permit all IPv6 packets. ● Apply the IPv6 ACL to the incoming direction of the interface connected to the R&D department.

SW1	<pre>sw1(config)#ipv6 access-list dev_deny_ipv6video sw1(config-ipv6-nacl)#deny ipv6 any host 200::1 sw1(config-ipv6-nacl)#permit ipv6 any any sw1(config-ipv6-nacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6video in</pre>
Verification	<ul style="list-style-type: none"> ● On a PC of the R&D department, ping the video server. Verify that the ping operation fails.
SW1	<pre>sw1(config)#show access-lists ipv6 access-list dev_deny_ipv6video 10 deny ipv6 any host 200::1 20 permit ipv6 any any sw1(config)#show access-group ipv6 traffic-filter dev_deny_ipv6video in Applied On interface GigabitEthernet 0/2</pre>

1.4.5 Configuring an ACL80

Configuration Effect

When the IP ACL, MAC extended ACL, expert extended ACL, and IPv6 ACL with fixed matching fields cannot meet requirements, configure the ACL80 to customize the packet fields that need to be matched.

Configuration Steps

↘ **Configuring an Expert Advanced ACL**

- (Mandatory) Configure an expert advanced ACL if you want to implement the ACL80 function. For details about how to configure the expert advanced ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The expert advanced ACL takes effect only on the local device, and does not affect other devices on the network.

↘ **Adding ACEs to an Expert Advanced ACL**

- (Mandatory) Add ACEs to an expert advanced ACL to customize matching fields. If no ACE is added to the expert advanced ACL, the deny ACEs will drop all packets by default. For details about how to add an ACE to an expert advanced ACL, see the related descriptions.

📌 Applying an Expert Advanced ACL

- (Mandatory) Apply an expert advanced ACL to a specified interface if you want this ACL take effect.
- You can apply an expert advanced ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

- Use the following methods to verify the configuration effects of the expert advanced ACL:
- Run the **ping** command to check whether the configurations take effect.
- Construct packets matching the ACEs to check whether ACEs take effect.

Related Commands

📌 Configuring an Expert Advanced ACL

Command	expert access-list advanced <i>acl-name</i>
Parameter Description	<i>acl-name</i> : Indicates the name of an expert advanced ACL. The name is a string of 1 to 99 characters. The ACL name cannot start with numbers (0–9), "in", or "out".
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an expert advanced ACL and enter expert advanced ACL configuration mode.

📌 Adding ACEs to an Expert Advanced ACL

Command	<i>[sn]</i> { permit deny } <i>hex hex-mask offset</i>
Parameter Description	<p><i>sn</i>: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. This sequence number determines the priority of this ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a newly-added ACE will be 110 by default. You can adjust the increment using a command.</p> <p>permit: Indicates that the ACE is a permit ACE.</p> <p>deny: Indicates that the ACE is a deny ACE.</p> <p><i>hex</i>: Indicates the customized matching rule expressed in hexadecimal format, for example, 00d0f800.</p> <p><i>hex-mask</i>: Indicates the matching mask.</p>

	<i>offset</i> : Indicates the start position of matching. For example, if the matching content is 00d0f800, the matching mask is 00ff0000, and start position is 6, the destination MAC address of each packet is compared. All packets whose second byte of the destination MAC address is d0 match this ACE.
Command Mode	Expert advanced ACL configuration mode
Usage Guide	Run this command to add ACEs in expert advanced ACL configuration mode.

➤ **Applying an Expert Advanced ACL**

Command	expert access-group <i>acl-n</i> { in out }
Parameter Description	<i>acl-id</i> : Indicates that a numbered expert advanced ACL will be applied to the interface. <i>acl-name</i> : Indicates that a named expert advanced ACL will be applied to the interface. in : Indicates that this ACL controls incoming L2 packets of the interface. out : Indicates that this ACL controls outgoing L2 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an expert advanced ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

i The following configuration example describes only ACL-related configurations.

➤ **Configuring an ACL80 to Restrict Resources Accessible by Visitors (It is required that visitors and employees cannot communicate with each other, visitors can access the public resource server but not the financial data server of the company.)**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an expert advanced ACL. ● Add an ACE to deny packets sent from PCs in the visitor area (VLAN 3) to employee PCs in VLAN 2. ● Add an ACE to prevent visitors from accessing the financial data server of the company. ● Add an ACE to permit all packets. ● Apply the ACL to the incoming direction of the interface of the switch that connects to the visitor area.
<p>SW1</p>	<pre>sw1(config)#expert access-list advanced acl80-guest sw1(config-exp-dacl)#deny C0A801 FFFFFFFF 42 sw1(config-exp-dacl)#deny 0A010101 FFFFFFFF 42 sw1(config-exp-dacl)#permit 0806 FFFF 24 sw1(config-exp-dacl)#permit 0800 FFFF 24 sw1(config-exp-dacl)#exit sw1(config)#int gigabitEthernet 0/2 sw1(config-if-GigabitEthernet 0/2)#expert access-group acl80-guest in</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● On a visitor's PC, ping the financial data server. Verify that the ping operation fails. ● On a visitor's PC, ping the public resource server. Verify that the ping operation succeeds. ● On a visitor's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails. ● On a visitor's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.
<p>SW1</p>	<pre>sw1(config)#show access-lists expert access-list advanced sss 10 deny C0A801 FFFFFFFF 42 20 deny 0A010101 FFFFFFFF 42 30 permit 0806 FFFF 24 40 permit 0800 FFFF 24 expert access-group acl80-guest in Applied On interface GigabitEthernet 0/2</pre>

1.4.6 Configuring ACL Redirection

Configuration Effect

Configure the ACL redirection function on a specified interface to directly redirect specified packets on the interface to a specified port for further forwarding.

Configuration Steps

Configuring an ACL

- (Mandatory) To implement ACL redirection, you must first configure an ACL, for example, an IP, MAC extended, or expert extended ACL. For details about how to configure an ACL, see the related descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, the ACL redirection function is not available. For details about how to add an ACE to an ACL, see the related descriptions.

Configuring ACL Redirection

- (Mandatory) Enable ACL redirection on a specified interface if you want to implement ACL redirection.
- You can configure the ACL redirection function on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

Send packets matching ACEs on the port where ACL redirection is enabled, and then use the packet capturing software on the destination port to check whether the ACL redirection function takes effect.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuring ACL Redirection

Command	redirect destination interface <i>interface-name</i> acl { <i>acl-id</i> <i>acl-name</i> } in
Parameter Description	<p>interface <i>interface-name</i>: Indicates the name of the destination port for redirection.</p> <p><i>acl-id</i>: Indicates the ID of an ACL.</p> <p><i>acl-name</i>: Indicates the name of an ACL.</p> <p>in: Indicates that incoming packets of the interface are redirected.</p>

Command Mode	Interface configuration mode
Usage Guide	Run this command to redirect incoming packets of the interface that match ACEs to the destination port for further forwarding.

Configuration Example

i The following configuration example describes only ACL-related configurations.

Enabling ACL Redirection to Redirect Packets Sent from the Host 10.1.1.1 to the Packet Capturing Device for Analysis

<p>Scenario Figure 1-8</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configures an IP ACL. Add an ACE to the IP ACL to permit packets sent from the host 10.1.1.1. Enable ACL redirection on the port Gi 0/1, and set the destination port to Gi 0/2.
<p>SW1</p>	<pre>sw1(config)#ip access-list standard 1 sw1 (config-std-nacl)#permit host 10.1.1.1 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# redirect destination interface gigabitEthernet 0/2 acl 1</pre>
<p>Verification</p>	<ul style="list-style-type: none"> Capture packets on PC 2. Ping the video server on PC 1. Verify that ICMP requests sent from PC 1 are captured on PC 2.
<p>SW1</p>	<pre>sw1#show access-lists ip access-list standard 1 10 permit host 10.1.1.1 sw1#show redirect interface gigabitEthernet 0/1</pre>

```
acl redirect configuration on interface gigabitEthernet 0/1
redirect destination interface gigabitEthernet 0/2 acl 1 in
```

1.4.7 Configuring a Global Security ACL

Configuration Effect

Configure a global security ACL to prevent internal PCs of a company from accessing illegal websites or prevent virus from attacking the company's internal network. You can also configure exclusive interfaces to allow specified departments of the company to access external websites.

Configuration Steps

↘ **Configuring an ACL**

- (Mandatory) Configure an ACL if you want to protect the internal network globally. For details about the configuration method, see the earlier descriptions about the ACL.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

↘ **Adding ACEs to an ACL**

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the global security ACL does not exist. For details about how to add an ACE to an ACL, see the related descriptions.

↘ **Configuring a Global Security ACL**

- (Mandatory) Enable the global security function if you want to make the global security ACL take effect.
- You can configure a global security ACL on an access, an aggregate, or a core device based on the distribution of users.

Verification

On the internal network protected by the global security ACL, ping the website or device that are denied by ACEs to check whether the global security ACL takes effect.

Related Commands

↘ **Configuring an ACL**

For details about the configuration method, see the earlier descriptions about the ACL.

↘ **Adding ACEs to an ACL**

For details about the configuration method, see the earlier descriptions about the ACL.

↘ **Configuring a Global Security ACL**

Command	{ ip mac expert } access-group <i>acl-id</i> { in out }
Parameter Description	<i>acl-id</i> : Indicates the ID of an ACL. in : Filters the incoming packets of the device. out : Filters the outgoing packets of the device.
Command Mode	Global configuration mode
Usage Guide	Run this command to enable the global security ACL so that the ACL takes effect on all L2 interfaces of the device.

↘ **Configuring an Exclusive Interface of the Global Security ACL**

Command	no global ip access-group
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to invalidate a global security ACL on a specified interface.

Configuration Example

i The following configuration example describes only ACL-related configurations.

↘ **Configuring a Global Security ACL to Prevent the R&D Department From Accessing the Server of the Sales Department but Allow the Sales Department to Access This Server**

<p>Scenario Figure 1-9</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an extended IP ACL "ip_ext_deny_dst_sale_server". ● Add the ACE that prevents the device to forward packets to the destination host 10.1.1.3/24. ● Configure the ACL "ip_ext_deny_dst_sale_server" as a global security ACL.

	<ul style="list-style-type: none"> ● Configure the interface directly connected to the sales department as the exclusive interface of the global security ACL.
SW1	<pre>sw1(config)#ip access-list extended ip_ext_deny_dst_sale_server sw1(config-ext-nacl)# deny ip any host 10.1.1.3 sw1(config-ext-nacl)#exit sw1(config)#ip access-group ip_ext_deny_dst_sale_server in sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# no global ip access-group</pre>
Verification	<ul style="list-style-type: none"> ● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds. ● On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.
	<pre>sw1#show access-lists ip access-list extended ip_ext_deny_dst_sale_server 10 deny ip any host 10.1.1.3 sw1#show running ! ip access-group ip_ext_deny_dst_sale_server in ! ! ! ! ! ! ! ! ! ! interface GigabitEthernet 0/1 no global ip access-group !</pre>

1.4.8 Configuring a Security Channel

Configuration Effect

Configure a security channel to enable packets meeting the security channel rules to bypass the checks of access control applications. Configure the security channel if an access control application (such as DOT1X) is enabled on an uplink interface of a user, but the user should be allowed to log in to a website to download some resources (for example, downloading the Nodexon SU client) before the DOT1X authentication.

Configuration Steps

▾ Configuring an ACL

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

▾ Adding ACEs to an ACL

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured for an ACL, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

▾ Configuring a Security Channel on a Specified Interface, VXLAN or Globally

- Configure a security channel on an interface if you want this security channel to take effect on the interface. Configure a VXLAN security channel if you want this security channel to take effect on VNI. Configure a global security channel if you want this security channel to take effect globally. You must configure either the interface-based security channel or the global security channel.
- You can configure a security channel on an access, an aggregate, or a core device based on the distribution of users.

▾ Configuring an Exclusive Interface for the Global Security Channel

- (Optional) Configure an interface as the exclusive interface for the global security channel if you do not want the global security channel to take effect on this interface.

▾ Configuring an Access Control Application

- (Optional) You can enable the DOT1X or Web authentication function to verify the security channel function.
- You can configure the access control function on an access, an aggregate, or a core device based on the distribution of users.

Verification

On a PC that is subject to the control of an access control application, ping the resources (devices or servers) that are allowed to bypass the check of the access control application to verify the configuration of the security channel.

Related Commands

▾ Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ Configuring a Security Channel on an Interface

Command	security access-group { <i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure a specified ACL as the security channel on the specified interface.

▾ Configuring a VXLAN Security Channel

Command	security access-group { <i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	VXLAN configuration mode
Usage Guide	Run this command to configure a specified ACL as the security channel on the specified VXLAN.

▾ Configuring a Global Security Channel

Command	security global access-group { <i>acl-id</i> <i>acl-name</i> }
Parameter Description	<i>acl-id</i> : Indicates that ID of the ACL that is configured as the security channel. <i>acl-name</i> : Indicates that name of the ACL that is configured as the security channel.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the specified ACL as the global security channel.

▾ Configuring an Exclusive Interface for the Global Security Channel

Command	security uplink enable
Parameter Description	N/A
Command Mode	Interface configuration mode

Usage Guide	Run this command to configure the specified interface as the exclusive interface of the global security channel.
--------------------	--

Configuration Example

i The following configuration example describes only ACL-related configurations.

Enabling DOT1X Authentication and Configuring a Security Channel to Allow Users to Download the SU Software From the Server Before Authentication

<p>Scenario Figure 1-10</p>	 <p>Dot1x- enabled Devices: VLAN 1 IP Segment : 11.1.1.0/24 Gateway:11.1.1.1/24</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure an expert extended ACL "exp_ext_esc". ● Add an ACE to allow forwarding packets to the destination host 10.1.1.2. ● Add an ACE to permit the DHCP packets. ● Add an ACE to permit the ARP packets. ● On the interface where DOT1X authentication is enabled, configure the ACL "exp_ext_esc" as the security channel.
<p>SW1</p>	<pre>sw1(config)#expert access-list extended exp_ext_esc sw1(config-exp-nacl)# permit ip any any host 10.1.1.2 any sw1(config-exp-nacl)# permit 0x0806 any any any any any sw1(config-exp-nacl)# permit tcp any any any any eq 67 sw1(config-exp-nacl)# permit tcp any any any any eq 68 sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# security access-group exp_ext_esc</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds.

	<ul style="list-style-type: none"> ● On the PCs of R&D department 1 and R&D department 2, ping the server of the sales department. Verify that the ping operations fail.
	<pre>sw1#show access-lists expert access-list extended exp_ext_esc 10 permit ip any any host 10.1.1.2 any 20 permit arp any any any any any 30 permit tcp any any any any eq 67 40 permit tcp any any any any eq 68..... sw1#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 59 bytes interface GigabitEthernet 0/1 security access-group exp_ext_esc</pre>

1.4.9 Configuring the Time Range-Based ACEs

Configuration Effect

Configure the time range-based ACEs if you want some ACEs to take effect or to become invalid in a specified period of time, for example, in some time ranges during a week.

Configuration Steps

▾ Configuring an ACL

- (Mandatory) Configure an ACL if you want ACEs to take effect in the specified time range. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

▾ Adding an ACE with the Time Range Specified

- (Mandatory) Specify the time range when adding an ACE. For details about how to configure the time range, see the configuration manual related to the time range.

▾ Applying an ACL

- (Mandatory) Apply the ACL to a specified interface if you want to make ACEs take effect in the specified time range.

- You can apply an IP ACL on a specified interface of an access, an aggregate, or a core device based on the distribution of users.

Verification

In the time range that the configured ACE takes effect or becomes invalid, run the **ping** command or construct packets matching the ACE to check whether the ACE takes effect or becomes invalid.

Related Commands

▾ Configuring an ACL

For details about the ACL configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ Adding an ACE with the Time Range Specified

For details about the ACE configuration commands, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ Applying an ACL

For details about the command for applying an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Configuration Example

i The following configuration example describes only ACL-related configurations.

▾ Adding an ACE With the Time Range Specified to Allow the R&D Department to Access the Internet Between 12:00 and 13:30 Every Day

<p>Scenario Figure 1-11</p>	 <p>Router Breakout Gateway (NAT) Gi 0/2 IP:110.1.1.2 Internet Gi 0/1 11.1.1.2 SW1 SV2:11.1.1.1 Gi 0/2 SVI:11.1.1.1 Gi 0/1 PC1 PC2 ... R&D Dept.: VLAN 1 IP Segment:10.1.1.0/24 Gateway:10.1.1.1</p>
<p>Configuration</p>	<ul style="list-style-type: none"> ● Configure a time range named "access-internet", and add an entry of the time range between 12:00

<p>Steps</p>	<p>and 13:30 every day.</p> <ul style="list-style-type: none"> ● Configure an IP ACL "ip_std_internet_acl". ● Add an ACE to allow packets with the source IP address in the network segment 10.1.1.0/24, and associate this ACE with the time zone "access-internet". ● Add an ACE to deny packets with the source IP address the network segment 10.1.1.0/24. Access to the Internet is not allowed except in the specified time range. ● Add an ACE to permit all packets. ● Apply the ACL to the outgoing direction of the interface connected to the breakout gateway.

1.4.10 Configuring Comments for ACLs

Configuration Effect

During network maintenance, if a lot of ACLs are configured without any comments, it is difficult to distinguish these ACLs later on. You can configure comments for ACLs to better understand the intended use of ACLs.

Configuration Steps

↘ **Configuring an ACL**

- (Mandatory) Configure an ACL before configuring the security channel. For details about the configuration method, see the earlier descriptions.
- You can configure this ACL on an access, an aggregate, or a core device based on the distribution of users. The configurations take effect only on the local device, and do not affect other devices on the network.

↘ **Configuring Comments for ACLs**

- (Optional) Configure comments for ACLs so that it is easy to manage and understand the configured ACLs.

↘ **Adding ACEs to an ACL**

- (Optional) An ACL may contain zero or multiple ACEs. If no ACE is configured, it is equivalent that the security channel does not take effect. For details about how to add an ACE to an ACL, see the related descriptions.

↘ **Configuring Comments for ACEs**

- (Optional) To facilitate understanding of a configured ACL, you can configure comments for ACEs in addition to comments for the ACL.

Verification

Run the **show access-lists** command on the device to display the comments configured for ACLs.

Related Commands

↘ **Configuring an ACL**

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

↘ **Configuring a Comment for an ACL**

Use either of the following two methods to configure a comment for an ACL:

Command	list-remark <i>comment</i>
Parameter Description	comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

Command	access-list <i>acl-id</i> list-remark <i>comment</i>
Parameter Description	acl-id: Indicates the ID of an ACL. comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

▾ Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

▾ Configuring Comments for ACEs

Use either of the following two methods to configure a comment for an ACE:

Command	[sn] remark <i>comment</i>
Parameter Description	comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters. sn: Indicates the sequence number of ACE.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE. If sn is not specified, the remark is applied to the last ACE.

Command	access-list <i>acl-id</i> sn remark <i>comment</i>
Parameter Description	acl-id: Indicates the ID of an ACL. comment: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100

	characters will be truncated to 100 characters. sn: Indicates the sequence number of ACE.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE. If sn is not specified, the remark is applied to the last ACE.

1.5 Monitoring

Clearing

Description	Command
Clears the ACL packet matching counters.	clear counters access-list [<i>acl-id</i> <i>acl-name</i>]
Clears the counters of packets matching the deny ACEs.	clear access-list counters [<i>acl-id</i> <i>acl-name</i>]

Displaying

Description	Command
Displays the basic ACLs.	show access-lists [<i>acl-id</i> <i>acl-name</i>] [summary]
Displays the redirection ACEs bound to a specified interface. If the interface is not specified, redirection ACEs bound to all interfaces are displayed.	show redirect [interface <i>interface-name</i>]
Displays the ACL configurations applied to an interface.	show access-group [interface <i>interface-name</i>]
Displays the IP ACL configurations applied to an interface.	show ip access-group [interface <i>interface-name</i>]
Displays the MAC extended ACL configurations applied to an interface.	show mac access-group [interface <i>interface-name</i>]
Displays the expert extended ACL configurations applied to an interface.	show expert access-group [interface <i>interface-name</i>]
Displays the IPv6 ACL configurations applied to an interface.	show ipv6 traffic-filter [interface <i>interface-name</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the ACL running process.	debug acl acld event
Debugs the ACL clients.	debug acl acld client-show
Debugs the ACLs created by all ACL	debug acl acld acl-show

clients.	
----------	--

2 Configuring QoS

2.1 Overview

Quality of Service (QoS) indicates that a network can provide a good service capability for specified network communication by using various infrastructure technologies.

When the network bandwidth is sufficient, all data streams can be properly processed; when network congestion occurs, all data streams may be discarded. To meet users' requirements for different applications and different levels of service quality, a network must be able to allocate and schedule resources based on users' requirements and provide different levels of service quality for different data streams. To be specific, the network can process real-time and important data packets in higher priorities, and process non-real-time and common data packets in lower priorities and even discard the data packets upon network congestion.

The "doing the best" forwarding mechanism used by traditional networks cannot meet the requirements any longer and then QoS comes into being. QoS-enabled devices provide transmission QoS quality service. A transmission priority can be assigned to data streams of a type to identify the importance of the data streams. Then, the devices provide forwarding policies for different priorities, congestion mitigation and other mechanisms to provide special transmission services for these data streams. A network environment configured with QoS can provide predictability for network performance, effectively allocate network bandwidth, and reasonably utilize network resources.

2.2 Applications

Application	Description
Interface Rate Limit + Priority Relabeling	Based on different service requirements for a campus network, provide rate control and priority-based processing for outgoing traffic of the teaching building, laboratories and dormitory building.
Priority Relabeling + Queue Scheduling	Provide priority-based processing and bandwidth control for traffic of internal access to servers of an enterprise.

2.2.1 Interface Rate Limit + Priority Relabeling

Scenario

To meet the service requirements of normal teaching, a school puts forwards the following requirements:

- Control the Internet access traffic under 100M and discard packets out of control.
- Control the outgoing traffic of the dormitory building under 50M and discard packets out of control.
- Control the rate of packets with DSCP priority 7 sent from laboratories under 20M, and change the DSCP priorities of these packets whose rates exceed 20M to 16.
- Control the outgoing traffic of the teaching building under 30M and discard packets out of control.

Figure 2-1

Remarks	A school connects GigabitEthernet 0/24 of Switch A to the Internet in the uplink and connects GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A to the teaching building, laboratory and dormitory building in the downlink respectively.
----------------	--

Deployment

- Configure the QoS interface rate limit for the interface G0/24 of Switch A for connecting the Internet.
- Configure the QoS rate limit for packets sent from the dormitory building on Switch A.
- Set the rate limit for packets with the DSCP priority 7 sent from the laboratory to 20M and relabel the DSCP priority of packets out of the rate limit to 16.
- Configure the QoS rate limit for packets sent from the teaching building on Switch A.

2.2.2 Priority Relabeling + Queue Scheduling

Scenario

Configure priority relabeling and queue scheduling to meet the following requirements:

- When the R&D department and market department access servers, the priorities of the server packets are as follows: mail server > file server > salary query server.
- No matter when the HR management department accesses the Internet or servers, the switch processes the corresponding packets in the highest priority.
- Since network congestion often occurs in switch running, in order to ensure smooth business operation, WRR queue scheduling must be used to schedule IP packets for the R&D and market departments to access the mail database, file database, and salary query database based on the ratio of 6:2:1.

Figure 2-2

Remarks	The R&D, market and HR management departments access the interfaces GigabitEthernet 0/1, GigabitEthernet 0/2 and GigabitEthernet 0/3 of Switch A respectively. The salary query server, mail server and file server are connected to GigabitEthernet 0/23 of Switch A.
----------------	--

Deployment

- Configure the CoS values of data streams for accessing different servers to ensure that the switch processes packets for different servers in different priorities.
- Set the default CoS value of the interface to a specific value to ensure that the switch processes packets sent by the HR management department in the highest priority.
- Configure WRR queue scheduling to ensure that data packets are transmitted in a specific quantity ratio.

2.3 Features

Basic Concept

DiffServ

The Differentiated Services (DiffServ) Mode is an IETF system based on which QoS is implemented in Nodexon products. The DiffServ system classifies all packets transmitted in a network into different types. The classification information is included in layer-2/3 packet headers, including 802.1P, IP and IP DSCP priorities.

In a DiffServ-compliant network, all devices apply the same transmission service policy to packets containing the same classification information and apply different transmission service policies to packets containing different classification information. Classification information of packets is either assigned by hosts or other devices in the network or assigned based on different application policies or different packet contents. Based on the classification information carried by packets, a device may provide different transmission priorities for different packet streams, reserve bandwidth for a kind of packet streams, discard certain packets with lower priorities, or take some other actions.

➤ **802.1P(PRI) priority**

The 802.1 P priority is located at the header of a layer-2 packet with the 802.1Q header, and is used in scenarios where layer-3 headers do not need to be analyzed and QoS needs to be implemented at layer 2. Figure 2-3 shows the structure of a layer-2 packet.

Figure 2-3

As shown in Figure 2-3, the 4-byte 802.1Q header contains 2-byte Tag Protocol Identifier (TPID) whose value is 0x8100 and 2-byte Tag Control Information (TCI). The first three bits of the TCI indicate the 802.1P priority.

➤ **IP priority (IP PRE) and DSCP priority**

The priorities of IP packets are identified by the IP PRE and DSCP priority. The Type Of Service (ToS) field of the IPv4 header comprises 8 bits; where the first three bits indicate the IP precedence (IP PRE), ranging from 0 to 7. RFC 2474 redefines the ToS field of the IPv4 header, which is called the Differentiated Services (DS) field. The Differentiated Services Code Point (DSCP) priority is identified by the first 6 bits (bits 0 to 5) of the DS field, and by the first 6 bits of the Traffic Class field in the IPv6 header. Figure 2-4 shows the locations of the IP PRE and DSCP priorities in IPv4/IPv6 packets.

Figure 2-4

➤ **CoS**

Class of Service (COS). Nodexon products convert packet priorities into CoS values to identify the local priorities of the packets and determine the input queue ID when packets are sent from the output interface.

Overview

Feature	Description
Stream Classification	Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services.
Priority Labeling and Mapping	Label packet priorities with specified values and map the values to corresponding CoS values.
Traffic Supervision	Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of the traffic.
Congestion Management	Determine the sequence of data packets sent from an interface based on the priorities of the data packets and ensure that key services can be processed in time when congestion occurs.
Congestion Mitigation	Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

2.3.1 Stream Classification

Stream classification uses certain rules to identify packets with same characteristics and is the prerequisite and basis for distinguishing network services. Stream classification rules are used to distinguish different packets in the network and specify different QoS parameters for packets at different service levels.

Working Principle

Stream classification rules can be matching the PRE or DSCP priorities of IP packets or classifying packets by identifying packet content through an ACL. You can define the binding between multiple streams and stream behaviors by using commands to form policies which can be applied to interfaces for stream classification and processing.

📌 QoS policy

A QoS policy comprises three elements: class, stream behavior and policy.

- Class

A class identifies streams and comprises the class name and class rules. You can define the class rules by using commands to classify packets.
- Stream behavior

Stream behaviors define the QoS actions taken for packets, including priority labeling and traffic supervision for packets.
- Policy

A policy binds a specific class and specific stream behaviors and comprises the policy name, names of the classes bound, and stream behaviors. You can bind a specified class and stream behaviors by using a QoS policy and apply the policy to one or more interfaces.

📌 QoS logical interface group

You can specify a series of interfaces as a QoS logical interface group (including both APs and Ethernet interfaces) and associate polices with the logical interface group for QoS processing. Take rate limit for stream behaviors for example. For packets that meet the rate limit conditions, all interfaces in the same logical interface group share the bandwidth specified by the policy.

Related Configuration

↘ Creating a class

No class is defined by default.

You can run the **class-map** command to create a class and enter the class configuration mode.

↘ Matching an ACL

No rules are defined for a class by default.

In the class configuration mode, you can run the **match access-group** command to define a class rule as matching an ACL. You need to create ACL rules first.

↘ Matching PRE priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip precedence** command to define a class rule as matching PRE priorities of IP packets. The value range of IP PRE is 0 to 7.

↘ Matching DSCP priorities of IP packets

No rules are defined for a class by default.

In the class configuration mode, you can run the **match ip dscp** command to define a class rule as matching DSCP priorities of IP packets. The value range of DHCP priorities is 0 to 63.

↘ Creating a policy

No policy is defined by default.

You can run the **policy-map** command to create a policy and enter the policy configuration mode.

↘ Associating a class

A policy is not associated with any class by default.

In the policy configuration mode, you can run the **class** command to associate a class and enter the policy-class configuration mode.

↘ Binding a stream behavior

A class is not bound to any stream behavior by default.

In the policy-class configuration mode, you can run the **set** command to modify the CoS, DSCP or VID values of a specified stream; where, the CoS value ranges from 0 to 7, the DSCP value ranges from 0 to 63 and the VID value ranges from 1 to

4094. You can run the **police** command to limit the bandwidth and process streams out of the limit for specified streams. The bandwidth limit ranges are determined by products.

↘ Configuring a logical interface group

No logical interface group is defined and an interface is not added to any logical interface group by default.

In the global configuration mode, you can run the **virtual-group** command to create a logical interface group. In the interface configuration mode, you can run the **virtual-group** command to add an interface to a logical interface group. If this logical interface group is not created, you can create the logical interface group and add the interface to the group. You can create 128 logical interface groups, ranging from 1 to 128.

↘ Applying a policy to an interface

No policy is applied to an interface by default.

In the interface configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of the interface. In the global configuration mode, you can run the **service-policy** command to apply a policy in the input/output directions of all interfaces.

2.3.2 Priority Labeling and Mapping

Priorities are used to label the scheduling weights of packets or the priorities of the packets in forwarding. Different packet types have different priority types including 802.1P(PRI), IP PRE and DSCP priorities. Priority labeling and mapping refer to labeling packet priorities with specified values and mapping the values to corresponding CoS values.

Working Principle

After data streams of packets enter a device interface, the device assigns priorities to the packets based on the trust mode configured for the interface. The following describes several trust modes:

- When the interface trust mode is untrust, which means not trusting the priority information carried in packets:
Modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
- When the interface trust mode is trusting CoS:
For packets carrying the 802.1Q tag, modify the CoS value according to the PRI value, CoS-DSCP mapping table, and DSCP-CO mapping table, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
For packets not carrying the 802.1Q tag, modify the CoS value according to the default CoS value (0, which is configurable), COS-DSCP mapping table and DSCP-COS mapping table of the interface, and put the packets into queues based on the final CoS value. For output packets carrying the 802.1Q tag, the packet priority will be modified to the corresponding CoS value.
- When the interface trust mode is trusting DSCP:
For non-IP packets, the processing is the same as that for trusting CoS.

For IP packets, modify the CoS value according to the DSCP value of the packets and the DSCP-CoS mapping table and put the packets into queues based on the final CoS value.

- When the interface trust mode is trusting IP PRE:

For non-IPv4 packets, the processing is the same as that for trusting CoS.

For IPv4 packets, obtain and modify the DSCP priority of the packets according to the IP PRE value of the packets and the IP-PRE-DSCP mapping table, obtain the CoS value according to the DSCP-CoS mapping table, and then put the packets into queues based on the final CoS value.

- When the trust mode and the applied policy of an interface work together:

When the trust mode and the applied policy of an interface work together, the trust mode has a lower priority than the policy and the CoS priority can be obtained according to the DSCP-CoS mapping table.

If a policy is applied to the interface but the policy does not have a configuration for modifying the DSCP and CoS values, the processing will be performed based on the trust mode of the interface.

Related Configuration

📄 Configuring the trust mode of an interface

The default trust mode of an interface is untrust.

In the interface configuration mode, run the **mls qos trust** command to modify the trust mode. The trust mode can be trusting CoS, trusting DSCP or trusting IP PRE.

📄 Configuring the default CoS value of an interface

The default CoS value of an interface is 0.

In the interface configuration mode, run the **mls qos cos** command to modify the default CoS value of the interface, which ranges from 0 to 7.

📄 Labeling the priority of streams

The priorities of streams are not relabeled by default.

In the policy-class configuration mode, run the **set** command to modify the CoS, DSCP and VID values of streams. The CoS value ranges from 0 to 7; the DSCP value ranges from 0 to 63; the VID value ranges from 1 to 4094.

📄 Configuring CoS-to-DSCP Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map cos-dscp** command to configure the CoS-DSCP mapping. The DSCP value ranges from 0 to 63.

📄 Configuring DSCP-to-CoS Map

By default, DSCP 0 to 7 are mapped to CoS 0, DSCP 8 to 15 mapped to CoS 1, DSCP 16 to 23 mapped to CoS 2, DSCP 24 to 31 mapped to CoS 3, DSCP 32 to 39 mapped to CoS 4, DSCP 40 to 47 mapped to CoS 5, DSCP 48 to 55 mapped to CoS 6, and DSCP 56 to 63 mapped to CoS 7.

Run the **mls qos map dscp-cos** command to configure the DSCP-CoS mapping. The CoS value ranges from 0 to 7 and the DSCP value ranges from 0 to 63.

↘ [Configuring IP-PRE-to-DSCP Map](#)

By default, the IP PRE values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the DSCP values 0, 8, 16, 24, 32, 40, 48 and 56 respectively.

Run the **mls qos map ip-prec-dscp** command to configure the IP PRE-DSCP mapping. The DSCP value ranges from 0 to 63.

2.3.3 Traffic Supervision

Supervise the specification of traffic flowing into a network, limit the traffic within a reasonable range, and discard the traffic out of the limit or modify the priority of packets. In addition, the total traffic of an interface can be monitored and the traffic out of the limit will be discarded.

Working Principle

Traffic supervision is used to monitor the specification of traffic flowing into a network and conduct preset supervision actions based on different assessment results. These actions can be:

- Forwarding: Normally forward packets within the traffic limit.
- Discarding: discard packets out of the traffic limit.
- Changing the priority and forwarding: modify the priorities of packets out of the traffic limit and then forward the packets.

Directly discard packets out of the total traffic limit of an interface.

Related Configuration

↘ [Configuring the action to be conducted for traffic out of limit](#)

No action to be conducted for traffic out of limit is configured by default.

In the policy-class configuration mode, run the **police** command to configure the action to be conducted for traffic out of limit to discarding traffic out of limit, or modifying the CoS value or DSCP value. The traffic limit range is determined by products. When the traffic is out of the limit, you can modify the CoS value in the range of 0 to 7 and the DSCP value in the range of 0 to 63.

↘ [Configuring the total traffic limit for an interface](#)

The total traffic limit for an interface is not configured by default.

In the interface configuration mode, run the **rate-limit** command to configure the total traffic limit for an interface in the input and output directions. The traffic limit range is determined by products.

2.3.4 Congestion Management

When the receiving rate of packets exceeds the sending rate of packets, congestion will occur on the sending interface. If no sufficient buffer is provided to store these packets, the packets may be lost. The congestion management mechanism

determines the sequence of data packets to be sent from an interface based on the priorities of the data packets. The congestion management function allows for congestion control by increasing the priorities of important data packets. When congestion occurs, the important data packets are sent in higher priorities to ensure that key services are implemented in time.

Working Principle

A queue scheduling mechanism is used for congestion management and the process is as follows:

- After each packet passes all QoS processing in a switch, the packet will obtain a CoS value finally.
- At the output interface, the device classifies the packets into corresponding sending queues based on the CoS values.
- The output interface selects packets in a queue for sending based on various scheduling policies (SP, WRR, DRR, WFQ, SP+WRR, SP+DRR and SP+WFQ).

▾ Scheduling policy

The queue scheduling policies include SP, WRR, DRR, WFQ, SP+WRR, SP+DRR, and SP+WFQ.

- Strict-Priority (SP) scheduling means scheduling packets strictly following queue IDs. Before sending packets each time, check whether a queue with the first priority has packets to be sent. If yes, the packets in this queue are sent first. If not, check whether a queue with the second priority has packets. Follow the same rules for packets in other queues.
- Weighted Round Robin (WRR) scheduling means scheduling queues in turn to ensure that all queues have certain service time. For example, a 1000 Mbps interface has 8 output queues. The WRR configures a weighted value (5, 5, 10, 20, 20, 10, 20 and 10, which indicate the proportions of obtained resources) for each queue. This scheduling method ensures that a queue with the lowest priority is assigned with at least 50 Mbps bandwidth, which avoids that packets in the queue with the lowest priority are not served for long time when the SP scheduling method is used.
- Deficit Round Robin (DRR) scheduling is similar to the WRR, but applies weight values based on bytes, but not based on time slices.
- Weighted Fair Queueing (WFQ) scheduling provides dynamic and fair queuing and applies weighted values based on bytes, similar to the DRR. When encountering an empty queue, the DRR will shift to the next queue for transmission immediately. If a queue misses its transmission time, the queue must wait for the next time, which is the difference between the WFQ and DRR; therefore, the WFQ is more suitable for processing data packets with variable lengths than the DRR.
- SP+WRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the WRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WRR queues, only after the packets in all SP queues are sent, the packets in WRR queues can be sent.
- SP+DRR scheduling means configuring the SP scheduling for one or more sending queues and configuring the DRR scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and DRR queues, only after the packets in all SP queues are sent, the packets in DRR queues are sent.

- SP+WFQ scheduling means configuring the SP scheduling for one or more sending queues and configuring the WFQ scheduling for the other queues. Among SP queues, only after all packets in the SP queue with the first priority are sent, the packets in the SP queue with the second priority can be sent. Among SP and WFQ queues, only after the packets in all SP queues are sent, the packets in WFQ queues can be sent.

📌 QoS multicast queue

On some products, interface queues are classified into unicast queues and multicast queues. There are 8 unicast queues. All known unicast packets enter corresponding unicast queues for forwarding based on their priorities. There are 1 to 8 multicast queues (depending on products. Certain products do not support multicast queues). Except for known unicast packets, all packets (such as broadcast packets, multicast packets, unknown unicast packets, and mirroring packets) enter corresponding multicast queues for forwarding based on their priorities. Similar to unicast queues, you can configure priority mappings and scheduling algorithms for multicast queues. The **Cos-to-Mc-Queue** command can be used to configure mapping from priorities to multicast queues. At present, multicast queues support the SP, WRR and SP+WRR scheduling algorithms.

📌 Scheduling policy and round robin weight for output queues on an interface

The scheduling policies and round robin weight for output queues are based on global configurations. Some products support both global configurations and interface-based configurations. Interface-based configurations have higher priorities than global configurations. The global scheduling policy works with the corresponding global round robin weight whereas the interface scheduling policy works with the interface round robin weight. If only the global scheduling policy or interface scheduling policy is configured but no corresponding round robin weights are configured, the default round robin weights will work with the scheduling policy.

📌 Queue bandwidth

Some products allow for configuring the guaranteed minimum bandwidth and the limited maximum bandwidth for a queue. A queue configured with the guaranteed minimum bandwidth ensures that the bandwidth for this queue is not smaller than the configured value. A queue configured with the limited maximum bandwidth ensures that the bandwidth for this queue is not greater than the configured value and packets out of the bandwidth limit will be discarded. The bandwidth limits for unicast and multicast queues are configured together on some products whereas configured separately on some other products. In addition, some products allow for configuring bandwidth only for unicast queues.

Related Configuration

📌 Configuring CoS-to-Queue Map

By default, the CoS values 0, 1, 2, 3, 4, 5, 6 and 7 are mapped to the queues 1, 2, 3, 4, 5, 6, 7 and 8 respectively.

Run the **priority-queue cos-map** command to configure the CoS-to-queue mapping. The CoS value ranges from 0 to 7 and the queue value ranges from 1 to 8.

📌 Configuring the scheduling policy for an output queue

By default, the scheduling policy for a global output queue is WRR.

Run the **mls qos scheduler** command to configure the output scheduling policy for a queue. Configurable scheduling policies include SP, WRR, DRR and WFQ. You can also run the **priority-queue** command to configure the scheduling policy as SP.

↘ **Configuring the round robin weight corresponding to the WRR scheduling policy for an output queue**

By default, the weight of a global queue is 1:1:1:1:1:1:1.

Run the **wrr-queue bandwidth** command to configure the round robin weight corresponding to the WRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means longer output time.

↘ **Configuring the round robin weight corresponding to the DRR scheduling policy for an output queue**

By default, the weight of a global queue is 1:1:1:1:1:1:1.

Run the **dr-queue bandwidth** command to configure the round robin weight corresponding to the DRR scheduling policy for an output queue. The configurable weight range is determined by products.

A higher weight means more packet bytes that can be sent.

↘ **Configuring the round robin weight corresponding to the WFQ scheduling policy for an output queue**

By default, the weight of a global queue is 1:1:1:1:1:1:1.

Run the **wfq-queue bandwidth** command to configure the round robin weight corresponding to the WFQ scheduling policy for an output queue. The configurable weight range is determined by products.

↘ **Configuring the bandwidth for a queue**

Run the **qos queue** command to configure the guaranteed minimum bandwidth and the limited maximum bandwidth for each queue. The queue value ranges from 1 to 8 and the guaranteed minimum bandwidth and limited maximum bandwidth value ranges are determined by products. Supported queue types are determined by products.

2.3.5 Congestion Mitigation

Monitor the usage of the output interface queue and reduce the network load by actively discarding packets and adjusting the network traffic when network congestion occurs.

Working Principle

Mitigate congestion by effectively monitoring the network traffic and forecasting occurrence of congestion. Packets need to be discarded to mitigate congestion. Discarding policies include Tail-Drop, Random Early Detection (RED), and Weighted Random Early Detection (WRED).

↘ **Tail-Drop**

Traditional packet loss policies include Tail-Drop. Tail-Drop is effective for all traffic and cannot distinguish service levels. When congestion occurs, data packets at the tail of a queue will be discarded until the congestion is removed.

↘ **RED and WRED**

Hosts running TCP will decrease the rate of sending packets to respond to massive packet loss. After congestion is removed, the hosts increase the rate of sending packets. In this way, Tail-Drop may cause TCP Global Synchronization. When a queue discards multiple TCP packets simultaneously, multiple TCP connections enter the congestion mitigation and slow startup state simultaneously, and the traffic is reduced and adjusted. When congestion is removed, traffic peaks may appear. The process repeats constantly, the network traffic goes up and down suddenly, and the line traffic always fluctuates between the lowest quantity and the highest quantity. When TCP global synchronization occurs, the connection bandwidth cannot be adequately used, which causes bandwidth waste.

To avoid this circumstance, you can use the RED/WRED packet discarding policy. This policy provides a mechanism for discarding packets in random, which avoids TCP global synchronization. When packets of a TCP connection are discarded and sent at a lower rate, packets of other TCP connections are still sent at higher rates. In this way, there are always some TCP connections whose packets are sent at higher rates, which increases the utilization of line bandwidth.

When WRED is used, you can set the lower threshold value and maximum discarding probability for a queue. When the queue length is smaller than the lower threshold value (value range: 1 to 100), WRED does not discard packets. When the queue length is between the higher (100) and lower threshold values, WRED discards packets in random (the longer the queue length, the higher probability of packet discarding. There is a maximum discarding probability). When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

Different from RED, WRED uses priorities to distinguish discarding policies. RED is a special example of WRED. When all CoS values of an interface are mapped to the same lower and higher threshold values, WRED becomes RED.

Related Configuration

▾ Enabling the WRED function

The default packet discarding policy is Tail-Drop.

You can run the **queueing wred** command to enable the WRED function.

▾ Configuring the lower threshold value

When 2 groups of lower threshold values are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect min-threshold** command to configure the lower threshold values for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The lower threshold value ranges from 1 to 100.

When the queue length is smaller than the lower threshold value, WRED does not discard packets. When the queue length is between the lower and higher threshold values, WRED discards packets in random.

▾ Configuring the maximum discarding probability

When 2 groups of maximum discarding probabilities are supported, the default values are 100 and 80 (the number of threshold value groups are determined by products).

In the interface configuration mode, you can run the **wrr-queue random-detect probability** command to configure the maximum discarding probabilities for packets discarded by WRED in each queue. The queue value ranges from 1 to 8. The maximum discarding probability ranges from 1 to 100.

When the queue length is between the lower and higher threshold values, WRED discards packets in random. The longer the queue, the higher the discarding probability. The maximum discarding probability cannot be exceeded. When the queue length is greater than the higher threshold value, WRED discards packets at the maximum discarding probability.

📌 Configuring the CoS-to-threshold mapping

By default, all CoS values are mapped to the first group of threshold values (the number of threshold groups is determined by products).

In the interface configuration mode, you can run the **wrr-queue cos-map** command to configure the CoS-to-threshold group mapping. The CoS value ranges from 0 to 7 and the number of threshold groups is determined by products. Multiple groups of lower threshold values and maximum discarding probabilities can be configured. By configuring the CoS-to-threshold group mapping, you can select the effective threshold group mapped to a CoS value, for example, CoS 0 mapped to the first threshold group, and CoS 1 mapped to the second threshold group. If the packets of CoS 0 and 1 are added to queue 1 for scheduling, the packets of CoS 0 are processed based on the lower threshold values and maximum discarding probabilities in the first group and the packets of CoS 1 are processed based on the lower threshold values and maximum discarding probabilities of the second group.

When all CoS values of an interface are mapped to the same group of threshold values, the enabled WRED becomes RED.

2.4 Configuration

Configuration	Description and Command
Configuring Stream Classification	 (Optional) It is used to create stream classification information.
	class-map Creates a class.
	match access-group Matches ACL rules.
	match ip precedence Matches the PRE priorities of IP packets.
	match ip dscp Matches the DSCP priorities of IP packets.
	policy-map Creates a policy.
	class Associates a class.
	police Binds the bandwidth limit for streams and the action for processing packets out of the limit.
	set Binds the behaviors for modifying the CoS, DSCP and VID values of streams.
virtual-group Creates a logical interface group and adds interfaces to the logical interface group.	
service-policy Applies a policy to an interface.	
Configuring Priority Labeling and Mapping for Packets	 (Optional) It is used to configure the trust mode, default CoS value and various mappings for an interface.
	mls qos trust Modifies the trust mode of an interface.

Configuration	Description and Command	
	mls qos cos	Modifies the default CoS value of the interface.
	mls qos map cos-dscp	Configures the CoS-to-DSCP mapping.
	mls qos map dscp-cos	Configures the DSCP-to-CoS mapping.
	mls qos map ip-precedence-dscp	Configures the IP PRE-to-DSCP mapping.
Configuring Interface Rate Limit	 (Optional) It is used to configure the rate limit for an interface.	
	rate-limit	Configures the traffic limit for an interface.
Configuring Congestion Management	 (Optional) It is used to configure the CoS-to-queue mapping, queue scheduling policies and round robin weight.	
	priority-queue cos-map	Configures the CoS-to-queue mapping.
	priority-queue	Configures the output scheduling policy for a queue to SP.
	mls qos scheduler	Configures the output scheduling policy for a queue.
	wrr-queue bandwidth	Configures the round robin weight corresponding to the WRR scheduling policy for an output queue.
	drr-queue bandwidth	Configures the round robin weight corresponding to the DRR scheduling policy for an output queue.
	wfq-queue bandwidth	Configures the round robin weight corresponding to the WFQ scheduling policy for an output queue.
	qos queue bandwidth	Configures the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.
Configuring Congestion Mitigation	 (Optional) It is used to prevent network congestion by setting packet discarding.	
	queueing wred	Enables the WRED function.
	wrr-queue random-detect min-threshold	Configures the lower threshold value for packets discarded by WRED.
	wrr-queue random-detect probability	Configures the maximum discarding probability for packets discarded by WRED.
	wrr-queue cos-map	Configures the threshold-to-CoS mapping.

2.4.1 Configuring Stream Classification

[Configuration Effect](#)

- Create a class and match classification rules.

- Create a policy, bind a class and stream behaviors, and associate with an interface.

Notes

- The class and policy names cannot comprise more than 31 characters.
- Interface configurations allow for only AP and Ethernet interface configurations. Certain products support policies applied to SVI interfaces through the **service-policy** command. When both physical interfaces and SVI interfaces are configured with policies, the priority of the physical interfaces is higher than that of the SVI interfaces.
- If run the **service-policy** command in global configuration mode, policies will be applied to all interfaces which can be configured with policies.

Configuration Steps

↘ Creating a class and matching ACL rules

- Optional.
- Create a class. In the class configuration mode, match ACL, IP PRE or DSCP.

↘ Creating a policy

- Optional.
- Create a policy. In the policy configuration mode, bind the class and stream behaviors.

↘ Creating a logical interface group and adding interfaces to the logical interface group

- Optional.
- Create a logical interface group and add interfaces to the logical interface group.

↘ Applying a policy to an interface

- Optional.
- Associate a configured policy with a specified interface or logical interface group.

Verification

- Run the **show class-map** command to check whether the class is successfully created and whether rules are successfully matched.
- Run the **show policy-map** command to check whether the policy is successfully created and whether the class and stream behaviors are successfully bound.
- Run the **show mls qos interface** command to check whether the interface is associated with the policy.
- Run the **show virtual-group** command to check the interfaces in the logical interface group.
- Run the **show mls qos virtual-group** command to check whether the logical interface group is associated with the policy.

Related Commands

↘ Creating a class

Command	class-map <i>class-map-name</i>
Parameter Description	<i>class-map-name</i> : Indicates the name of a class to be created. The name cannot comprise more than 31 characters.
Command Mode	Global configuration mode
Usage Guide	-

↘ Matching an ACL

Command	match access-group <i>access-list-number</i>
Parameter Description	<i>access-list-number</i> : Indicates the number of the ACL to be matched.
Command Mode	Class configuration mode
Usage Guide	-

↘ Matching PRE of IP packets

Command	match ip precedence <i>precedence-value... [precedence-value...]</i>
Parameter Description	<i>precedence -value</i> : Indicates the IP PRE to be matched, ranging from 0 to 7.
Command Mode	Class configuration mode
Usage Guide	-

↘ Matching DSCP of IP packets

Command	match ip dscp <i>dscp-value... [dscp-value...]</i>
Parameter Description	<i>dscp -value</i> : Indicates the DSCP to be matched, ranging from 0 to 63.
Command Mode	Class configuration mode
Usage Guide	-

↘ Creating a policy

Command	policy-map <i>policy-map-name</i>
Parameter Description	<i>policy-map-name</i> : Indicates the name of a policy to be created. The name cannot comprise more than 31 characters.
Command Mode	Global configuration mode
Usage Guide	-

↘ Associating a class

Command	class <i>class-map-name</i>
Parameter	<i>class-map-name</i> : Indicates the name of a class to be associated.
Description	
Command Mode	Policy configuration mode
Usage Guide	-

↘ Binding the behaviors for modifying the CoS, DSCP and VID values of streams

Command	set { ip dscp <i>new-dscp</i> cos <i>new-cos</i> vid <i>new-vid</i> }
Parameter	ip dscp <i>new-dscp</i> : Changes the DSCP value of streams to <i>new-dscp</i> , ranging from 0 to 63.
Description	cos <i>new-cos</i> : Changes the CoS value of streams to <i>new-cos</i> , ranging from 0 to 7. vid <i>new-vid</i> : Changes the VLAN ID of streams to <i>new-vid</i> , ranging from 1 to 4094.
Command Mode	Class configuration mode
Usage Guide	-

↘ Binding the bandwidth limit for streams and the action for processing packets out of the limit

Command	police <i>rate-bps burst-byte</i> [exceed-action { drop dscp <i>new-dscp</i> cos <i>new-cos</i> [none-tos] }]
Parameter	<i>rate-bps</i> : Indicates the bandwidth limit per second (KBits). The value range is determined by products.
Description	<i>burst-byte</i> : Indicates the burst traffic limit (Kbytes). The value range is determined by products. drop : Discards packets out of the bandwidth limit. dscp <i>new-dscp</i> : Changes the DSCP value of packets out of the bandwidth limit to <i>new-dscp</i> , ranging from 0 to 63. cos <i>new-cos</i> : Changes the CoS value of packets out of the bandwidth limit to <i>new-cos</i> , ranging from 0 to 7. none-tos : Does not change the DSCP value of packets when changing the CoS value of the packets.
Command Mode	Class configuration mode
Usage Guide	-

↘ Creating a logical interface group and adding interfaces to the logical interface group

Command	virtual-group <i>virtual-group-number</i>
Parameter	<i>virtual-group-number</i> : Indicates the logical interface group number, ranging from 1 to 128.
Description	
Command Mode	Create the logical interface group in the global configuration mode, add the interface to the logical interface group in the interface configuration mode. If no logical interface group exists, you need to create a logical interface group first and then add interfaces to the logical interface group.
Usage Guide	-

↘ Applying a policy to an interface

	<pre>Attached output policy-map: pmap1 Default trust: none Default cos: 0</pre>
	<pre>Nodexon# show virtual-group 1 virtual-group member ----- - 1 Gi0/1 Gi0/2 Nodexon# show mls qos virtual-group 1 Virtual-group: 1 Attached input policy-map: pmap1</pre>

2.4.2 Configuring Priority Labeling and Mapping for Packets

Configuration Effect

- Configure the trust mode and default CoS value of an interface.
- Configure the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

▾ Configuring the trust mode and default CoS value of an interface

- Optional.
- In the interface configuration mode, configure the trust mode and default CoS value of an interface.

▾ Configuring the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings

- Optional.
- Configure various mappings.

Verification

- Run the **show mls qos interface** command to display the trust mode and default CoS value of the interface.
- Run the **show mls qos maps** command to display the CoS-to-DSCP, DSCP-to-CoS and IP-PRE-to-DSCP mappings.

Related Commands

▾ Configuring the trust mode of an interface

Command	mls qos trust { cos ip-precedence dscp }
Parameter	cos: Configures the trust mode of an interface to CoS.
Description	ip-precedence: Configures the trust mode of an interface to IP PRE. dscp: Configures the trust mode of an interface to DSCP.
Command Mode	Interface configuration mode
Usage Guide	-

↘ Configuring the default CoS value of an interface

Command	mls qos cos default-cos
Parameter	<i>default-cos</i> : Configures the default CoS value, ranging from 0 to 7. The default value is 0.
Description	
Command Mode	Interface configuration mode
Usage Guide	-

↘ Configuring CoS-to-DSCP MAP

Command	mls qos map cos-dscp dscp1...dscp8
Parameter	<i>dscp1...dscp8</i> : Indicates the DSCP values mapped to the CoS values. The default CoS values 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Description	
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring DSCP-to-CoS MAP

Command	mls qos map dscp-cos dscp-list to cos
Parameter	<i>dscp-list</i> : Indicates the DSCP list mapped to the CoS values. The default DSCP 0~7 are mapped to CoS 0, DSCP 8~15 mapped to CoS 1, DSCP 16~23 mapped to CoS 2, DSCP 24~31 mapped to CoS 3, DSCP 32~39 mapped to CoS 4, DSCP 40~47 mapped to CoS 5, DSCP 48~55 mapped to CoS 6, and DSCP 56~63 mapped to CoS 7. The DSCP value ranges from 0 to 63.
Description	<i>cos</i> : Indicates the CoS values mapped to the dscp-list, ranging from 0 to 7.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring IP-PRE-to-DSCP MAP

Command	mls qos map ip-prec-dscp dscp1...dscp8
Parameter	<i>dscp1...dscp8</i> : Indicates the DSCP values mapped to the IP PRE values. The default IP PRE 0~7 are mapped to DSCP 0, 8, 16, 24, 32, 40, 48 and 56 respectively. The DSCP value ranges from 0 to 63.
Description	
Command	Global configuration mode

➤ **Configuring the CoS-to-DSCP, DSCP-to-CoS, and IP-PRE-to-DSCP mappings**

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure CoS-to-DSCP to map CoS 0, 1, 2, 3, 4, 5, 6, and 7 to DSCP 7, 14, 21, 28, 35, 42, 49, and 56 respectively. ● Configure DSCP-to-CoS to map DSCP 0, 1, 2, 3, and 4 to CoS 4 and DSCP 11, 12, 13 and 14 to CoS 7. ● Configure IP-PRE-to-DSCP to map IP PRE 0, 1, 2, 3, 4, 5, 6, and 7 to DSCP 31, 26, 21, 15, 19, 45, 47, and 61 respectively.

2.4.3 Configuring Interface Rate Limit

Configuration Effect

- Configure the traffic limit for an interface.

Notes

- The configuration is supported only by Ethernet and aggregate interfaces.

Configuration Steps

```
Nodexon# show policy-map pmap_shiyan

Policy Map pmap_shiyan
  Class cmap_dscp7
    police 20480 128 exceed-action dscp 16

Nodexon# show mls qos interface gigabitEthernet
0/2
Interface: GigabitEthernet 0/2

Ratelimit input:

Ratelimit output:

Attached input  policy-map: pmap_shiyan

Attached output policy-map:
Default trust: dscp
Default cos: 0
```

2.4.4 Configuring Congestion Management

Configuration Effect

- Configure the CoS-to-queue mapping.
- Configure the scheduling policy and round robin weight for an output queue.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

▾ Configuring the CoS-to-unicast and CoS-to-multicast mappings

- Optional.
- Configure the CoS-to-queue mappings. On products supporting multicast queues, you can configure the CoS-to-multicast queue mapping.

▾ Configuring the scheduling policies and round robin weight for unicast and multicast output queues

- Optional.
- Configure the scheduling policy for an output queue and modify the round robin weight. On products supporting multicast queues, you can configure the scheduling policies and round robin weights for multicast queues.

▾ Configuring the guaranteed minimum bandwidth and limited maximum bandwidth for a queue

- Optional.
- Configure the guaranteed minimum bandwidth and limited maximum bandwidth for a queue.

Verification

- Run the **show mls qos queueing** command to display the output queue information.
- Run the **show mls qos scheduler** command to display the scheduling policy for the output queue.
- Run the **show qos bandwidth** command to display the queue bandwidth.

2.4.5 Configuring Congestion Mitigation

Configuration Effect

- Configure the lower threshold value for WRED. When the length of packets in a queue is smaller than the lower threshold value, WRED does not discard packets.
- Configure the maximum discarding probability. When the length of packets in the queue is between the lower and higher threshold values, WRED discards packets in random. The maximum probability for discarding packets is configured.
- Configure the CoS-to-threshold mapping.

Notes

- Interface configurations allow for only AP and Ethernet interface configurations.

Configuration Steps

↳ Enabling the WRED function

- Optional.
- Enable the WRED function if necessary.

↳ Configuring the lower threshold value

- Optional.
- Configure the lower threshold value if necessary.

↳ Configuring the maximum discarding probability

- Optional.
- Configure the maximum discarding probability if necessary.

↳ Configuring the CoS-to-threshold mapping

- Optional.
- Configure the CoS-to-threshold mapping if necessary.

Verification

- Run the **show queueing wred interface** command to display the WRED configuration.

Related Commands

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the QoS library.	debug qos lib [event message]

Debugs the QoS communication server.	debug qos server [event message]
Debugs QoS user command processing.	debug qos mls
Debugs VMSUP configurations.	debug qos vmsup

3 Configuring MMU

3.1 Overview

The Memory Management Unit (MMU) means that the chip buffer is distributed reasonably so that the switching equipment can better deal with all kinds of burst flows.

Flows not steady all the time and various burst flows exist on the network. When the network flow is steady and the bandwidth is sufficient, all the data flows are processed better; when burst flows exist on the network, data flows may be discarded even if the average flow rate does not exceed the bandwidth.

Data packets that enter the switching equipment are stored in the buffer of switching equipment before being forwarded. Normally, data packets stay for a short period of time in the buffer and will be forwarded in microseconds; when there is a burst flow, if the instantaneous rate of burst flow exceeds the processing capacity of the switching equipment, the data packets that cannot be processed in time will be piled up in the switching equipment and packet loss will take place once the buffer is insufficient. In this case, the MMU can be used to reasonably configure the buffer and allocate different buffer sizes to respective services, with a view to optimizing the network.

3.2 Applications

Application	Description
Configuring Large Buffer Application Based on Egress Queue	An enterprise needs a buffer large enough in the SkyDrive service to avoid packet loss for the service flow.

3.2.1 Configuring Large Buffer Application Based on Egress Queue

Scenario

An enterprise needs a buffer large enough in the SkyDrive service to avoid packet loss for the service flow.

As shown in the following figure, equipment A is connected to 5 clients and 35 service servers, where 15 service servers virtualize 15 front end servers.

The main service flow is as follows:

- The client server sends a request packet to the front end server.
- The front end server sends the received request packet to the service server.
- After receiving the request packet, the service server sends a response packet to the front end server.
- After receiving the response packet, the front end server sends it to the client server.
- After receiving the response packet, the client indicates that a session is created successfully.

A many-to-one flow transmission mode exists under this service model:

- The request flows of multiple clients are sent to one front end server.

- The request flows of multiple front end servers are sent to one service server.
- The response flows of multiple service servers are sent to one front end server.
- The response flows of multiple front end servers are sent to one client.

These flows are transmitted through equipment A basically, easily leading to network congestion. Such a problem can be fixed by configuring a large buffer on the equipment.

Figure 3-1

Deployment

- In all the service ports (namely, the ports connecting clients to servers), configure the shared buffer of the queue where the service is as 100%.
- In all the service ports, configure the minimum value for the guaranteed buffer of the queue not in use.
- In all the ports not in use, configure the minimum value for the guaranteed buffers of all the queues.

i For the specific configuration, see the configuration examples in "Configuration".

3.3 Features

Basic Concepts

Cell

Cell is a buffer unit, i.e., the minimum unit for the switching equipment to store packets. The size of each cell varies with the product. One packet can use multiple cells, while one cell can be used by only one packet.

Port group

All the ports physically belonging to one switching chip are collectively called a port group, the buffer of switching equipment is managed in the port group. Take the board card M18000_40XS_CB as an example, this version has two switching chips, so there are two port groups. The first 20 ports belong to Port Group 1, and the back 20 ports belong to Port Group 2.

↘ **Egress queue**

Port egress queues are classified into unicast queues and multicast queues (the number of queues depends on the product). Logically the switching chip is divided into the ingress (incoming direction) and egress (outgoing direction). The egress queue is in the egress direction. Before packets go out of the egress, the enqueue operation needs to be performed for them at the egress queue. Some of our products implement buffer management based on the egress queue.\

Figure 3-2

Currently there are three types of egress queue models:

- There are 8 unicast queues and 8 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are 8 unicast queues and 4 multicast queues at the egress. The well-known unicast packets follow the unicast queue, and all the other packets follow the multicast queue.
- There are only 8 queues at the egress, without differentiating unicast and multicast.

Overview

Feature	Description
Buffer Adjustment	The buffer is adjusted based on the queue. It is the foundation of MMU.
Buffer Monitoring	Buffer monitoring actually means monitoring on the use of the buffer capacity, which facilitates buffer adjustment.
Queue Counting	The received and sent packets of each queue are counted so that the buffer adjustment result can be displayed easily.

3.3.1 Configuring Buffer Adjustment

Buffer adjustment means that the queue of each service has different buffer sizes through some adjustment of the queue buffer so that each service is treated differently and services at different priorities are served differently.

Working Principle

↘ **Working mechanism of caching in hardware**

In terms of hardware, the buffer is managed in the input direction and output direction. The processing mechanism is shown below:

Figure 3-3

During buffer management, the input direction is adjusted to the maximum value to prevent packet loss in the input direction and make packet loss take place in the output direction. Therefore, adjustment is not opened for the buffer in the input direction, and CLI provides buffer adjustment in the output direction only, including the queue guaranteed buffer and queue shared buffer. Buffer adjustment configures the guaranteed buffer threshold and shared buffer threshold of queues to allocate different buffer sizes to queues.

➤ **Guaranteed buffer**

Guaranteed buffer is also called exclusive buffer. This part of buffer is distributed based on each queue. The guaranteed buffer of a queue can be used by this queue only. A fixed guaranteed buffer is allocated to each queue by default. This part of queue enables this queue to forward packets at the normal line rate under the stable flow.

➤ **Buffer mode**

The buffer mode is a global concept, which adjusts the guaranteed buffer and shared buffer based on all the queues of all the panel interfaces. Four buffer modes are supported at present: the normal buffer mode, burst enhanced buffer mode (namely, the large buffer mode), QoS enhanced buffer mode (namely, the small buffer mode) and the flow control enhanced buffer mode.

The specific values for queue guaranteed buffers and shared buffers corresponding to these four buffer modes depend on the product. Set out below are the buffer management characteristics and application scenarios of these modes:

Normal buffer mode

This mode considers three factors of the switch: the burst large flow buffer capacity, QoS scheduling support and flow control support. Support to the above three aspects is relatively balanced without particular bias, so the support degree is moderate.

- Applicable environment:
 - Environment without special requirement for buffer: Since buffer management of this mode is moderate and factors at all aspects are considered, the problem occurrence probability is small;

- Environment where a low speed port exists and the low speed port operates normally and is not in the dormant state: The so-called low speed port means that a port negotiated as 100M appears on the equipment with the port form as 10 gigabit plus gigabit or a port negotiated as 10M appears on the equipment with the port form as gigabit plus 100M;
- Environment with deployed QoS: The support degree is moderate. For input of one port in such an environment, packet loss will take place at the ingress only when five ports are congested at the same time, and then QoS becomes invalid;
- Environment with deployed flow control: The support degree is low to moderate. In such an environment, packet loss will take place at the egress only when traffic of four ports is pumped into one port at the same time, and then flow control becomes invalid.
- Not applicable environment:
 - Since the Burst buffer capacity is moderate under this mode, this mode is not applicable to the environment with the especially significant characteristics of burst large flow;
 - This mode is not applicable to the environment where flow control is not deployed and the packet loss tolerance degree is low because moderate support to QoS is considered under this mode and the characteristic of QoS is packet loss.
- Applications:
 - Campus network environment: It is characterized in that the open environment allows access of low-speed terminals anytime, and the packet loss tolerance degree is high (the packet loss rate of 1% to 2% can be endured according to the empirical value).

Burst enhanced buffer mode

This mode aims to implement enhanced support to the burst large-flow buffer capacity of switch based on factors in three aspects considered for the normal buffer mode, namely, Burst enhancement. Since a contradictory mutual exclusion relationship exists between Burst, QoS and flow control support, QoS and flow control support will be alleviated properly in Burst enhancement mode. The buffer configuration of Burst enhancement mode is characterized in that the restricted output queue buffer is relatively large, enhancing the buffer capacity of the single port queue and overall system and also supporting flow control and QoS.

- Applicable environment:
 - The topology is stable, the type of equipment accessing switch is fixed, and the terminal equipment of low speed network card will not be accessed at will on the switch;
 - The environment with the especially significant characteristics of burst large flow;
 - For the environment with a lower packet loss tolerance degree, since the buffer capacity of a single queue is configured as large as possible, packet loss can be reduced through buffer even if flow control is not enabled;
 - Environment with deployed QoS: The support degree is weak. For input of one port in such an environment, packet loss will take place at the ingress when two ports are congested at the same time, and then QoS becomes invalid;

- Environment with deployed flow control: The support degree is weak. In such an environment, packet loss will take place at the egress only when two ports enable one port at the same time, and then flow control becomes invalid; for flow control deployment under this mode, it is recommended that flow control be enabled on the uplink port accessing the switch only, but not be enabled on the downlink port.
- Not applicable environment:
 - Environment with a low speed port (for the definition of low speed port, see the introduction in the above normal buffer mode): Since the buffer is opened for sharing under this mode, the buffer capacity of a single queue is stronger. If there is a low speed port, the buffer application of a non-low speed port will be affected seriously, leading to a severe packet loss problem of non-low speed port;
 - Multicast network: The reason is similar to that of the situation with a low speed port, and the non-multicast egress may be affected seriously.
- Applications:
 - Nonlinear editing network of the radio and TV station, used together with flow control (so long as flow control is enabled on the uplink port); main characteristics: the topology is stable, there are especially significant characteristics of burst large flow, the packet loss tolerance degree is very low, and QoS is not deployed;
 - IPQAM flow pushing network of radio and TV station; main characteristics: there are especially significant characteristics of burst large flow, and the packet loss tolerance degree is relatively low;
 - Simultaneous network transmission environment; main characteristics: the type of equipment accessing switch is fixed, QoS is not deployed, and the requirement for the bandwidth utilization is relatively high (open sharing of buffer can improve the bandwidth utilization);
 - Video surveillance network; main characteristics: the type of equipment accessing switch is fixed, and the packet loss tolerance degree is relatively low.

QoS enhancement mode

This mode implements enhancement support for QoS based on factors in three aspects considered for the normal buffer mode. Since a contradictory mutual exclusion relationship exists between Burst, QoS and flow control support, the Burst buffer capacity and flow control support will be alleviated properly in QoS enhancement mode. Buffer configuration of the QoS enhancement mode is characterized in that the restricted output queue buffer is relatively small, leading to packet loss at the egress and thus achieving the effect of differentiated service.

- Applicable environment:
 - The packet loss tolerance degree is relatively high, and there is an environment with more low speed ports;
 - Environment with deployed QoS: Strong support can be realized; the environment is characterized in that every egress queue has a guaranteed buffer, and for input of one port, packet loss will take place at the ingress when 15 ports are congested at the same time, and then QoS becomes invalid;
 - Environment with deployed flow control: The support degree is weak. In such an environment, packet loss will take place at the egress only when two ports enable one port at the same time, and then flow control becomes invalid. However, it is different from weak flow control support under the Burst enhancement mode. The Burst enhancement mode has a stronger buffer capacity in the output direction than the QoS enhancement mode and

can more fully use the buffer capacity of the switch, while flow control enabling in the QoS enhancement mode more depends on the buffer capacity of the upper level equipment.

- Not applicable environment:
 - Usually not recommended for the scenario with flow control deployed;

Flow control enhancement mode

This mode implements enhancement support for flow control based on factors in three aspects considered for the normal buffer mode. Since a contradictory mutual exclusion relationship exists between Burst, QoS and flow control support, the Burst buffer capacity and QoS support will be alleviated properly in flow control enhancement mode. The buffer configuration of flow control enhancement mode is characterized in that the buffer is not restricted in the input direction and the restricted value in the input direction is relatively small, enabling flow control to be triggered in the input direction to prevent packet loss of flow control before packet loss in the output direction.

- Applicable environment:
 - Environment where flow control is enabled for most ports on the equipment: Strong support to flow control can be implemented. In such an environment, packet loss will take place at the egress only when 15 ports enable 1 port at the same time, and then flow control becomes invalid.
- Not applicable environment:

Not recommended except for the environment where flow control is specially deployed for the whole equipment.

3.3.2 Configuring Buffer Monitoring

Buffer monitoring implements monitoring on the use amount of each queue and shared buffer, with a view to providing data support for network optimization and reasonable buffer configuration.

Working Principle

Buffer monitoring adopts the polling mode to read the buffer use amount of each queue and the use situation of total buffer regularly and display the buffer use situation of current equipment in real time.

↘ Port group buffer utilization alarm threshold

When the buffer utilization of port group exceeds this threshold, syslog will be printed to remind the user.

↘ Queue buffer utilization alarm threshold

When the buffer utilization of queue exceeds this threshold, syslog will be printed to remind the user.

3.3.3 Configuring Inbound Buffer Threshold Adjustment

If the inbound buffer reaches the threshold, flow control frame starts to generate on the port. If flow control is enabled, inbound flow congestion should occur and inbound buffer threshold should be reached, so that the flow control can take effect. Buffer management includes inbound buffer and outbound buffer. To make sure that inbound flow congestion occurs, the inbound buffer threshold should be less than the outbound buffer threshold.

3.3.4 Configuring Queue Counting

Queue counting monitors the forwarding and packet loss data of each queue to provide data support for network optimization and reasonable buffer configuration.

Working Principle

The queue adopts the polling mode to read the number of forwarded packets/number of bytes and the number of lost packets/number of bytes of each queue regularly, and then use the data to calculate each kind of statistics of the queue.

3.4 Configuration

Configuration	Description and Command	
Buffer Adjustment	 (Optional) It is used to configure buffer.	
	mmu queue-guarantee	Configures guaranteed buffer
	mmu queue-threshold	Configures shared buffer
	mmu buffer-mode	Configures buffer mode
Buffer Monitoring	 (Optional) It is used to configure buffer.	
	mmu usage-warn-limit	Configures the buffer utilization alarm threshold

3.4.1 Configuring Buffer Adjustment

Configuration Effect

- Configure guaranteed buffer so that the queue can share this part of buffer exclusively.
- Configure buffer mode. The queue buffer size can be configured globally.

Notes

- Configuration on the interface can be made on the physical port only.

Configuration Steps

📌 Configuring guaranteed buffer

- Optional.
- In the interface mode, use the **mmu queue-guarantee** command to configure guaranteed buffer for each queue and ensure that the buffer configuration range varies with the product.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	<code>mmu queue-guarantee output { unicast multicast } [queue-id1 [queue-id2 [queue-idN]] set value</code>
Parameter Description	<p>output: performs buffer management on the egress queue</p> <p>unicast: performs buffer management on the egress unicast queue</p> <p>multicast: performs buffer management on the egress multicast queue</p> <p><i>queue-id:</i> queue ID, in the range from 1 to 8</p> <p><i>value:</i> number of guaranteed buffers, in cells; the range depends on the product.</p>
Defaults	A fixed number of guaranteed buffers are allocated to each queue by default. The specific configuration depends on the product.
Command Mode	Interface mode
Usage Guide	The effective way of this command varies with the equipment and depends on the product.

↘ Configuring buffer mode

- Optional.
- Under the global configuration mode, use the **mmu buffer-mode** command to configure the buffer mode.

Command	<code>mmu buffer-mode { normal burst-enhance qos-enhance flowctrl-enhance }</code>
Parameter Description	<p>normal: normal buffer mode</p> <p>burst-enhance: Burst enhanced buffer mode</p> <p>qos-enhance: QoS enhanced buffer support mode</p> <p>flowctrl-enhance: flow control enhanced buffer support mode</p>
Defaults	<p>The buffer mode depends on the product positioning by default. Different products may have different default modes. The MMU mode show run is always visible.</p> <p>The terminal is relatively complicated for the access or aggregation switch, and the normal mode considers Burst, QoS and flow control in a relatively balanced way, so the default mode is the normal mode. The terminal is relatively simple for the data center switch, the low speed port is controllable, and the Burst requirement is higher, so the Burst enhancement mode is adopted by default.</p>
Command Mode	Global configuration mode
Usage Guide	The effective way of this command varies with the equipment and depends on the product.

Verification

- Use the **show running** command to check whether the MMU under the corresponding interface is configured successfully.

Configuration Examples

↘ Large buffer configuration based on egress queue

Configuration Steps	<ul style="list-style-type: none"> ● Configure the buffer mode as large buffer, i.e., Burst enhancement.
----------------------------	---

	<pre>Nodexon# configure terminal Nodexon(config)#mmu buffer-mode burst-enhance</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the created guaranteed buffer has been configured successfully.
	<pre>Nodexon# show run Buffer-mode burst-enhance</pre>

3.4.2 Configuring Buffer Monitoring

Configuration Effect

- Configure the buffer utilization alarm threshold of port group. The log alarm will be printed when the buffer utilization of port group exceeds this configured value.
- Configure the buffer utilization alarm threshold of queue. The log alarm will be printed when the buffer utilization of queue exceeds this configured value.

Notes

- Configuration on the interface can be made on the physical port only.

Configuration Steps

▾ Configuring the port group buffer utilization alarm threshold

- Optional.
- In the global configuration mode, use the **mmu usage-warn-limit** command to configure the buffer utilization alarm threshold for the port group.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu usage-warn-limit set <i>value</i>
Parameter	<i>value</i> : percentage, in the range from 1 to 100
Description	
Defaults	The default value is 0, indicating that no alarm is reported.
Command Mode	Global configuration mode
Usage Guide	This configuration takes effect for all the port groups.

▾ Configuring the queue buffer utilization alarm threshold

- Optional.
- In the interface configuration mode, use the **mmu usage-warn-limit { unicast | multicast } [queue-id1 [queue-id2 [queue-idN]] set** *value* command to configure the buffer utilization alarm threshold for each queue.

- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu usage-warn-limit { unicast multicast } [<i>queue-id1</i> [<i>queue-id2</i> [<i>queue-idN</i>]]] set <i>value</i>
Parameter Description	unicast: performs buffer management on the egress unicast queue multicast: performs buffer management on the egress multicast queue <i>queue-id:</i> queue ID, in the range from 1 to 8 <i>value:</i> percentage, in the range from 1 to 100
Defaults	The default value is 0, indicating that no alarm is reported.
Command Mode	Interface configuration mode
Usage Guide	

Verification

- Use the **show running** command to check whether the MMU under the corresponding interface is configured successfully.
- Use the **show queue-buffer** command to check whether the configuration succeeds.

Configuration Examples

Configuring the buffer utilization alarm limit based on port group

Configuration Steps	<ul style="list-style-type: none"> ● On the switch, configure the buffer utilization alarm threshold of port group as 80%. <pre>Nodexon# configure terminal Nodexon(config)# mmu usage-warn-limit set 80 Nodexon(config)#</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the created guaranteed buffer has been configured successfully. <pre>Nodexon# show run mmu usage-warn-limit set 80</pre>

Configuring the buffer utilization alarm limit based on egress queue

Configuration Steps	<ul style="list-style-type: none"> ● Configure the buffer utilization alarm threshold as 70% at the unicast queues 6 and 8 of port 1/1 on the switch. <pre>Nodexon# configure terminal Nodexon(config)# int tel/1 Nodexon(config-if)#mmu usage-warn-limit unicast 6 8 set 70</pre>
Verification	<ul style="list-style-type: none"> ● Check whether the created guaranteed buffer has been configured successfully. <pre>Nodexon#show queue-buffer interface gigabitEthernet 0/9</pre>

Dev/slot	Port-group	Total-shared (%)	Guarantee-used (%)	Share-used (%)	Available (%)	Warn-limit (%)

Multicast	4	(default)	0.0000	7.4938	NA	0.0000	NA
Multicast	5	(default)	0.0000	7.4938	NA	0.0000	NA
Multicast	6	(default)	0.0000	7.4938	NA	0.0000	NA
Multicast	7	(default)	0.0000	7.4938	NA	0.0000	NA
Multicast	8	(default)	0.0000	7.4938	NA	0.0000	NA

3.4.3 Configuring Inbound Buffer Threshold Adjustment

Configuration Effect

- Configure inbound buffer threshold of each port dynamically.

Notes

- Configuration on the interface can be made on the physical port only.

Configuration Steps

▾ Configuring guaranteed buffer

- Optional.

- In the interface mode, use the **mmu fc-threshold** command to configure inbound buffer threshold and ensure that the configuration range varies with the product.
- Use the **no** or **default** command of this command to restore the default value of buffer.

Command	mmu fc-threshold set <i>thr%</i>
Parameter Description	<i>thr%</i> : indicates a percent value. Range: 1 to 100.
Defaults	By default, each port has one inbound buffer threshold. The value varies with the product
Command Mode	Interface mode
Usage Guide	The effective way of this command varies with the equipment and depends on the product.

Verification

Use the **show running** command to check whether the MMU under the corresponding interface is configured successfully.

3.5 Monitoring

Clearing

 Running the **clear** command during operation of the equipment may lead to service interruption due to loss of important information.

Description	Command
Clears the queue counter value.	clear queue-counter
Clears the historical buffer peak.	clear queue-buffer peaked

Displaying

Description	Command
Displays the buffer use information of panel interface.	show queue-buffer interface
Displays the queue counter information of panel interface.	show queue-counter interface

Reliability Configuration

1. Configuring REUP
2. Configuring RLDP
3. Configuring DLDP
4. Configuring VRRP
5. Configuring VRRP Plus
6. Configuring BFD
7. Configuring IP Event Dampening

9. Configuring RNS

1 Configuring REUP

1.1 Overview

The Rapid Ethernet Uplink Protection Protocol (REUP) provides a rapid uplink protection function.

In the dual uplink networking, REUP is used to ensure normal communication between links, block redundant links, avoid link loops, and implement fast backup.

The upstream interfaces of REUP are configured in pairs. If both interfaces are normal, an interface works in the backup state. The interface in the backup state does not forward data packets. When the interface in the forward state is faulty, the backup interface switches to the forward state immediately, and provides data transmission. In addition, REUP also sends address update packets to upstream devices so that the upstream devices can update their MAC addresses immediately. This function of REUP ensures that layer-2 data streams can be restored within 50 ms after a link is faulty.

REUP is mutually exclusive with the Spanning Tree Protocol (STP) based on interfaces. In this case, a device runs STP downward and runs REUP upward to implement backup and fault protection for the upstream link. REUP ensures that basic link redundancy is provided when STP is disabled and that millisecond-level fault recovery faster than STP is also provided.

Protocols and Standards

- REUP is a proprietary protocol of Nodexon Network, and there is no standard and protocol for reference.

1.2 Applications

Application	Description
Communication in Dual Uplink Networking	Forward packets in the dual-uplink networking.

1.2.1 Communication in Dual Uplink Networking

Scenario

For communication in dual uplink networking, the access switch has two uplink paths, as shown in Figure 1-1.

Figure 1-1 Dual uplink networking

Deployment

- Enable REUP on interface1 and interface2 of the access switch D/E to implement fast switching when a link is faulty.
- Enable MAC address update message receiving of REUP on the interfaces connected to switches A/B/C to rapidly clear the MAC addresses on the interfaces when a link is faulty.

1.3 Features

Basic Concepts

↘ REUP Pair

Specify an interface as the backup interface of another interface to configure an REUP pair. One interface is the active interface and the other interface is the backup interface. When the two interfaces are normal, an interface is configured as the forward interface whereas the other interface is configured as the backup interface. You can determine the interface to be configured as the backup interface. See the related information in the section "Configuring the Preemption Mode and Delay Time of REUP".

↘ MAC Address Update Message

MAC address update messages refer to FLUSH packets sent by Nodexon Network to uplink devices through private multicast. When an uplink device of Nodexon Network enables the function for receiving MAC address update messages and receives MAC address update messages, the device updates the MAC addresses of corresponding interfaces.

↘ [MAC Address Update Group](#)

Multiple interfaces are added to a group. If one interface in the group receives a MAC address update message, the MAC addresses of other interfaces in the group will be updated. In this case, the group is called MAC address update group.

↘ [MAC Address Update Packet](#)

Packets sent to update MAC addresses in order to support uplink devices are called MAC address update packets.

↘ [Link Tracking Group](#)

The uplink and downstream interfaces of a device are added to a group. If all upstream interfaces in the group are down, all downstream interfaces in this group are forced down. In this case, this group is called a link tracing group.

[Overview](#)

Feature	Description
Dual Link Backup of REUP	When a link is faulty, the other link can rapidly switch to the forward state.
Preemption Mode and Delay Time of REUP	When both links are normal, the preemption mode can be used to determine the link that is used for forwarding data and the delay time that is used to determine the waiting time before switching.
MAC Address Update	During link switching, the MAC address of an interface is updated to make packet convergence faster.
VLAN Load Balance	When the two links are normal, the utilization of link bandwidth can be maximized.
Link State Tracking	When the upstream link is faulty, the downstream link is switched.

1.3.1 Dual Link Backup of REUP

When an active link is faulty, the link in the backup state will rapidly switch to the forward state and start forwarding data, minimizing the service interruption caused by link failure.

[Working Principle](#)

Specify an interface as the backup interface of another interface to configure an REUP pair. When the two interfaces are normal, a link is in the forward state (forwarding data packets) and the other link is in the backup state (not forwarding data). When the active link is faulty, the link in the backup state rapidly switches to the forward state and starts forwarding data. When the faulty link is recovered, the link enters the backup state and does not forward data packets. Of course, you can configure the preemption mode to specify whether a link recovered from failure preempts the link that is in the forward state currently.

Figure 1-2 A topology with two normal links

As shown in Figure 1-2, connect interfaces 1 and 2 of switch D (E) to the uplink switches B and C (C and B) and configure REUP on interfaces 1 and 2. When the links are normal, interface 1 is in the forward state and forwards data packets and interface 2 is in the backup state and does not forward data packets.

Figure 1-3 A topology with interface 1 of switch D (E) faulty

Once interface 1 is faulty, interface 2 immediately starts forwarding data packets and recovers the uplink transmission of the switch. In the non-preemption mode, when the link of interface 1 is recovered, interface 1 is in the backup state and does not forward data packets whereas interface 2 continues forwarding data packets.

Related Configuration

↳ Enabling Dual Link Backup on an interface

By default, dual link backup on an interface is disabled.

You can run the **switchport backup interface** command to configure a layer-2 physical interface (or layer-2 AP interface) as a backup interface and enable the dual link backup function of REUP.

You must enable the dual link backup function of REUP on an interface. The function involves the link switching of REUP only when an interface is faulty.

- ❗ REUP, ERPS, and RERP do not share interfaces.
- ❗ Devices enabled with REUP must disable the storm control function of all layer-2 interfaces.

1.3.2 Preemption Mode and Delay Time of REUP

Working Principle

You can determine which link should be used first by configuring the preemption mode of REUP. If the preemption mode is set to bandwidth first, REUP selects a link with a high bandwidth first. You can also set the preemption mode to forced to select a stable and reliable link first forcibly.

To avoid frequent active/backup link switching caused by abnormal faults, REUP provides a preemption delay function. When the two links are recovered, link switching is performed when the faulty link becomes stable after a delay (35s by default).

Related Configuration

📌 Configuring the Preemption Mode and Delay Time of REUP

By default, the preemption mode is disabled and the delay time is 35s.

You can run the **switchport backup interface preemption mode** command to configure the preemption mode.

You can run the **switchport backup interface preemption delay** command to configure the delay time.

A smaller delay means more frequent preemption switching after the faulty link is recovered.

- i** REUP uses the value of the **Bandwidth** attribute for an AP interface as the actual bandwidth of the AP interface, which is equal to the value of the **Speed** attribute (the number of link up member interfaces x the number of member interfaces).
- i** When an uplink enables STP, the preemption delay time of REUP is greater than 35s.

1.3.3 MAC Address Update

During link switching, the MAC address of an interface is updated to make packet convergence faster.

Working Principle

As shown in Figure 1-2, interface 1 and interface 2 of switch D (E) are enabled with dual link backup of REUP. Interface 1 works as the active interface. During normal communication, switch A learns the MAC addresses of users 1 and 2 (users 3 and 4) from the interfaces connecting to switch B (C).

When interface 1 of switch D (E) is faulty, interface 2 rapidly switches to the forward state and starts forwarding data packets. In this case, switch A does not learn the MAC addresses of users 1 and 2 (users 3 and 4) on the interfaces connecting to switch B (C). The data packets sent by the server to users 1 and 2 (users 3 and 4) are forwarded to switch C (B) by switch A, causing that the packets from the server to users 1 and 2 (users 3 and 4) are lost.

To avoid the preceding problems, you can enable the MAC address update function on switch D (E). When interface 2 starts forwarding packets, switch D (E) sends a MAC address update message to interface 2. After receiving the MAC address update message, switch A updates the MAC address on the interface of switch A. In this way, switch A forwards the packets sent by the server to the users to the interfaces of switch B (C) to make packet convergence faster.

In addition, import the setting of a MAC address update group, that is, classify multiple interfaces into the same group. When an interface in this group receives a MAC address update message, the MAC addresses on other interfaces in the group are updated to reduce the side effect of flooding caused by MAC address update.

To be compatible with upstream devices not supporting MAC address update messages, switch D (E) will send MAC address update packets for users 1 and 2 (users 3 and 4) upward when interface 2 switches to the forward state. In this way, switch A can update the MAC addresses of users 1 and 2 (users 3 and 4) to the corresponding interfaces and recover the downlink data transmission of switch A.

Related Configuration

▾ Enabling Sending of MAC Address Update Messages on an interface

By default, sending of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update transit** command to enable sending of MAC address updates on all interfaces of a device.

If sending of MAC address update messages is not enabled, MAC address update messages will not be sent when dual link backup switching of REUP is performed.

▾ Enabling Receiving of MAC Address Update Messages on an interface

By default, receiving of MAC address update messages is disabled on an interface.

You can run the **mac-address-table move update receive** command to enable receiving of MAC address updates on all interfaces of a device.

If receiving of MAC address update messages is not enabled, a device cannot receive MAC address update messages from downlink devices during dual link backup switching of REUP and will not update the MAC addresses.

▾ Configuring a VLAN for Sending MAC Address Update Messages

By default, a VLAN for sending MAC address update messages is the default VLAN to which an interface belongs.

You can run the **mac-address-table move update transit vlan** command to configure the VLAN in which interfaces send MAC address update messages.

If the VLAN in which interfaces send MAC address update messages is configured, the messages are sent in the configured VLAN; otherwise, the messages are sent in the default VLAN to which the interface belongs.

▾ Configuring a VLAN for Receiving MAC Address Update Messages

By default, MAC address update messages are received in all VLANs.

You can run the **no mac-address-table move update receive vlan** command to configure a VLAN in which interfaces do not receive MAC address update messages. MAC address update messages are received in remaining VLANs.

If no VLAN in which interfaces receive MAC address update messages is configured, MAC address update messages are received in all the configured VLANs; otherwise, MAC address update messages are received in the remaining VLANs.

▾ Configuring a MAC Address Update Group

By default, there is no MAC address update group.

You can run the **mac-address-table update group** command to add an interface to the MAC address update group. The interface is added to the first update group by default.

If no MAC address update group is configured, MAC address update will not be performed when MAC address update packets are received.

📌 **Configuring the Maximum Number of MAC Address Update Packets Sent Per Second**

By default, the maximum number of MAC address update packets sent per second is 150.

You can run the **mac-address-table move updatemax-update-rate** command to configure the maximum number of MAC address update packets sent per second.

The larger the number of packets, the more CPU time used for sending the packets, and the fewer downlink packets are lost.

1.3.4 VLAN Load Balance

Working Principle

The VLAN load balance function allows REUP to forward data packets of mutually exclusive VLANs for two interfaces to make full use of the link bandwidth.

As shown in Figure 1-4, configure dual link backup of REUP and enable VLAN load balance of REUP on interface 1 and interface 2 of switch D, and map VLAN 1 to instance 1 and VLAN 2 to instance 2. Data of VLAN 1 (instance 1) is transmitted through interface 1 and all the other data of VLAN 2 (instance 2) is transmitted through interface 2. Perform the same processing on switch E.

When an interface is faulty, the other interface takes over the transmission of all VLANs. When the faulty interface is recovered and does not become faulty within the preemption delay, the transmission of VLANs is switched back to the recovered interface.

Figure 1-4 A topology with two normal links of load balance

Related Configuration

▾ Enabling VLAN Load Balance on an interface

By default, the VLAN load balance function on an interface is disabled.

You can run the **switchport backup interface prefer instance** command to enable the VLAN load balance function.

If this function is not enabled, the link bandwidth cannot be fully used when packets are forwarded when the two links are normal. You must enable the VLAN load balance function on a port so that the interface can be involved in VLAN load balance.

i The instance mapping of REUP VLAN load balance is controlled by the MSTP module in a unified manner. For details about how to configure the instances, see the description in the *Configuring MSTP*.

! The VLAN load balance function can be configured only on trunk, uplink or hybrid interfaces.

1.3.5 Link State Tracking

Link tracking means that when the upstream link is faulty, services are switched to the downstream link so that the backup interface can continue forwarding packets.

Working Principle

Link state tracking provides the function of notifying downlink devices for link switching when the upstream link is faulty. You can configure the uplink and downstream interfaces of a link state tracking group and bind the link status of multiple downstream interfaces to the interfaces of multiple upstream links to implement link status synchronization. When all upstream links in a tracking group are faulty, the interfaces of the downstream links are shut down forcibly to ensure that the transmission of the downstream links is switched from the active link to the backup link.

As shown in Figure 1-5, when the upstream link of switch B is faulty, link state tracking rapidly shuts down the downstream interface of switch B so that the uplink transmission of switch D is switched to switch C.

Figure 1-5 A topology where the upstream link of the active link is faulty

Related Configuration

▾ Enabling Link Tracking

Link tracking is disabled by default.

You can run the **link state track [number]** command to enable a link tracking group. The value of **number** ranges from 1 to 2. The first link tracking group is enabled by default (the default value of **number** is 1).

If link tracking is not enabled, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

➤ **Adding an interface to a Link Tracking Group**

By default, an interface is not added to a link tracking group.

You can run the **link state group** *[number]* {**upstream** | **downstream**} command to set upstream interfaces and downstream interfaces of the link tracking group. The value of **number** ranges from 1 to 2. An interface is added to the first link tracking group by default (the default value of number is 1).

If an interface is not added to a tracking group, the status of a corresponding upstream interface cannot be detected and packet forwarding switching cannot be implemented in time.

1.4 Configuration

Configuration	Description and Command
Configuring Basic Functions of REUP	 (Mandatory) It is used to enable dual link backup of REUP.
	switchport backup interface Enables dual link backup of REUP.
Configuring the Preemption Mode and Delay Function of REUP	 (Optional) It is used to determine the preemption mode and delay time. The default values are used if they are not configured.
	switchport backup interface preemption mode Sets the preemption mode.
	switchport backup interface preemption delay Sets the delay time for preemption.
Configuring MAC Address Update	 (Optional) It is used to enable rapid update of MAC addresses.
	mac-address-table update group Sets the MAC address update group ID of a switch.
	mac-address-table move update transit Enables sending of MAC address update messages.
	mac-address-table move update transit vlan Enables sending of the VLAN ID of MAC address update messages.
	mac-address-table move update Configures the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
	mac-address-table move update receive Enables receiving of MAC address update messages.
Configuring VLAN Load Balance	mac-address-table move update receive vlan Configures the VLAN range for processing MAC address update messages.
	 (Optional) It is used to enable VLAN load balance.

Configuration	Description and Command	
	switchport backup interface prefer instance	Configures the link VLAN load balance of REUP.
Configuring Link Tracking	 (Optional) It is used to enable link tracking.	
	link state track up-delay	Enables the downlink delay up for a link state tracking group.
	link state track	Enables a link state tracking group.
	link state group	Add an interface as an upstream interface or a downstream interface of a specified link state tracking group.

1.4.1 Configuring Basic Functions of REUP

Configuration Effect

- When a link is faulty, the other normal link is switched to the forward state immediately for forwarding packets.

Notes

- An interface belongs to only one REUP pair. Each active link has only one backup link. A backup link can be used as the backup link of only one active link. The active and backup links must use different interfaces.
- REUP supports layer-2 physical interfaces and AP interfaces, but does not support AP member interfaces.
- The active and backup interfaces may be of different types and have different rates. For example, an AP interface can be used as the active interface whereas a physical interface is configured as the backup interface.
- Interfaces configured with REUP are not involved in STP calculation.
- Each device can be configured with a maximum of 16 REUP pairs.
- Interfaces successfully configured with REUP cannot change interfaces to layer-3 interfaces or be added to an AP.

Configuration Steps

↘ Enabling Dual Link Backup of REUP

- Mandatory.
- If there is no special requirement, dual link backup of REUP should be enabled on an interface of the receiving switch.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether dual link backup of REUP is configured.

Related Commands

↘ Enabling Dual Link Backup of REUP

Command	switchport backup interface <i>interface-id</i>
---------	--

Parameter Description	<i>interface-id</i> : Indicates the backup interface ID.
Command Mode	Interface configuration mode
Usage Guide	If the interface where the mode resides is the active interface, the interface corresponding to the interface-id parameter is the backup interface. When the active link is faulty, rapidly recover the transmission of the backup link.

Configuration Example

▾ Enabling Dual Link Backup of REUP

<p>Scenario</p> <p>Figure 1-6</p> <p>Dual uplink networking</p>	<p>As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure dual link backup (the interface Gi0/1 is the active interface and Gi0/2 is the backup interface) of REUP on the access switch D (E).
<p>D</p>	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>

<p>E</p>	<pre>SwitchE> enable SwitchE# configure terminal SwitchE(config)# interface GigabitEthernet 0/1 SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchE(config-if-GigabitEthernet 0/1)#switchport backup interface GigabitEthernet 0/2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Check the dual link backup information configured for switch D (E).
<p>D</p>	<pre>SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : off Preemption Delay : 35 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>

Common Errors

- Other REUP pairs are configured on a configured interface.

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.2 Configuring the Preemption Mode and Delay Function of REUP

Configuration Effect

- Restrict the preemption mode and preemption delay time for REUP link switching.

Notes

- Dual link backup of REUP must be configured.

Configuration Steps

- Optional.
- If the active link needs to always forward packets or the link bandwidth needs to be used to determine the link for forwarding packets, the corresponding preemption mode and delay time must be configured.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether the preemption mode and delay time are consistent with the configurations.

Related Commands

▾ Configuring the Preemption Mode of REUP

Command	switchport backup interface <i>interface-id</i> preemption mode {forced bandwidth off}
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	mode : Sets the preemption mode: forced : Indicates the forced mode. bandwidth : Indicates the bandwidth mode. off : Indicates that the preemption mode is off.
Command Mode	Interface configuration mode
Usage Guide	The preemption modes include forced, bandwidth and off. In the bandwidth mode, an interface with a high bandwidth is selected first to transmit data; in the forced mode, the active interface is selected first to transmit data; in the off mode, no preemption is performed. The default mode is off.

▾ Configuring the Delay Time of REUP

Command	switchport backup interface <i>interface-id</i>preemption delay <i>delay-time</i>
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	<i>delay-time</i> : Indicates the delay time.
Command Mode	Interface configuration mode

Usage Guide	Preemption delay indicates the delay time after a faulty link is recovered to the time when link switching is performed again.
--------------------	--

Configuration Example

Configuring the Preemption Mode and Delay Time of REUP

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> Configure the preemption mode to bandwidth on the access switch D (E) and the delay time to 40s.
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
E	<pre>SwitchE> enable SwitchE# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption mode bandwidth SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi 0/2 preemption delay 40 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	<ul style="list-style-type: none"> Check the dual link backup information configured for switch D (E).

	<pre>Preemption Mode : bandwidth Preemption Delay : 40 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>
E	<pre>SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Standby Interface Pair : Gi0/1, Gi0/2 Preemption Mode : bandwidth Preemption Delay : 40 seconds Bandwidth : Gi0/1(100000 Mbits), Gi0/2(100000 Mbits)</pre>

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.3 Configuring MAC Address Update

Configuration Effect

- Rapidly delete and update MAC addresses of an interface during link switching to make packet convergence faster.

Notes

- Dual link backup of REUP must be configured.
- Each device can be configured with a maximum of 8 address update groups. Each address update group can have a maximum of 8 member interfaces and an interface can belong to multiple address update groups.

Configuration Steps

- Mandatory.
- If there is no special requirement, the MAC address update function should be configured.

Verification

Run the **show mac-address-table update group [detail]** command to view the update group configuration.

Related Commands

▾ Configuring the MAC Address Update Group ID of a Switch

Command	mac-address-table update group <i>[group-num]</i>
Parameter Description	<i>group-num</i> : Indicates the MAC address update group ID.
Command Mode	Interface configuration mode
Usage Guide	In order to reduce large flooding caused by MAC address update which may affect normal data transmission of the switch, we add a setting of a MAC address update group. Only after all interfaces on a switching path are added to the same MAC address update group, transmission of downlink data can be rapidly recovered.

▾ Enabling Sending of MAC Address Update Messages

Command	mac-address-table move update transit
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	To reduce link switching and loss of downlink data streams, you need to enable sending of MAC address update messages on a switch that performs switching.

▾ Enabling Sending of the VLAN ID of MAC Address Update Messages

Command	mac-address-table move update transit vlan <i>vid</i>
Parameter Description	<i>vid</i> : Indicates the VLAN ID for sending MAC address update messages.
Command Mode	Interface configuration mode
Usage Guide	After sending of MAC address update messages is enabled, MAC address update messages can be sent to uplink devices during link switching.

Configure the maximum number of MAC address update packets sent per second.

▾ Configuring the Maximum Number of MAC Address Update Packets Sent Per Second

Command	mac-address-table move update max-update-rate <i>pkts-per-second</i>
Parameter Description	<i>pkts-per-second</i> : Indicates the maximum number of MAC address update packets sent per second. The value ranges from 0 to 32000. The default value is 150.
Command Mode	Global configuration mode
Usage Guide	During link switching, REUP sends MAC address update packets of a specified quantity to uplink devices per second to recover the downlink data transmission of the uplink device.

▾ Enabling Receiving of MAC Address Update Messages

Command	mac-address-table move update receive
----------------	--

Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	During switching of dual link backup, downlink data streams may be lost since the MAC address table of the uplink switch is not updated in real time. In order to reduce loss of layer-2 data streams, you need to update the MAC address table of the uplink switch. In this case, you need to enable receiving of MAC address update messages on the uplink switch.

▾ Configuring the VLAN Range for Processing MAC Address Update Messages

Command	mac-address-table move update receive vlan <i>vlan-range</i>
Parameter Description	<i>vlan-range</i> : Indicates the VLAN range for processing MAC address update messages.
Command Mode	Global configuration mode
Usage Guide	This command is used to disable the function for processing MAC address update messages on certain VLANs. For a VLAN disabled with the function for processing MAC address update messages, MAC address update packets can be used to recover the downlink transmission of uplink devices; however, the convergence performance for link faults will be decreased.

Configuration Example

▾ Configuring MAC Address Update

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> ● Enable sending of MAC address update messages on the access switch D (E). ● Enable receiving of MAC address update packets on switch B (C). ● Add all interfaces on the REUP switching path to the same MAC address update group. ● In the environment, Gi0/1 and Gi0/3 of switch B are the interfaces on the switching path of switch D's uplink, and Gi0/3 and Gi0/2 are the interfaces on the switching path of switch E's uplink. You can add interfaces Gi0/1, Gi0/2 and Gi0/3 to the same address update group. Similarly, you can obtain the configuration of switch C. ● Enable receiving of MAC address update packets on switch A. ● Add all interfaces on the REUP switching path of switch A to the same MAC address update group.

Gi0/1	0	0000.0000.0000	
Gi0/2	0	0000.0000.0000	

Common Errors

- A configured interface is not a layer-2 physical interface or AP interface.

1.4.4 Configuring VLAN Load Balance

Configuration Effect

- Maximize the utilization of link bandwidth.

Notes

- Dual link backup of REUP must be configured.
- The Access interface cannot be shared by VLAN load balance and STP.
- For interfaces successfully configured with VLAN load balance, you cannot modify the attributes of the interfaces but can modify the VLAN attributes of the interfaces.

Configuration Steps

- If maximizing bandwidth utilization is not required, this configuration is optional.
- If there is a requirement for VLAN load balance, corresponding configuration must be performed.

Verification

Run the **show interfaces switchport backup [detail]** command to check whether VLAN load balance is configured.

Related Commands

↘ Configuring VLAN Load Balance

Command	switchport backup interface <i>interface-id</i> prefer instance <i>instance-range</i>
Parameter	<i>interface-id</i> : Indicates the backup interface ID.
Description	<i>instance-range</i> : Indicates the load instance range of the backup interface.
Command Mode	Interface configuration mode
Usage Guide	You can modify the mapping between instances and VLANs by using the instance mapping function of MSTP.

Configuration Example

Configuring VLAN Load Balance

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
Configuration Steps	<ul style="list-style-type: none"> ● Configure instance mappings on switch D (E) to map VLAN 1 to instance 1, VLAN 2 to instance 2, VLAN 3 to instance 3, and VLAN 4 to instance 4. For details, see the <i>MSTP Configuration Guide</i>. ● Configure the VLAN load balance function on switch D (E).
D	<pre>SwitchD> enable SwitchD# configure terminal SwitchD(config)# interface GigabitEthernet 0/1 SwitchD(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi0/2 prefer instance 2 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
E	<pre>SwitchE> enable SwitchE# configure terminal SwitchE(config)# interface GigabitEthernet 0/1 SwitchE(config-if-GigabitEthernet 0/1)# switchport mode trunk SwitchD(config-if-GigabitEthernet 0/1)#switchport backup interface gi0/2 prefer instance 4 SwitchD(config-if-GigabitEthernet 0/1)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Check the dual link backup information configured for switch D (E).
D	<pre>SwitchD#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Up Instances Preferred on Active Interface: Instance 0-1,3-64 Mapping VLAN 1,3-4094</pre>

	<pre>Instances Preferred on Backup Interface: Instance 2 Mapping VLAN 2 Interface Pair : Gi0/1, Gi0/2 Preemption Mode : balance Preemption Delay : 35 seconds Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)</pre>
<p>E</p>	<pre>SwitchE#show interfaces switchport backup detail Switch Backup Interface Pairs: Active Interface Backup Interface State ----- Gi0/1 Gi0/2 Active Up/Backup Up Instances Preferred on Active Interface: Instance 0-3,5-64 Mapping VLAN 1-3,5-4094 Instances Preferred on Backup Interface: Instance 4 Mapping VLAN 4 Interface Pair : Gi0/1, Gi0/2 Preemption Mode : balance Preemption Delay : 35 seconds Bandwidth : Gi0/1(800 kbits), Gi0/2(100000 kbits)</pre>

Common Errors

- The mappings between VLAN IDs and instances are not configured.

1.4.5 Configuring Link Tracking

Configuration Effect

- After detecting that the upstream link is disconnected, forcibly disconnect the downstream link so that link switching can be performed.

Notes

- Dual link backup of REUP must be configured.
- For the link state tracking function, each interface belongs to only one link state tracking group and each device can be configured with up to 2 link state tracking groups. Each link state tracking group can have 8 upstream interfaces and 256 downstream interfaces.

Configuration Steps

- Mandatory.
- If there is no special requirement, the uplink tracking function should be configured.

Verification

Run the **show link state group** command to view the configured link tracking information.

Related Commands

▾ Enabling a Link State Tracking Group

Command	link state track [<i>num</i>]
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	
Command Mode	Global configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

▾ Adding an interface to a Link Tracking Group

Command	ink stategroup <i>num</i> { upstream downstream }
Parameter	<i>num</i> : Indicates the ID of a link state tracking group.
Description	upstream : Adds the interface as an upstream interface of the tracking group. downstream : Adds the interface as a downstream interface of the tracking group.
Command Mode	Interface configuration mode
Usage Guide	You can create a link tracking group and then add an interface to the specified tracking group.

Configuration Example

▾ Configuring a Link Tracking Group

Scenario	As shown in Figure 1-6, there are two upstream links from switch D to switch A, which are switch D > switch B > switch A and switch D > switch C > switch A. There are two upstream links from switch E to switch A, which are switch E > switch B > switch A and switch E > switch C > switch A.
-----------------	---

<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Create link tracking group 1 on switch B (C). ● On switch B (C), add the interfaces Gi0/1 and Gi0/2 as downstream interfaces of the link tracking group and add the interface Gi0/3 as an upstream interface of the link tracking group.

2 Configuring RLDP

2.1 Overview

The Rapid Link Detection Protocol (RLDP) achieves rapid detection of unidirectional link failures, directional forwarding failures and downlink loop failures of an Ethernet. When a failure is found, relevant ports will be closed automatically according to failure treatment configuration or the user will be notified to manually close the ports to avoid wrong flow forwarding or an Ethernet layer-2 loop.

2.2 Applications

Application	Description
Unidirectional Link Detection	Detect a unidirectional link failure.
Bidirectional Forwarding Detection	Detect a bidirectional link failure.
Downlink Loop Detection	Detect a link loop.

2.2.1 Unidirectional Link Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber. The two lines are the Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If any of the Tx of Port A, Rx of Port B, Tx of Port B and Rx of Port A fails, a unidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-1

Remarks	<p>A and B are layer-2 or layer-3 switches.</p> <p>The Tx of Port A of A is connected to the Rx of Port B of B.</p> <p>The Rx of Port A of A is connected to the Tx of Port B of B.</p>
----------------	---

Deployment

- Global RLDP is enabled.

- Configure unidirectional link detection under Port A and Port B and define a method for failure treatment.

2.2.2 Bidirectional Forwarding Detection

Scenario

As shown in the following figure, A is connected to B via optical fiber, and the two lines are Tx and Rx lines of optical fiber. Unidirectional link detection is enabled on A and B. If the Tx of Port A, Rx of Port B, Rx of Port A and Tx of Port B all fail, a bidirectional failure will be detected and treated under the RLDP. If the failure is eliminated, the administrator may manually restore the RLDP on A and B and resume detection.

Figure 2-2

Remarks	A and B are layer-2 or layer-3 switches. The Tx of Port A of A is connected to the Rx of Port B of B. The Rx of Port A of A is connected to the Tx of Port B of B.
----------------	--

Deployment

- Global RLDP is enabled.
- Configure BFD under Port A and Port B and define a method for failure treatment.

2.2.3 Downlink Loop Detection

Scenario

As shown in the following figure, A, B and C are connect into a loop. Downlink loop detection is enabled on A, and a loop is detected and treated.

Figure 2-3

Remarks	A, B and C are layer-2 or layer-3 switches.
----------------	---

A, B and C are interconnected via exchange ports.

Deployment

- Global RLDP is enabled on A.
- Configure downlink loop detection on the Gi 2/0/1 and Gi 2/0/9 ports of A, and define a method for failure treatment.

2.3 Features

Most Ethernet link detection mechanisms detect link connectivity through automatic physical-layer negotiation. However, in some cases devices are connected on the physical layer and operate normally but layer-2 link communication is disabled or abnormal. The RLDP recognizes a neighbor device and detects a link failure through exchanging Prob packets, Echo packets or Loop packets with the device.

Basic Concepts

↘ Unidirectional Link Failure

A unidirectional link failure occurs in case of a cross-connected optical fiber, a disconnected optical fiber, an open-circuit optical fiber, one open-circuit line in a twisted-pair cable, or unidirectional open circuit of an intermediate device between two devices. In such cases, one end of a link is connected and the other disconnected so that flow is forwarded wrongly or a loop guard protocol (for example, the STP) fails.

↘ Bidirectional Link Failure

A bidirectional link failure occurs in case of two optical fibers, two open-circuit lines in a twisted-pair cable, or bidirectional open circuit of an intermediate device between two devices. In such cases, the both ends of a link are disconnected so that flow is forwarded wrongly.

↘ Loop Failure

A downlink device is wrongly connected to form a loop, resulting in a broadcast storm.

↘ RLDP Packet

The RLDP defines three types of packets: Prob packets, Echo packets and Loop packets.

- Prob packets are layer-2 multicast packets for neighbor negotiation, and unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.
- Echo packets are layer-2 unicast packets as response to Prob packets and used for unidirectional or bidirectional link detection. The default encapsulation format is SNAP, which changes automatically to EthernetII if a neighbor sends EthernetII packets.

- Loop packets are layer-2 multicast packets for downlink loop detection. They can only be received. The default encapsulation format is SNAP.

↘ **RLDP Detection Interval and Maximum Detection Times**

A detection interval and the maximum detection times can be configured for the RLDP. A detection interval determines the period of sending Prob packets and Loop packets. When a device receives a Prob packet, it replies with an Echo packet immediately. A detection interval and the maximum detection times determine the maximum detection time (equal to a detection interval × the maximum detection times + 1) for unidirectional or bidirectional link detection. If neither Prob nor Echo packet from a neighbor can be received within the maximum detection time, the treatment of unidirectional or bidirectional failure will be triggered.

↘ **RLDP Neighbor Negotiation**

When configured with unidirectional or bidirectional link detection, a port can learn a peer-end device as its neighbor. One port may learn one neighbor, which is variable. If negotiation is enabled, unidirectional or bidirectional link detection starts after a port finds a neighbor through negotiation, which succeeds when a port receives a Prob packet from the neighbor. However, if the RLDP is enabled under a failure, the port cannot learn a neighbor so that detection cannot start. In this case, recover the link state before enabling the RLDP.

↘ **Treatment for Failed Port under RLDP**

- Warning: Only print Syslog to indicate a failed port and a failure type.
- Shutdown SVI: Print Syslog, and then inquire an SVI according to the Access VLAN or Native VLAN of a port and shut down the SVI if the port is a physical exchange port or layer-2 AP member port.
- Port violation: Print Syslog, and configure a failed port as in violation state, and the port will enter Linkdown state physically.
- Block: Print Syslog, and configure the forward state of a port as Block, and the port will not forward packets.

↘ **Recovery of Failed Port under RLDP**

- Manual reset: Manually reset all failed ports to initialized state and restart link detection.
- Manual or automatic errdisable recovery: Recover all failed ports to initialized state manually or regularly (30s by default and configurable) and restart link detection.
- Automatic recovery: Under unidirectional or bidirectional link detection, if the treatment for failed ports is not specified as port violation, recover ports to initialized state based on Prob packets and restart link detection.

↘ **Port State under RLDP**

- normal: Indicates the state of a port after link detection is enabled.
- error: Indicates the state of a port after a unidirectional or bidirectional link failure or a loop failure is detected.

↘ **Overview**

Feature	Description
Deploying RLDP Detection	Enable unidirectional or bidirectional link detection or downlink loop detection for failures and implement treatment.

2.3.1 Deploying RLDP Detection

The RLDP provides unidirectional link detection, bidirectional forwarding detection and downlink loop detection.

Working Principle

↘ Unidirectional Link Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives Prob packets but no Echo packets, or none of them, treatment for a unidirectional failure will be triggered and detection will stop.

↘ Bidirectional Forwarding Detection

When this function is enabled, a port sends Prob packets and receives Echo packets from a neighbor regularly as well as receiving Prob packets from a neighbor and replying with Echo packets. Within the maximum detection time, if the port receives neither Prob packets nor Echo packets from a neighbor, treatment for a bidirectional failure will be triggered and detection will stop.

↘ Downlink Loop Detection

When this function is enabled, a port sends Loop packets regularly. In the following cases, a loop failure will be triggered after the same port or a different port receives the packets: in one case, the egress and ingress ports are the same routed port or layer-3 AP member port; in another case, the egress and ingress ports are exchange ports or layer-2 AP member ports in a same default VLAN and in Forward state. Treatment for the failure will be implemented and detection will stop.

Related Configuration

- [Configuring RLDP Detection](#)

By default, RLDP detection is disabled.

You may run the global command **rldp enable** or the interface command **rldp port** to enable RLDP detection and specify a detection type and treatment.

You may run the **rldp neighbor-negotiation** command to neighbor negotiation, the **rldp detect-interval** to specify a detection interval, the **rldp detect-max** to specify detection times, the **rldp error-recover interval** to regularly recover the state of the failed port, or the **rldp reset** to recover a failed port.

2.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring Basic RLDP Functions	 (Mandatory) It is used to enable RLDP detection under global configuration mode.	
	rldp enable	Enables global RLDP detection on all ports.
	 (Mandatory) It is used to specify under interface configuration mode a detection type and failure treatment for an interface.	
	rldp port	Enables RLDP detection on a port and specifies a detection type and failure treatment.
	 (Optional) It is used to configure a detection interval, detection times and neighbor negotiation under global configuration mode.	
	rldp detect-interval	Modifies global RLDP parameters on all ports, such as the detection interval, maximum detection times and neighbor negotiation.
	rldp detect-max	
	rldp neighbor-negotiation	
	rldp error-recover interval	Configures the global time interval for recovering the state of the failed port.
	 (Optional) It is used under privileged mode.	
rldp reset	Recovers all ports.	

2.4.1 Configuring Basic RLDP Functions

Configuration Effect

- Enable RLDP unidirectional link detection, bidirectional forwarding detection, downlink loop detection, or VLAN-based loop detection to discover loop failures.

Notes

- Loop detection is effective to all member ports of an AP when configured on one of the ports. Unidirectional link detection and bidirectional forwarding detection are effective only on an AP member port.
- The loop detection on a physical port added to an AP shall be configured the same as that of the other member ports. There are three cases. First, if loop detection is not configured on a newly-added port but on the existing member ports, the new port adopts the configuration and detection results of the existing ports. Second, if a newly-added port and the existing member ports have different loop detection configuration, the new port adopts the configuration and detection results of the existing ports.
- When configuring the RLDP on an AP port, you may configure failure treatment only as "shutdown-port", to which other configurations will be modified.

- When "shutdown-port" is configured on a port, RLDP detection cannot be restored in case of a failure. After troubleshooting, you may run the **rldp reset** or **errdisable recovery** command to restore the port and resume detection. For configuration of the **errdisable recovery** command, please refer to the *Configuring Interface*.
- The VLAN-based loop detection function (configured by the **rldp port vlan-loop-detect** command) can be configured only on multi-VLAN ports such as trunk and hybrid ports. It is recommended not to configure this function on access or routed ports. This function does not take effect when configured on routed ports.
- It is recommended not to configure the **rldp port vlan-loop-detect** command and the **rldp port loop-detect** command on the same port. The **rldp port loop-detect** command is mainly configured on access ports to detect downlink loops.
- The VLAN list for the VLAN-based loop detection function needs to be configured in consideration of performance, and should include only VLANs that possibly encounter loops to reduce invalid detection and improve detection performance.
- The VLAN-based loop detection function can be configured only on AP member ports. It is recommended to configure the same detection VLAN on all member ports of an AP to ensure normal loop detection.

Configuration Steps

↳ Enabling RLDP

- Mandatory.
- Enable RLDP detection on all ports under global configuration mode.

↳ Enabling Neighbor Negotiation

- Optional.
- Enable the function under global configuration mode, and port detection will be started under successful neighbor negotiation.

↳ Configuring Detection Interval

- Optional.
- Configure a detection interval under global configuration mode.

↳ Configuring Maximum Detection Times

- Optional.
- Specify the maximum detection times under global configuration mode.

↳ Configuring a Time Interval for Recovering State of the Failed Port

- Optional.
- Configure the time interval for recovering the state of the failed port under global configuration mode.

↘ **Configuring Detection under Port**

- Mandatory.
- Configure unidirectional RLDP detection, bidirectional RLDP detection or downlink loop detection under interface configuration mode, and specify failure treatment.

↘ **Restoring All Failed Ports**

- Optional.
- Enable this function under privileged mode to restore all failed ports and resume detection.

Verification

- Display the information of global RLDP, port and neighbor.

Related Commands

↘ **Enabling Global RLDP Detection**

Command	<code>rldp enable</code>
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	Enable global RLDP detection.

↘ **Enabling RLDP Detection on Interface**

Command	<code>rldp port { unidirection-detect bidirection-detect loop-detect } { warning shutdown-svi shutdown-port block }</code> <code>rldp port vlan-loop-detect { warning isolate-vlan} vlan <i>vlan-list</i></code>
Parameter Description	<p>unidirection-detect: Indicates unidirectional link detection.</p> <p>bidirection-detect: Indicates bidirectional forwarding detection.</p> <p>loop-detect: Indicates downlink loop detection.</p> <p>vlan-loop-detect: Indicates VLAN-based loop detection.</p> <p>warning: Indicate the failure treatment is warning.</p> <p>shutdown-svi: Indicate the failure treatment is closing the SVI that the interface is on.</p> <p>shutdown-port: Indicates the failure treatment is port violation.</p> <p>block: Indicates the failure treatment is disabling learning and forwarding of a port.</p> <p>isolate-vlan: Indicates that the failure treatment is isolation for the faulty VLAN.</p> <p>vlan-list: Indicates the VLANs to be detected.</p>
Command	Interface configuration mode

Mode	
Usage Guide	The interfaces include layer-2 switch ports, layer-3 routed ports, layer-2 AP member ports, and layer-3 AP member ports.

↘ Modifying Global RLDP Detection Parameters

Command	rldp {detect-interval <i>interval</i> detect-max <i>num</i> neighbor-negotiation }
Parameter Description	detect-interval <i>interval</i> : Indicates a detection interval. detect-max <i>num</i> : Indicates detection times. neighbor-negotiation : Indicates neighbor negotiation.
Command Mode	Global configuration mode
Usage Guide	Modify all RLDP parameters on all ports when necessary.

↘ Recovering Failed Port

Command	rldp reset
Parameter Description	N/A
Command Mode	Privileged mode
Usage Guide	Recover all failed ports to initialized state and resume detection.

↘ Displaying RLDP State Information

Command	show rldp [interface <i>interface-name</i>]
Parameter Description	<i>interface-name</i> : Indicates the interface to display information of.
Command Mode	Privileged mode, global configuration mode, or interface configuration mode
Usage Guide	Display RLDP state information.

Configuration Example

↘ Enabling RLDP Detection in Ring Topology

Scenario Figure 2-4	As shown in the following figure, the aggregation and access sections are in a ring topology. The STP is enabled on all devices to prevent loop and provide redundancy protection. To avoid a unidirectional or bidirectional link failure resulting in STP failure, RLDP unidirectional and bidirectional link detection is enabled between aggregation devices as well as between an aggregation device and the access device. To avoid loop due to wrong downlink connection of the aggregation devices, enable RLDP downlink loop detection on the downlink ports of the aggregation devices and of the access device. To avoid loop due to wrong downlink connection of the access device, enable RLDP downlink loop detection on the downlink ports of the access device.
--------------------------------------	---

Configuration Steps

- SW A and SW B are aggregation devices, and SW C is an access device. Users connected to SW C. SW A, SW B and SW C are structured in a ring topology, and the STP is enabled on each of them. For STP configuration, refer to relevant configuration guide.
- Enable the RLDP on SW A, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable the RLDP on SW B, enable unidirectional and bidirectional link detection on the two ports, and enable loop detection on the downlink port.
- Enable the RLDP on SW C, enable unidirectional and bidirectional link detection on the two uplink ports, and enable loop detection on the two downlink ports.

A

```
A#configure terminal
A(config)#rldp enable
A(config)#interface GigabitEthernet 2/0/1
A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port
A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port
A(config-if-GigabitEthernet 2/0/1)# exit
A(config)#interface GigabitEthernet 2/0/9
A(config-if-GigabitEthernet 2/0/1)#rldp port unidirection-detect shutdown-port
A(config-if-GigabitEthernet 2/0/1)#rldp port bidirection-detect shutdown-port
A(config-if-GigabitEthernet 2/0/1)#rldp port loop-detect shutdown-port
A(config-if-GigabitEthernet 2/0/1)#exit
```

B

Apply the configuration on SW A.

C

```
C#configure terminal
C(config)#rldp enable
C(config)#interface GigabitEthernet 0/49
C(config-if-GigabitEthernet 0/49)#rldp port unidirection-detect shutdown-port
```

	<pre> C(config-if-GigabitEthernet 0/49)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/49)# exit C(config)#interface GigabitEthernet 0/50 C(config-if-GigabitEthernet 0/50)#rldp port unidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#rldp port bidirection-detect shutdown-port C(config-if-GigabitEthernet 0/50)#exit C(config)#interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/1)#exit C(config)#interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)# rldp port loop-detect shutdown-port C(config-if-GigabitEthernet 0/2)#exit </pre>
Verification	<ul style="list-style-type: none"> ● Check the RLDP information on SW A, SW B and SW C. Take SW A for example.
A	<pre> A#show rldp rldp state : enable rldp hello interval: 3 rldp max hello : 2 rldp local bridge : 00d0.f822.33aa ----- Interface GigabitEthernet 2/0/1 port state : normal neighbor bridge : 00d0.f800.51b1 neighbor port : GigabitEthernet 2/0/1 unidirection detect information: action: shutdown-port state : normal bidirection detect information: action: shutdown-port state : normal Interface GigabitEthernet 2/0/9 </pre>

```

port state      : normal

neighbor bridge : 00d0.f800.41b0

neighbor port   : GigabitEthernet 0/49

unidirection detect information:

    action: shutdown-port

    state : normal

bidirection detect information:

    action: shutdown-port

    state : normal

loop detect information:

    action: shutdown-port

    state : normal
    
```

Common Errors

- RLDP functions and private multicast address authentication or TPP are enabled at the same time.
- Neighbor negotiation is not enabled when configuring unidirectional or bidirectional link detection. The RLDP should be enabled on a neighbor device, or otherwise a unidirectional or bidirectional failure will be detected.
- If RLDP detection is configured to be implemented after neighbor negotiation while configuring unidirectional or bidirectional link detection, detection cannot be implemented as no neighbor can be learned due to a link failure. In this situation, you are suggested to recover the link state first.
- You are suggested not to specify the failure treatment as Shutdown SVI under a routed port.
- You are suggested not to specify the failure treatment as Block for a port, on which a loop protection protocol is enabled, for example, the STP.

📌 Configuring RLDP Loop Detection on Wireless APs

<p>Scenario Figure 2-5</p>	<p>As shown in the following figure, a large number of APs exist in the wireless AP scenario. If the RLDP loop detection function is configured and modified on APs one by one, the workload is heavy. The RLDP loop detection configurations can be pushed from the AC device to all online APs (or an independent AP).</p>
--	--

	
Configuration Steps	<ul style="list-style-type: none"> ● Log in to the AC device and enter the AP configuration mode. ● Enable the RLDP loop detection function on the wired ports of the corresponding AP. ● Enable the RLDP function on corresponding APs in global configuration mode. ● On corresponding APs, configure the recovery time for the RLDP violated port.
A	<pre>A#configure terminal A(config)#ap-config all A(config-ap)#exec-cmd mode "int gi 0/1" cmd "rldp port loop-detect shutdown-port" A(config-ap)#exec-cmd mode configure cmd "rldp enable" A(config-ap)#exec-cmd mode configure cmd "errdisable recovery interval 600"</pre>
Verification	<ul style="list-style-type: none"> ● On the AC device, check the RLDP loop detection configurations.
A	<pre>A# show run ! ap-config all exec-cmd mode "int gi 0/1" cmd "rldp port loop-detect shutdown-port" exec-cmd mode configure cmd "rldp enable" exec-cmd mode configure cmd "errdisable recovery interval 600" !</pre>

Common Errors

- When the **exec-cmd** command is executed for interface configuration, the input of the corresponding AP wired port is incorrect.
- When the RLDP loop detection configurations are modified, the **no exec-cmd** command is not executed to delete the original configurations or the **exec-cmd** command is not re-executed to cancel the configurations.

2.5 Monitoring

Displaying

Description	Command
Displays RLDP state.	show rldp [interface <i>interface-name</i>]

3 Configuring DLDP

3.1 Overview

The Data Link Detection Protocol (DLDP) is a protocol used to quickly detect faulty Ethernet links.

A typical Ethernet link detection mechanism detects physical link connectivity through autonegotiation at the physical layer. Such a mechanism has limitations when detecting Layer-3 data communication exceptions despite normal physical connections.

DLDP provides reliable Layer-3 link detection information. After detecting a faulty link, DLDP shuts down the logical state of Layer-3 ports to realize fast Layer-3 protocol convergence.

3.2 Applications

Application	Description
Intra-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in the same network segment.
Inter-Network Segment DLDP Detection	The source IP address of the detected port and the detected IP address are in different network segments.

3.2.1 Intra-Network Segment DLDP Detection

Scenario

This section describes the basic DLDP application scenario where the source IP address of the detected port and the detected IP address are in the same network segment.

In Figure 3-1, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/2 Layer-3 port on Switch C are in the same network segment. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/2, enable DLDP on Gi 0/1 or Gi 0/2.

Figure 3-1

Remarks	Gi 0/1 and Gi 0/2 are Layer-3 ports in the same network segment. B is a network in the same network segment as Gi 0/1 and Gi 0/2.
----------------	--

Deployment

- Enable DLDP on Gi 0/1 or Gi 0/2.

3.2.2 Inter-Network Segment DLDP Detection

Scenario

This section describes the DLDP application scenario where the source IP address of the detected port and the detected IP address are in different network segments.

In Figure 3-2, the Gi 0/1 Layer-3 port on Switch A and the Gi 0/4 Layer-3 port on Switch D are in different network segments. To detect the Layer-3 link connectivity from Gi 0/1 to Gi 0/4, enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address (IP address of the Gi 0/2 port on Switch B).

Figure 3-2

Remarks	Gi 0/1 and Gi 0/4 are Layer-3 ports in different network segments.
----------------	--

Deployment

- Enable DLDP on Gi 0/1 and configure the DLDP next-hop IP address.

3.3 Features

Basic Concepts

DLDP Detection Interval and Retransmission Times

Detection interval: Indicates the interval at which DLDP detection packets (ICMP echo) are transmitted.

Retransmission times: Indicate the maximum times DLDP detection packets can be retransmitted in the case of a DLDP detection failure.

When a network device does not receive a reply packet from the peer end within the period of the detection interval multiplied by the retransmission times, the device determines that a Layer-3 link failure occurs and shuts down the logical state of its Layer-3 port (despite the normal physical link connection). When Layer-3 link connectivity is recovered, the device restores its Layer-3 port to Up logical state.

DLDP Detection Modes

Active mode and passive mode are two DLDP detection modes.

Active mode (default): ICMP detection packets are sent actively.

Passive mode: ICMP detection packets are received passively.

DLDP Next Hop

Next hop: Indicates the next node connected to the detected IP address in inter-network segment DLDP detection.

In some cases, DLDP needs to detect IP reachability in non-directly connected network segments. You need to configure the next-hop IP address for the detected port to allow DLDP to obtain the next-hop MAC address through an ARP packet before sending a correct ICMP packet.

In this situation, you need to avoid the return of the reply packet from another link; otherwise, DLDP will misjudge that the detected port does not receive an ICMP reply.

DLDP Recovery Times

Recovery times: Indicate the times DLDP needs to receive consecutive reply packets (ICMP reply) before it can determine link failure recovery.

In some cases, link detection may be unstable. For example, a link is only intermittently pingable. In this case, DLDP repeatedly changes the link status between Up and Down, which may further destabilize the ring network.

Recovery times indicate the times DLDP needs to receive consecutive reply packets before DLDP can set the link in Down state to Up. The default recovery times are three times, indicating that the link needs to be successfully pinged three times before it is set to Up. The recovery times setting reduces link detection sensitivity but increases stability. Related parameters are adjustable according to the network condition.

DLDP Bound MAC Address

Bound MAC address: Indicates the MAC address bound to the detected IP address.

In a complex network environment, DLDP may obtain an invalid MAC address if the detected link has abnormal ARP packets transmitted (causing ARP spoofing), which will make DLDP detection abnormal.

To address this problem, you can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Overview

Feature	Description
DLDP Detection	Detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.
MAC Address Binding	Binds the detected IP address to the MAC address of the detected device to avoid DLDP exceptions otherwise caused by ARP spoofing.
Passive DLDP Detection	When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

3.3.1 DLDP Detection

DLDP detects Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the corresponding Layer-3 port.

Working Principle

After DLDP detection is enabled, DLDP sends an ARP packet to obtain the MAC address and outbound port of the detected device or the next-hop device. Then DLDP periodically sends IPv4 ICMP echo packets to the MAC address and outbound port to detect link connectivity. If DLDP does not receive an IPv4 ICMP reply packet from the detected device within a specific period, DLDP determines that the link is abnormal and sets the Layer-3 port to Down.

Related Configuration

- Enabling DLDP Detection

By default, DLDP detection is disabled on ports.

Run the **dlDP** command with the detected IP address specified to enable DLDP detection.

You can configure the next-hop IP address, MAC address of the detected device, transmission interval, retransmission times, and recovery times based on the actual environment.

3.3.2 MAC Address Binding

The MAC address binding feature is used to bind the detected IP address (or next-hop IP address) to the MAC address of the detected device (or next-hop device) to avoid DLDP exceptions otherwise caused by ARP spoofing

Working Principle

You can bind the detected IP address (or next-hop IP address) to a static MAC address to avoid a DLDP failure in the case of ARP spoofing.

Related Configuration

By default, no MAC address is bound in DLDP detection.

Bind the MAC address of the detected device when you run the **dlDP** command to enable DLDP detection. If the next-hop IP address is specified, bind the MAC address of the next-hop device.

After DLDP detection is enabled, DLDP sends ARP packets and ICMP packets with a fixed destination IP address and a fixed destination MAC address. If the source IP address and MAC address in the received packet do not match the bound IP address and MAC address, DLDP will not process the packet.

3.3.3 Passive DLDP Detection

When both ends of the detected link are enabled with DLDP, you can configure one end in passive mode to save bandwidth and CPU resources.

Working Principle

After the device at the local end sends an ICMP echo packet, the peer device determines link connectivity according to the packet reception time by using specific detection parameters, which are the same as those at the local end, thus saving bandwidth and CPU resources.

Related Configuration

By default, passive DLDP detection is disabled.

Run the **dldp passive** command to enable passive DLDP detection.

After passive DLDP detection is enabled, DLDP will return an ICMP reply packet upon receiving an ICMP echo packet, instead of actively sending ICMP echo packets to the peer end. If DLDP does not receive an ICMP echo packet within a specific period, it determines that the link to the peer port is abnormal.

3.4 Configuration

Configuration	Description and Command	
Enabling DLDP Detection	 (Mandatory) It is used to enable DLDP detection in interface configuration mode.	
	dldp Enables DLDP detection.	
	 (Mandatory) It is used to enable passive DLDP detection in interface configuration mode.	
	dldp passive Enables passive DLDP detection.	
	 (Optional) It is used to configure the detection interval, retransmission times, and recovery times of DLDP detection in global configuration mode.	
	dldp interval	Modifies the DLDP parameters globally to apply the modifications to DLDP detection on all ports.
	dldp retry	
dldp resume		

3.4.1 Enabling DLDP Detection

Configuration Effect

- Detect Layer-3 link connectivity. When a Layer-3 link is abnormal, DLDP shuts down the Layer-3 port.

Notes

- DLDP supports the configuration of multiple IP addresses on a Layer-3 port. DLDP sets the port to Down when none of the IP addresses receives an ICMP reply. If one IP address resumes communication, DLDP sets the port to Up again.
- DLDP uses the first IP address of the Layer-3 port as the source IP address of detection packets.

Configuration Steps

▾ Enabling DLDP Detection

- Mandatory.

- When you enable DLDP detection in interface configuration mode, you can configure the next-hop IP address, MAC address, transmission interval, retransmission times, and recovery times based on the actual environment.

▾ Configuring a DLDP Detection Mode

- Optional.
- You can configure active or passive DLDP detection in interface configuration mode based on the actual environment.
- If DLDP detection needs to be enabled at both ends of a Layer-3 link, you can configure passive DLDP detection at one end to save bandwidth and CPU resources.

▾ Configuring DLDP Parameters Globally

- Optional.
- You can modify the parameters of DLDP detection on all ports in global configuration mode based on requirements. The parameters include the packet transmission interval, packet retransmission times, and recovery times.

Verification

- Display the device DLDP information, including the status and statistics of DLDP detection on all ports.

Related Commands

▾ Enabling DLDP Detection

Command	dldp <i>ip-address</i> [<i>next-hop-ip</i>] [mac-address <i>mac-addr</i>] [interval <i>tick</i>] [retry <i>retry-num</i>] [resume <i>resume-num</i>]
Parameter Description	<p><i>ip-address</i>: Indicates the detected IP address.</p> <p>next-hop-ip: Indicates the next-hop IP address.</p> <p><i>mac-addr</i>: Indicates the MAC address of the detected device to be bound. If the next-hop IP address is specified, bind the MAC address of the next-hop device.</p> <p><i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s).</p> <p><i>retry-num</i>: The value ranges from 1 to 3,600. The default value is 4.</p> <p><i>resume-num</i>: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.</p>
Command Mode	Interface configuration mode
Usage Guide	The port to be enabled with DLDP detection must be a Layer-3 port, such as a router port, L3AP port, and SVI port.

▾ Configuring a DLDP Detection Mode

Command	dldp passive
Parameter Description	N/A

Command Mode	Interface configuration mode
Usage Guide	You need to enable DLDP detection before configuring a DLDP detection mode.

↘ **Modifying DLDP Detection Parameters Globally**

Command	lldp { interval tick retry retry-num resume resume-num }
Parameter Description	<p><i>tick</i>: Indicates the interval at which detection packets are transmitted. The value ranges from 5 to 6,000 ticks (1 tick = 10 ms). The default value is 100 ticks (1s).</p> <p><i>retry-num</i>: Indicates the interval at which detection packets are retransmitted. The value ranges from 5 to 3,600. The default value is 4.</p> <p><i>resume-num</i>: Indicates the recovery times. The value ranges from 1 to 200. The default value is 3.</p>
Command Mode	Global configuration mode
Usage Guide	Use this command to quickly modify the parameters of DLDP detection on all ports when the actual environment is changed.

↘ **Displaying the DLDP Status**

Command	show dldp statistic [interface interface-name]
Parameter Description	<i>interface-name</i> : Indicates the Layer-3 port on which the DLDP status will be displayed.
Command Mode	Privileged mode, global configuration mode, and interface configuration mode
Usage Guide	Use this command to display the DLDP status on a specific port. You can also use this command to display the DLDP status on all ports.

Configuration Example

↘ **Enabling DLDP Detection on Layer-3 Ports on Device A and Device B in a Layer-3 Network**

Scenario Figure 3-3	
Verification	<ul style="list-style-type: none"> Enable DLDP detection on the Gi 0/1 and Gi 0/2 router ports on Device A to detect the Layer-3 link connectivity between Device A and Device B and that between Device A and Device D.

	<ul style="list-style-type: none"> To control the Gi 0/2 router port of Device B, enable passive DLDP detection on the port. 																								
A	<pre>A#configure terminal A(config)#interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)#lldp 192.168.1.2 A(config-if-GigabitEthernet 0/1)# exit A(config)#interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/1)#lldp 192.168.3.4 192.168.2.3</pre>																								
B	<pre>B#configure terminal B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/1)#lldp 192.168.1.1 B(config-if-GigabitEthernet 0/1)#lldp passive</pre>																								
Verification	<ul style="list-style-type: none"> Display the DLDP status on Device A and Device B to check whether DLDP detection is enabled and works normally. 																								
A	<pre>A# show lldp</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Type</th> <th>Ip</th> <th>Next-hop</th> <th>Interval</th> <th>Retry</th> <th>Resume</th> <th>State</th> </tr> </thead> <tbody> <tr> <td>Gi0/1</td> <td>Active</td> <td>192.168.1.2</td> <td></td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> <tr> <td>Gi0/1</td> <td>Active</td> <td>192.168.3.4</td> <td>192.168.2.3</td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> </tbody> </table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/1	Active	192.168.1.2		100	4	3	Up	Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/1	Active	192.168.1.2		100	4	3	Up																		
Gi0/1	Active	192.168.3.4	192.168.2.3	100	4	3	Up																		
B	<pre>B# show lldp</pre> <table border="1"> <thead> <tr> <th>Interface</th> <th>Type</th> <th>Ip</th> <th>Next-hop</th> <th>Interval</th> <th>Retry</th> <th>Resume</th> <th>State</th> </tr> </thead> <tbody> <tr> <td>Gi0/2</td> <td>Passive</td> <td>192.168.1.1</td> <td></td> <td>100</td> <td>4</td> <td>3</td> <td>Up</td> </tr> </tbody> </table>	Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State	Gi0/2	Passive	192.168.1.1		100	4	3	Up								
Interface	Type	Ip	Next-hop	Interval	Retry	Resume	State																		
Gi0/2	Passive	192.168.1.1		100	4	3	Up																		

Common Errors

- An unreachable IPv4 unicast route is misjudged as a DLDP detection failure.
- DLDP detection fails because the peer device does not support ARP/ICMP replies.
- No next-hop IP address is configured in inter-network segment DLDP detection.

3.5 Monitoring

Clearing

Description	Command
-------------	---------

Clears DLDP statistics.	clear dldp [interface <i>interface-name</i> [<i>ip-address</i>]]

Displaying

Description	Command
Displays the DLDP status.	show dldp [interface <i>interface-name</i>]
Displays the DLDP statistics on the Up/Down port sates.	show dldp statistic

4 Configuring VRRP

4.1 Overview

Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol.

VRRP adopts the master-backup design to ensure migration of functions from a Master router to a Backup one when the Master failed, without influencing internal and external data communication or modifying Local Area Network (LAN) configuration. A VRRP group maps multiple routers into a virtual router. VRRP ensures only one router at a moment on behalf of a virtual router transfers packets, which is the elected Master. If the Master fails, one of the Backup routers will replace it. Under VRRP, it seems that a host in a LAN uses only one router and the routing remains functional even when the first-hop router fails.

- VRRP is applicable to LAN scenarios which require the redundancy of routing egresses.

Protocols and Standards

- RFC2338: Virtual Router Redundancy Protocol
- RFC3768: Virtual Router Redundancy Protocol (VRRP)
- RFC5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

4.2 Applications

Application	Description
Routing Redundancy	Configure routers in a LAN as one VRRP group to achieve simple routing redundancy.
Load Balancing	Configure routers in a LAN as multiple VRRP groups to achieve traffic load balancing.

4.2.1 Routing Redundancy

Scenario

Configure routers in a LAN as one VRRP group, where hosts take the virtual IP address of this group as the default gateway address.

- Packets from Host 1, Host 2 and Host 3 to other networks are forwarded by the elected Master router (Router A in Figure 4-1).
- If Router A fails, the Master will be re-elected between Router B and Router C to forward packets, achieving simple routing redundancy.

Figure 4-1

Deployment

- Router A, Router B and Router C are connected to the LAN via Ethernet interfaces.
- On Router A, Router B and Router C, VRRP is configured on the Ethernet interfaces connected to the LAN.
- These Ethernet interfaces are in the same VRRP group whose virtual IP address is 192.168.12.1.
- The gateway address for Host 1, Host 2 and Host 3 is the IP address of the VRRP group, namely 192.168.12.1.

4.2.2 Load Balancing

Scenario

Configure routers in a LAN as multiple VRRP groups. Hosts in the LAN take virtual IP addresses of the groups as their gateways, and each router backs up for other routers in different group.

- Packets from Host 1 and Host 2 to other networks with the default gateway address as the virtual IP address of virtual router 1 are forwarded by the Master of virtual router 1 (Router A in Figure 4-2).
- Packets from Host 3 and Host 4 to other networks with the default gateway address as the virtual IP address of virtual router 2 are forwarded by the Master of virtual router 2 (Router B in Figure 4-2).
- Routing redundancy is achieved on Router A and Router B, and the LAN traffic is shared to achieve load balancing.

Figure 4-2

Deployment

- Router A and Router B are connected to the LAN via Ethernet interfaces.
- On Router A and Router B, two virtual routers are configured on the Ethernet interfaces connected to the LAN.
- Router A takes the IP address 192.168.12.1 of Ethernet interface Gi0/0 as the IP address of virtual router 1. Thus for virtual router 1, Router A becomes the Master and Router B becomes the Backup.
- Router B takes the IP address 192.168.12.2 of Ethernet interface Gi0/0 as the IP address of virtual router 2. Thus for virtual router 2, Router B becomes the Master and Router A becomes the Backup.
- In the LAN, Host 1 and Host 2 take the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while Host 3 and Host 4 take the IP address 192.168.12.2 of virtual router 2 as the default gateway address.

4.3 Features

Basic Concepts

Virtual Router

A virtual router, also called a VRRP group, is regarded as a default gateway for hosts in a LAN. A VRRP group contains a Virtual Router Identifier (VRID) and a set of virtual IP addresses.

Virtual IP Address

Indicates the IP address of a virtual router. A virtual router can be configured with one or multiple IP addresses.

IP Address Owner

If a VRRP group has the virtual IP address as that of an Ethernet interface on one real router, the router is regarded as the virtual IP address owner. In such case, the router priority is 255. If the owned Ethernet interface is available, the VRRP group will be in Master state automatically. The IP address owner receives and processes the packets with the destination IP address as that of the virtual router.

Virtual MAC Address

The virtual MAC address of a VRRP group is an IEEE 802 MAC address, formatted as **00-00-5E-00-01-{VRID}** with the first five octets assigned and the last two as a group VRID. A VRRP group responds to an Address Resolution Protocol (ARP) request with its virtual MAC address instead of a real MAC address.

➤ **Master Router**

In a VRRP group, only the Master router answers ARP requests and forwards IP packets. If a real router is the IP Address Owner, it becomes the Master router.

➤ **Backup Router**

In a VRRP group, Backup routers only monitor the state of the Master but do not respond to ARP requests or forward IP packets. When the Master fails, Backup routers will take the chance to compete for the position.

➤ **Preemption Mode**

If a VRRP group runs in Preemption mode, a higher priority Backup router will replace the lower priority Master router.

Overview

Feature	Description
VRRP	VRRP achieves redundancy for the default gateways of terminals on a multi-access media (for example, Ethernet). It enables a Backup router to forward packets when the Master router is down, providing transparent routing switch and promoting network service quality.

4.3.1 VRRP

In case that the Master router is faulty, VRRP achieves migration of functions from the Master router to a Backup one without influencing internal and external data communication or modifying LAN configuration.

Working Principle

Figure 4-3 Working Principle of VRRP

➤ **Working Mode of VRRP**

The RFC2338, RFC3768 and RFC5798 protocols define the format and operating mechanism of VRRP packets. Multicast VRRP packets are sent periodically with specified destination addresses by the Master router to advertise normal operation or for Master election. VRRP allows a router in a LAN to automatically replace the Master who forwards IP packets when the latter fails. This helps achieve hot backup and fault tolerance of IP-based routing as well as ensure communication continuity and reliability for hosts in the LAN. A VRRP group achieves redundancy through multiple real routers. However, only one router acts as the Master to forward packets while the others are Backup routers. Router switching in a VRRP group is completely transparent to hosts in a LAN.

↘ Master Election Process

The RFC standards stipulate the master election process as follows:

- VRRP provides a simple mechanism for Master election. First, compare the VRRP priorities configured on the interfaces of the routers in a VRRP group. The router with the highest priority is elected as the Master. If these priorities are equal, compare the primary IP addresses of these routers. The router with the biggest IP address is elected as the Master.
- After the Master router is elected, the other routers become Backup routers (and enter the **Backup** state) and monitor the state of the master router through the VRRP packets the master router sends. If the master router is operational, it regularly sends VRRP multicast packets known as Advertisement packets to notify the Backup routers of its status. If the Backup routers do not receive such packets within a set period, all of them will enter the Master state. In such case, the previous step of Master election is repeated. In this way, a router with the highest priority will be elected as a new master, achieving VRRP backup.

Once the Master router of a VRRP group is elected, it is responsible to forward packets for hosts in a LAN.

↘ Communication Process

The VRRP communication process can be explained by Figure 1-3. The routers R1 and R2 are connected to the LAN segment 192.168.12.0/24 via the VRRP-enabled Ethernet interfaces Gi0/0. Hosts in the LAN take the virtual IP address of the VRRP group as the default gateway address. Only the virtual router is recognized by the hosts. The Master router in the group, however, is unknown. For example, when PC 1 plan to communicate with PC 2, PC 1 sends packets to the default gateway with the virtual IP address; The Master router in the group receives the packets and forwards them to PC 2. In this process, PC 1 only senses the virtual router instead of R1 or R2. The Master router in the group is elected between R1 and R2. When the Master fails, it will be replaced automatically by the other router.

Related Configuration

↘ Enabling VRRP

By default, VRRP is disabled on an interface.

In the interface configuration mode, run the `vrrp group ip ipaddress [secondary]` or `vrrp group ipv6 ipv6-address` command to set the VRID and virtual IP address to enable VRRP.

VRRP must be enabled on an interface.

↘ Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode.

Run the **vrrp group authentication *string*** command to set an authentication string in MD5 authentication mode or a plain text password in plain text mode for an IPv4 VRRP group. In the plain text authentication mode, a password contains 8 bytes at most.

Members of a VRRP group can communicate with each other only when they are in the same authentication mode. In the plain text authentication mode, all routers in a VRRP group should have the same authentication password. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations.

📌 Configuring the VRRP Advertisement Interval

By default, the advertisement interval of the Master router is 1 second.

Run the **vrrp [ipv6] group timers advertise { *advertise-interval* | **csec** *centisecond-interval* }** command to change the interval.

When VRRP learning timer is not configured, the same advertisement interval should be set for a VRRP group, otherwise routers in **Backup** state will discard received VRRP packets.

📌 Configuring the VRRP Preemption Mode

By default, a VRRP group operates in the Preemption mode.

To enable the Preemption mode for a VRRP group, run the **vrrp [ipv6] group preempt [**delay** *seconds*]** command. The optional parameter **delay** *seconds* is 0 by default.

If a VRRP group operates in the Preemption mode, a router will become the Master of the group when it finds that its priority is higher than that of the current Master. If a VRRP group operates in Non-preemption mode, a router will not become the Master even when it finds that its priority is higher than that of the current Master. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group. The optional parameter **Delay** *Seconds* defines the delay before a backup VRRP router declares its Master identity.

📌 Enabling the IPv6 VRRP Accept Mode

By default, the Accept mode is disabled for an IPv6 VRRP group.

To enable the Accept mode, run the **vrrp ipv6 group accept_mode** command.

After the Accept mode is enabled, an IPv6 VRRP virtual router in **Master** state receives and processes packets with the virtual router IP address as the destination; when the Accept mode is disabled, the virtual router discards such packets except Neighbor Advertisement (NA) packets and Neighbor Solicitation (NS) packets. Besides, an IPv6 VRRP master virtual router in **Owner** state receives and processes packets with the virtual router IP address as the destination by default no matter whether the Accept mode is configured or not.

📌 Configuring the VRRP Router Priority

By default, the router priorities in a VRRP group are all 100.

To adjust the priority, run the **vrrp [ipv6] group priority *level*** command.

If a router in the Preemption mode owns the group's virtual IP address and the highest priority, it becomes the group Master, while the other routers with lower priorities in the group become Backup (or monitoring) routers.

↘ Configuring the VRRP Tracked Interface

By default, no interface is tracked by a VRRP group.

To configure such an interface, run the **vrrp group track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* } [*priority*] or **vrrp ipv6 group track** *interface-type interface-number* [*priority*] command.

After an interface is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the interface state. Once the interface becomes unavailable, the priority of the router in the group will be reduced by a set value, and another functional and higher priority router in this group will become the Master.

↘ Configuring the VRRP Tracked IP Address

By default, no IP address is tracked by a VRRP group.

To configure such an address, run the **vrrp group track** *ip-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] or **vrrp ipv6 group track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] command.

After an IP address is configured for a VRRP group to monitor, the router priority will be adjusted dynamically based on the address accessibility. Once the address is inaccessible (the **ping** command fails), the priority of the router in the group will be reduced by a set value, and another higher priority router in this group will become the Master.

↘ Configuring the VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group.

To enable it, run the **vrrp [ipv6] group timers learn** command.

After the learning timer is configured, a VRRP Backup router learns the advertisement interval of NA packets from the Master. Based on this instead of a locally set interval, the Backup router calculates the interval for determining a failure of the Master. This command achieves the synchronization of advertisement intervals between Backup routers and the Master.

↘ Configuring the VRRP Group Description

By default, no description is configured for a VRRP group.

To configure such a string, run the **vrrp [ipv6] group description** *text* command.

A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

↘ Configuring the VRRP Delay

By default, no delay is configured for a VRRP group.

To enable it, run the **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* } command. The two types of delay range from 0 to 60 seconds.

The command configures the delay of starting a VRRP group on an interface. There are two types of VRRP delay: the delay after system startup and the delay after an interface resumes. You may configure them respectively or simultaneously. After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

📌 Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard.

To specify the version for IPv4 VRRP, run the **vrrp group version { 2 | 3 }** command.

When the parameter value is set to 2, VRRPv2 is adopted; when the parameter value is set to 3, VRRPv3 is adopted.

📌 Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

By default, IPv4 VRRP packets are sent to the first **Up** Sub VLAN interface of a Super VLAN.

To specify the first Sub VLAN in Up state of a Super VLAN to receive IPv4 VRRP packets, run the **vrrp detection-vlan first-subvlan** command; to specify a Sub VLAN, run the **vrrp detection-vlan subvlan-id** command. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN.

Both the above configurations reduce VRRP packets and avoid influencing router performance and occupying network bandwidth. Yet the routers constituting an IPv4 VRRP group should be interconnected within the first UP Sub VLAN interface or a specified Sub VLAN of the Super VLAN.

📌 Configuring the BFD Support for IPv4 VRRP on an Interface

By default, the Bidirectional Forwarding Detection (BFD) protocol support for VRRP is not enabled on an interface.

To enable it, run the **vrrp group bfd ip-address** command.

For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

After the BFD support is enabled for a specified IPv4 VRRP group, when the Master fails, a Backup router may detect it within one second.

📌 Configuring Global IPv4 VRRP BFD

By default, the VRRP does not adopt the global IPv4 VRRP BFD mode in detecting the state of the Master.

To enable global IPv4 VRRP BFD, run the **vrrp bfd interface-type interface-number ip-address** command.

After global IPv4 VRRP BFD is enabled, multiple IPv4 VRRP groups may share BFD sessions, achieving fast detection and master-backup failover.

To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.

4.4 Configuration

Configuration	Description and Command		
Configuring IPv4 VRRP	 (Mandatory) It is used to enable IPv4 VRRP.		
	<table border="1"> <tr> <td data-bbox="472 411 987 457">vrrp group ip <i>ipaddress</i> [secondary]</td> <td data-bbox="987 411 1482 457">Enables IPv4 VRRP.</td> </tr> </table>	vrrp group ip <i>ipaddress</i> [secondary]	Enables IPv4 VRRP.
	vrrp group ip <i>ipaddress</i> [secondary]	Enables IPv4 VRRP.	
	 (Optional) It is used to configure IPv4 VRRP parameters.		
	<table border="1"> <tr> <td data-bbox="472 531 987 615">vrrp group authentication <i>string</i></td> <td data-bbox="987 531 1482 615">Configures the IPv4 VRRP authentication string.</td> </tr> </table>	vrrp group authentication <i>string</i>	Configures the IPv4 VRRP authentication string.
	vrrp group authentication <i>string</i>	Configures the IPv4 VRRP authentication string.	
	<table border="1"> <tr> <td data-bbox="472 615 987 741">vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }</td> <td data-bbox="987 615 1482 741">Configures the IPv4 VRRP advertisement interval and timeout times.</td> </tr> </table>	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }	Configures the IPv4 VRRP advertisement interval and timeout times.
	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }	Configures the IPv4 VRRP advertisement interval and timeout times.	
	<table border="1"> <tr> <td data-bbox="472 741 987 825">vrrp group preempt [delay <i>seconds</i>]</td> <td data-bbox="987 741 1482 825">Configures the IPv4 VRRP Preemption mode.</td> </tr> </table>	vrrp group preempt [delay <i>seconds</i>]	Configures the IPv4 VRRP Preemption mode.
	vrrp group preempt [delay <i>seconds</i>]	Configures the IPv4 VRRP Preemption mode.	
	<table border="1"> <tr> <td data-bbox="472 825 987 867">vrrp group priority <i>level</i></td> <td data-bbox="987 825 1482 867">Configures the IPv4 VRRP router priority.</td> </tr> </table>	vrrp group priority <i>level</i>	Configures the IPv4 VRRP router priority.
	vrrp group priority <i>level</i>	Configures the IPv4 VRRP router priority.	
	<table border="1"> <tr> <td data-bbox="472 867 987 993">vrrp group track { <i>interface-type</i> <i>interface-number</i> bfd <i>interface-type</i> <i>interface-number</i> <i>ipv4-address</i> } [<i>priority</i>]</td> <td data-bbox="987 867 1482 993">Configures the IPv4 VRRP tracked interface.</td> </tr> </table>	vrrp group track { <i>interface-type</i> <i>interface-number</i> bfd <i>interface-type</i> <i>interface-number</i> <i>ipv4-address</i> } [<i>priority</i>]	Configures the IPv4 VRRP tracked interface.
	vrrp group track { <i>interface-type</i> <i>interface-number</i> bfd <i>interface-type</i> <i>interface-number</i> <i>ipv4-address</i> } [<i>priority</i>]	Configures the IPv4 VRRP tracked interface.	
	<table border="1"> <tr> <td data-bbox="472 993 987 1119">vrrp group track <i>ip-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]</td> <td data-bbox="987 993 1482 1119">Configures the IPv4 VRRP tracked IP address.</td> </tr> </table>	vrrp group track <i>ip-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]	Configures the IPv4 VRRP tracked IP address.
vrrp group track <i>ip-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]	Configures the IPv4 VRRP tracked IP address.		
<table border="1"> <tr> <td data-bbox="472 1119 987 1161">vrrp group timers learn</td> <td data-bbox="987 1119 1482 1161">Configures the IPv4 VRRP learning timer.</td> </tr> </table>	vrrp group timers learn	Configures the IPv4 VRRP learning timer.	
vrrp group timers learn	Configures the IPv4 VRRP learning timer.		
<table border="1"> <tr> <td data-bbox="472 1161 987 1245">vrrp group description <i>text</i></td> <td data-bbox="987 1161 1482 1245">Configures the IPv4 VRRP group description.</td> </tr> </table>	vrrp group description <i>text</i>	Configures the IPv4 VRRP group description.	
vrrp group description <i>text</i>	Configures the IPv4 VRRP group description.		
<table border="1"> <tr> <td data-bbox="472 1245 987 1329">vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }</td> <td data-bbox="987 1245 1482 1329">Configures the IPv4 VRRP delay.</td> </tr> </table>	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }	Configures the IPv4 VRRP delay.	
vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }	Configures the IPv4 VRRP delay.		
<table border="1"> <tr> <td data-bbox="472 1329 987 1371">vrrp group version { 2 3 }</td> <td data-bbox="987 1329 1482 1371">Configures the IPv4 VRRP version.</td> </tr> </table>	vrrp group version { 2 3 }	Configures the IPv4 VRRP version.	
vrrp group version { 2 3 }	Configures the IPv4 VRRP version.		
<table border="1"> <tr> <td data-bbox="472 1371 987 1455">vrrp detection-vlan {first-subvlan <i>subvlan-id</i>}</td> <td data-bbox="987 1371 1482 1455">Specifies a sub VLAN of a super VLAN to receive the IPv4 VRRP packets.</td> </tr> </table>	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }	Specifies a sub VLAN of a super VLAN to receive the IPv4 VRRP packets.	
vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }	Specifies a sub VLAN of a super VLAN to receive the IPv4 VRRP packets.		
<table border="1"> <tr> <td data-bbox="472 1455 987 1539">vrrp group bfd <i>ip-address</i></td> <td data-bbox="987 1455 1482 1539">Configures the BFD support for IPv4 VRRP on an Interface.</td> </tr> </table>	vrrp group bfd <i>ip-address</i>	Configures the BFD support for IPv4 VRRP on an Interface.	
vrrp group bfd <i>ip-address</i>	Configures the BFD support for IPv4 VRRP on an Interface.		
<table border="1"> <tr> <td data-bbox="472 1539 987 1623">vrrp bfd <i>interface-type</i> <i>interface-number</i> <i>ip-address</i></td> <td data-bbox="987 1539 1482 1623">Configures global IPv4 VRRP BFD.</td> </tr> </table>	vrrp bfd <i>interface-type</i> <i>interface-number</i> <i>ip-address</i>	Configures global IPv4 VRRP BFD.	
vrrp bfd <i>interface-type</i> <i>interface-number</i> <i>ip-address</i>	Configures global IPv4 VRRP BFD.		
Configuring IPv6 VRRP	 (Mandatory) It is used to enable IPv6 VRRP.		
Configuring IPv6 VRRP	<table border="1"> <tr> <td data-bbox="472 1623 987 1770">vrrp group ipv6 <i>ipv6-address</i></td> <td data-bbox="987 1623 1482 1770">Enables IPv6 VRRP in interface configuration mode.</td> </tr> </table>	vrrp group ipv6 <i>ipv6-address</i>	Enables IPv6 VRRP in interface configuration mode.
	vrrp group ipv6 <i>ipv6-address</i>	Enables IPv6 VRRP in interface configuration mode.	
 (Optional) It is used to configure IPv6 VRRP parameters.			

Configuration	Description and Command
	vrp ipv6 group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> } Configures the IPv6 advertisement interval and timeout times.
	vrp ipv6 group preempt [delay seconds] Configures the IPv6 VRRP Preemption mode.
	vrp ipv6 group accept_mode Enables the Accept mode for an IPv6 VRRP group.
	vrp ipv6 group priority level Configures the IPv6 VRRP router priority.
	vrp ipv6 group track interface-type interface-number [interface-priority] Configures the IPv6 VRRP tracked interface.
	vrp ipv6 group track { ipv6-global-address { ipv6-linklocal-address interface-type interface-number } } [interval interval-value] [timeout timeout-value] [retry retry-value] [priority] Configures the IPv6 VRRP tracked IP address.
	vrp ipv6 group timers learn Configures the IPv6 VRRP learning timer.
	vrp ipv6 group description text Configures the IPv6 VRRP group description.
	vrp delay { minimum min-seconds reload reload-seconds } Configures the IPv6 VRRP delay.
Configuring VRRP-MSTP	 The configuration is the same as IPv4 VRRP configuration.

4.4.1 Configuring IPv4 VRRP

Configuration Effect

- Configure a VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IP address.
- Configure multiple VRRP groups on an interface to achieve load balancing and offer more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv4 address.
- To achieve mutual backup between multiple IPv4 VRRP groups, configure multiple IPv4 VRRP groups with identical VRRP configuration on different interface and configure different priorities for them so that they act as the master and backup groups mutually.
- Enable VRRP on Layer-3 interfaces.

Configuration Steps

↳ Enabling IPv4 VRRP

- By default, IPv4 VRRP is disabled on an interface. You can enable it based on your demand.

↳ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in non-authentication mode. You can enable plain text authentication mode based on your demand.

↳ Configuring the IPv4 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

↳ Configuring the IPv4 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

↳ Configuring the IPv4 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

↳ Configuring the IPv4 VRRP Tracked Interface

- By default, an IPv4 VRRP group monitors no interface and the value of priority change is 10. To achieve fault monitoring through interface monitoring, please configure this item.

↳ Configuring the IPv4 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

↳ Configuring the IPv4 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

↳ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

↳ Configuring the IPv4 VRRP Version

- By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

↳ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

- By default, IPv4 VRRP packets are only sent to the first **UP** Sub VLAN interface of a Super VLAN, but you may configure a specific Sub VLAN.

↳ Configuring the BFD Support for IPv4 VRRP on an Interface

- By default, the BFD support is not configured on an interface. To configure it, use the corresponding command.

📄 Configuring Global IPv4 VRRP BFD

- By default, global IPv4 VRRP BFD is not enabled. To implement it, use the corresponding command.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

📄 Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [secondary]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipaddress</i> : Indicates the IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

📄 Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3. Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

📄 Configuring the IPv4 VRRP Advertisement Interval

Command	vrrp group timers advertise { <i>advertise-interval</i> csec centisecond-interval }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.

Command Mode	Interface configuration mode
Usage Guide	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>

↘ Configuring the IPv4 VRRP Preemption Mode

Command	vrrp group preempt [delay seconds]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p>delay seconds: Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

↘ Configuring the IPv4 VRRP Router Priority

Command	vrrp group priority level
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>level</i>: Indicates the priority of an interface in a VRRP group.</p>
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

↘ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { interface-type interface-number bfd interface-type interface-number ipv4-address } [priority]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>bfd interface-type interface-number ipv4-address: A specified adjacent IP address tracked through BFD.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface,

	<p>a Loopback interface, or a Tunnel interface).</p> <p>The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.</p>
--	--

↘ Configuring the IPv4 VRRP Tracked IP Address

Command	vrrp group track <i>ipv4-address</i> [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address to be tracked.</p> <p>interval <i>interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p>timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p>retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>To monitor a host, specify its IPv4 address for an IPv4 VRRP group.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>

↘ Configuring the IPv4 VRRP Learning Timer

Command	vrrp group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	<p>Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.</p>

↘ Configuring the IPv4 VRRP Group Description

Command	vrrp group description <i>text</i>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>text</i> : Indicates the description of a VRRP group.
Command	Interface configuration mode

Mode	
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

↘ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
Description	reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

↘ Configuring the IPv4 VRRP Version

Command	vrrp group version { 2 3 }
Parameter	2 : Indicates VRRPv2.
Description	3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

↘ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

Command	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }
Parameter	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
Description	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If VRRP and VRRP Plus are enabled simultaneously on a Super VLAN interface, VRRP packets are sent to all Up interfaces of the Sub VLANs under the Super VLAN. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

↘ Configuring the BFD Support for IPv4 VRRP on an Interface

Command	<code>vrrp group bfd ip-address</code>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Interface configuration mode
Usage Guide	<p>For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.</p> <p>If global IPv4 VRRP BFD is configured, this configuration cannot be performed.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p>

↘ Configuring Global IPv4 VRRP BFD

Command	<code>vrrp bfd interface-type interface-number ip-address</code>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Global configuration mode
Usage Guide	<p>If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p> <p>A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.</p>

Configuration Example

↘ Configuring an IPv4 VRRP Group and Tracked Interface

<p>Scenario Figure 4-4</p>	<p>The diagram illustrates a network topology with three routers (R1, R2, R3) and three workstations (A, B, C). R1 and R2 are connected to WorkStation A and C, while R3 is connected to WorkStation B. The Internet cloud is connected to all three routers. IP addresses for interfaces and workstations are provided.</p> <ul style="list-style-type: none"> R1: Gi0/0 (192.168.201.217/24), Gi2/1 (202.101.90.61/24), Gi2/1 (202.101.90.63/24), Gi0/0 (192.168.201.0/24) R2: Gi0/0 (192.168.201.213/24), Gi1/1 (60.154.101.3/24) R3: Gi0/0 (192.168.12.217/24), Gi1/1 (60.154.101.5/24), Gi2/1 (202.101.90.61/24) WorkStation A: 192.168.201.221/24 WorkStation B: 192.168.12.216/24 WorkStation C: 192.168.201.227/24
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● The cluster of Work Station A and Work Station B (192.168.201.0/24) uses the virtual IP address 192.168.201.1 of the VRRP group constituted by the routers R1 and R2 as the gateway address to communicate with Work Station B (192.168.12.0 /24). ● GigabitEthernet 2/1 on R1 is configured as the tracked interface. ● No VRRP but an ordinary routing function is configured on R3.
<p>R3</p>	<pre> R3#configure terminal R3(config)#interface GigabitEthernet 0/0 // The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 0/0)#no switchport R3(config-if-GigabitEthernet 0/0)#ip address 192.168.12.217 255.255.255.0 R3(config-if-GigabitEthernet 0/0)#exit R3(config)#interface GigabitEthernet 1/1 // The command "no switchport" is only required for a switch. R3(config-if-GigabitEthernet 1/1)#no switchport R3(config-if-GigabitEthernet 1/1)#ip address 60.154.101.5 255.255.255.0 R3(config-if-GigabitEthernet 1/1)#exit R3(config)#interface GigabitEthernet 2/1 // The command "no switchport" is only required for a switch. </pre>

	<pre>R3(config-if-GigabitEthernet 2/1)#no switchport R3(config-if-GigabitEthernet 2/1)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 2/1)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10</pre>
R1	<pre>R1#configure terminal R1(config)#interface GigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/0)#vrrp 1 priority 120 R1(config-if-GigabitEthernet 0/0)#vrrp 1 version 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R1(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/0)#vrrp 1 track GigabitEthernet 2/1 30 R1(config-if-GigabitEthernet 0/0)#exit R1(config)#interface GigabitEthernet 2/1 R1(config-if-GigabitEthernet 2/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 2/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10</pre>
R2	<pre>R2#configure terminal R2(config)#interface GigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/0)#vrrp 1 version 3 R2(config-if-GigabitEthernet 0/0)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/0)#exit R2(config)#interface GigabitEthernet 1/1 // The command “no switchport” is only required for a switch.</pre>

	<pre>R2(config-if-GigabitEthernet 1/1)#no switchport R2(config-if-GigabitEthernet 1/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 1/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10</pre>
<p>Verification</p>	<p>Run the show vrrp command to verify the configuration.</p> <ul style="list-style-type: none"> ● Check whether R1, which acts as the Master, reduces its VRRP priority from 120 to 90 when GigabitEthernet2/1 connected to the Wide Area Network (WAN) is unavailable. If yes, R2 becomes the Master. ● Check whether R1 resumes its VRRP priority from 30 to 120 when GigabitEthernet 2/1 connected to the WAN recovers. If yes, R1 is re-elected as the Master.
<p>R1</p>	<pre>R1#show vrrp GigabitEthernet 0/0 - Group 1 State is Master Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 2/1 priority decrement=30</pre>
<p>R2</p>	<pre>R2#show vrrp GigabitEthernet 0/0 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled</pre>

```

min delay is 0 sec

Priority is 100

Master Router is 192.168.201.217 , priority is 120

Master Advertisement interval is 3 sec

Master Down interval is 10.82 sec
    
```

Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

Configuration Example

Configuring Multiple IPv4 VRRP Groups

Configuration Steps	<ul style="list-style-type: none"> ● The user workstation cluster (192.168.201.0/24) uses the backup group constituted by the routers R1 and R2. The gateway for partial workstations (A for example) points to the virtual IP address 192.168.201.1 of the backup group 1, while that for other partial workstations (C for example) points to the virtual IP address 192.168.201.2 of the backup group 2. IPv4 multicast routing is enabled on all the routers. ● R1 acts as the master router in the group 2 and as a backup router in the group 1. ● R2 acts as a backup router in the group 2 and as a master router in the group 1.
R3	<pre> R3#configure terminal R3(config)#interface GigabitEthernet 0/0 // The command “no switchport” is only required for a switch. Master Down interval is 10.82 sec
```

Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

4.4.2 Configuring IPv6 VRRP

Configuration Effect

- Configure an IPv6 VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IPv6 address.
- Configure multiple IPv6 VRRP groups on an interface to achieve load balance and achieve more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor real-time failures, change interface priorities and realize master-backup failover dynamically.

Notes

- To achieve VRRP, the routers in a VRRP group should be configured with the same virtual IPv6 address.
- To achieve mutual backup for multiple IPv6 VRRP backup groups, you need to configure multiple IPv6 VRRP groups with identical VRRP configuration on an interface and configure different priorities for them to make routers master and backup mutually.
- VRRP must be enabled on Layer-3 interfaces.

Configuration Steps

▾ Enabling IPv6 VRRP in Interface Configuration Mode

- By default, IPv6 VRRP is not enabled on an interface. You can enable it based on your demand.

▾ Configuring the IPv6 VRRP Advertisement Interval

- By default, the Master router sends advertisement packets every one second. You can modify the interval based on your demand.

▾ Configuring the IPv6 VRRP Preemption Mode

- By default, a VRRP group operates in Preemption mode with a zero-second delay.

▾ Enabling the Accept Mode for an IPv6 VRRP Group

- By default, the Accept mode is disabled for an IPv6 VRRP group. To require an IPv6 VRRP VRRP group in Master state to receive and process packets with the destination IP address as that of the virtual router, enable Accept mode.

▾ Configuring the IPv6 VRRP Router Priority

- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.

▾ Configuring the IPv6 VRRP Tracked Interface

- By default, no tracked interface is configured. You can modify the interval based on your demand.

▾ Configuring the IPv6 VRRP Tracked IP Address

- By default, no tracked IPv6 address is configured and the value of priority change is 10. You can configure this function based on your demand.

▾ Configures the IPv6 VRRP Learning Timer

- By default, the learning timer is disabled for a VRRP group. Enable this function if the Backup routers need to learn the Master's advertisement interval.

↘ Configuring the IPv6 VRRP Group Description

- By default, no description is configured for a VRRP group. To distinguish VRRP groups clearly, configure descriptions.

↘ Configuring the IPv4 VRRP Delay

- By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Verification

- Run the **show ipv6 vrrp** command to verify the configuration.

Related Commands

↘ Enabling IPv6 VRRP

Command	vrrp group ipv6 <i>ipv6-address</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipv6-address</i> : Indicates the IPv6 address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	IPv6 VRRP groups and IPv4 VRRP groups share a VRID range from 1 to 255. One VRID is applicable to an IPv4 VRRP group and an IPv6 VRRP group at the same time. The first configured address should be a link-local address, which can be deleted only after other virtual addresses.

↘ Configuring the IPv6 VRRP Advertisement Interval

Command	vrrp ipv6 group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information. According to the RFC standards, if an IPv6 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.

↘ Configuring the Preemption Mode

Command	<code>vrrp ipv6 group preempt [delay seconds]</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. delay seconds : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.

▾ Enabling the Accept Mode for an IPv6 VRRP Group

Command	<code>vrrp ipv6 group accept_mode</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	By default, an IPv6 VRRP group in Master state is not permitted to receive packets with the destination IPv6 address as that of the VRRP group. However, it receives NA and NS packets no matter whether Accept mode is configured. Besides, the IP Address Owner in Master state receives and processes the packets with the destination IPv6 address as that of the VRRP group no matter whether Accept mode is configured or not.

▾ Configuring the IPv6 VRRP Router Priority

Command	<code>vrrp ipv6 group priority level</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>level</i> : Indicates the priority of a VRRP router.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

▾ Configuring the IPv6 VRRP Tracked Interface

Command	<code>vrrp ipv6 group track interface-type interface-number [priority]</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group. <i>interface-type interface-number</i> : Indicates the interface to be tracked. <i>priority</i> : Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode

Usage Guide	<p>A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface).</p> <p>The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.</p>
--------------------	--

📌 Configuring the IPv6 VRRP Tracked IP Address

Command	vrrip ipv6 group track { <i>ipv6-global-address</i> <i>ipv6-linklocal-address</i> <i>interface-type</i> <i>interface-number</i> } [interval <i>interval-value</i>] [timeout <i>timeout-value</i>] [retry <i>retry-value</i>] [<i>priority</i>]
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv6-global-address</i>: Indicates the IPv6 global unicast address.</p> <p><i>ipv6-linklocal-address</i>: Indicates the IPv6 link-local address.</p> <p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>interval <i>interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p>timeout <i>timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p>retry <i>retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for <i>retry-value</i> times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>To monitor a host, specify its IPv6 address for an IPv6 VRRP group.</p> <p>If the host IP address being tracked is a link-local address, specify a network interface.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>

📌 Configures the IPv6 VRRP Learning Timer

Command	vrrip ipv6 group timers learn
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	<p>Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.</p>

📌 Configuring the IPv6 VRRP Group Description

Command	<code>vrrp ipv6 group description text</code>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>text</i> : Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

📌 **Configuring the IPv6 VRRP Delay**

Command	<code>vrrp delay { minimum min-seconds reload reload-seconds }</code>
Parameter	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
Description	reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

Configuration Example

📌 **Configuring an IPv6 VRRP Group and Tracked Interface**

<p>Scenario Figure 4-6</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Host A and Host B access the Internet resources through the default gateway 2000::1/64. ● Nodexon A and Nodexon B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. ● Nodexon A tracks the interface GigabitEthernet 0/2 connected to the Internet. When GigabitEthernet 0/2 is unavailable, Nodexon A reduces its priority and Nodexon B acts as a gateway.
<p>NodexonA</p>	<pre>NodexonA#configure terminal</pre>

	<pre>NodexonA(config)#interface GigabitEthernet 0/1 NodexonA(config-if-GigabitEthernet 0/1)#no switchport NodexonA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64 NodexonA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 NodexonA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 track GigabitEthernet 0/2 50 NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode</pre>
NodexonB	<pre>NodexonB#configure terminal NodexonB(config)#interface GigabitEthernet 0/1 NodexonB(config-if-GigabitEthernet 0/1)#no switchport NodexonB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 NodexonB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 NodexonB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode</pre>
Verification	<p>Run the show vrrp command to verify the configuration.</p> <ul style="list-style-type: none"> ● Check whether Nodexon A, which acts as the Master router, reduces its VRRP group priority from 120 to 70 when it finds that the interface GigabitEthernet 0/2 connected to WAN is unavailable. If yes, Nodexon B becomes the Master. ● Check whether Nodexon A increases its VRRP group priority from 50 to 120 when it finds the interface GigabitEthernet 0/2 connected to WAN becomes available again. If yes, Nodexon A becomes the Master again.
NodexonA	<pre>NodexonA#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201</pre>

	<pre> Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/2 priority decrement=50 </pre>
NodexonB	<pre> NodexonB#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::1234, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec </pre>

Common Errors

- Different virtual IPv6 addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.

Configuration Example

Multiple VRRP Backup Groups (under IPv6)

Scenario
Figure 4-7

Configuration Steps

- Host A and Host B access the Internet resources through the gateways 2000::1/64 and 2000::100/64 respectively. Nodexon A and Nodexon B belong to the IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. Nodexon A and Nodexon B belong to the backup group 2 of a virtual IPv6 router, and their virtual addresses are 2000::100/64 and FE80::100 respectively. Nodexon A and Nodexon B act as gateways and forward flows, being a backup router to each other.

NodexonA

```
NodexonA#configure terminal
NodexonA(config)#interface GigabitEthernet 0/1
NodexonA(config-if-GigabitEthernet 0/1)#no switchport
NodexonA(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64
NodexonA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1
NodexonA(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode
NodexonA(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100
NodexonA(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 100
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3
NodexonA(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode
```

NodexonB	<pre> NodexonB#configure terminal NodexonB(config)#interface GigabitEthernet 0/1 NodexonB(config-if-GigabitEthernet 0/1)#no switchport NodexonB(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 NodexonB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 NodexonB(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode NodexonB(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 NodexonB(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 120 NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 </pre>
	<pre> NodexonB(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode </pre>
Verification	Run the show vrrp command to verify the configuration.
NodexonA	<pre> NodexonA#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec </pre>

	<pre>GigabitEthernet 0/1 - Group 2 State is Backup Virtual IPv6 address is as follows: FE80::100 2000::100 Virtual MAC address is 0000.5e00.0202 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::5678, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec</pre>
NodexonB	<pre>NodexonB#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::1234, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec GigabitEthernet 0/1 - Group 2 State is Master</pre>

```
Virtual IPv6 address is as follows:  
    FE80::100  
    2000::100  
Virtual MAC address is 0000.5e00.0202  
Advertisement interval is 3 sec  
Accept_Mode is enabled  
Preemption is enabled  
    min delay is 0 sec  
Priority is 120  
Master Router is FE80::5678(local), priority is 120  
Master Advertisement interval is 3 sec  
Master Down interval is 10.59 sec
```

Common Errors

- Different virtual IPv6 addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.

4.4.3 Configuring VRRP-MSTP

Configuration Effect

- Link-level and gateway-level backup are achieved and network robustness is improved greatly when MSTP and VRRP are applied simultaneously.

Notes

- configure the routers in a VRRP backup group with the same virtual IPv4 address.
- Enabled VRRP on a Layer 3 interface.

Configuration Steps

↳ Enabling IPv4 VRRP

- By default, IPv4 VRRP is not enabled on an interface. To enable IPv4 VRRP, please configure this item.

↳ Configuring the IPv4 VRRP Authentication String

- By default, VRRP is in a non-authentication mode. To enable plain text password authentication for VRRP, please configure this item.
- ↳ **Configuring the IPv4 VRRP Advertisement Interval**
- By default, a master router sends VRRP GWADV packets at an interval of one second. To manually set a value, please configure this item.
- ↳ **Configuring the IPv4 VRRP Preemption Mode**
- By default, VRRP groups work in the preemption mode with zero-second delay.
- ↳ **Configuring the IPv4 VRRP Router Priority**
- The default router priority for a VRRP group is 100. You can modify the priority based on your demand.
- ↳ **Configuring the IPv4 VRRP Tracked Interface**
- By default, an IPv4 VRRP group monitors no interface. To achieve fault monitoring through monitoring an interface, please configure this item.
- ↳ **Configuring the IPv4 VRRP Learning Timer**
- By default, timed learning is not enabled for a VRRP backup group. To enable backup routers to learn the VRRP GWADV packets from a master router, please configure this item.
- ↳ **Configuring the IPv4 VRRP Group Description**
- By default, no description is configured for a VRRP group. To distinguish VRRP groups conveniently, please configure this item.
- ↳ **Configuring the IPv4 VRRP Delay**
- By default, the VRRP delay for a VRRP group is not configured. Configure the delay to guarantee a stable transition from Non-preemption mode to Preemption mode.
- ↳ **Configuring the IPv4 VRRP Version**
- By default, the VRRPv2 standard is adopted for IPv4 VRRP packets. To modify it manually, please configure this item.
- ↳ **Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets**
- By default, IPv4 VRRP packets are only sent to the first UP Sub VLAN interface in a Super VLAN, but you may configure a specific Sub VLAN interface to send such packets.
- ↳ **Configuring the BFD Support for IPv4 VRRP on an Interface**
- By default, the linkage between an IPv4 VRRP and BFD is not configured on an interface. To enable such linkage, please configure this item.
- ↳ **Configuring Global IPv4 VRRP BFD**

- By default, global IPv4 VRRP BFD is not used to detect whether a master router is active. To enable this, please configure this item.

Verification

- Run the **show vrrp** command to verify the configuration.

Related Commands

↳ Enabling IPv4 VRRP

Command	vrrp group ip <i>ipaddress</i> [secondary]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group, the range of which varies with product models.
Description	<i>ipaddress</i> : The IP address of a VRRP group. secondary : Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

↳ Configuring the IPv4 VRRP Authentication String

Command	vrrp group authentication <i>string</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>string</i> : Indicates the authentication string of a VRRP group (a plain text password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The plain text authentication password cannot guarantee security but only prevents/prompts wrong VRRP configurations. This command is only applicable to VRRPv2 instead of VRRPv3. Authentication is abolished for VRRPv3 packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

↳ Configuring the IPv4 VRRP Advertisement Interval

Command	vrrp group timers advertise { <i>advertise-interval</i> csec <i>centisecond-interval</i> }
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>advertise-interval</i> : Indicates the advertisement interval of a VRRP group (unit: second). csec centisecond-interval : An interval for a master router in a backup group to send VRRP packets. It is an integer from 50 to 99. The unit is centisecond. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is one second.
Command Mode	Interface configuration mode

Usage Guide	<p>If a router is elected as the Master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority and other information.</p> <p>According to the RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40 seconds. Therefore, if the interval is set longer than 40 seconds, this maximum interval will be applied, though the configuration is effective.</p>
--------------------	--

↘ Configuring the IPv4 VRRP Preemption Mode

Command	vrrp group preempt [delay seconds]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	delay seconds : Indicates the preemption delay for the Master router to claim its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	<p>If a VRRP group runs in Preemption mode, a higher priority router will take the place of the lower priority Master. If a VRRP group runs in Non-preemption mode, a router with the priority higher than that of the Master remains Backup. It makes little sense to configure the Preemption mode when the VRRP group uses the IP address of an Ethernet interface, in which case the group has the highest priority and automatically becomes the Master in the group.</p>

↘ Configuring the IPv4 VRRP Router Priority

Command	vrrp group priority level
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>level</i> : Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the priority of a VRRP group.

↘ Configuring the IPv4 VRRP Tracked Interface

Command	vrrp group track { interface-type interface-number bfd interface-type interface-number ipv4-address } [priority]
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<p><i>interface-type interface-number</i>: Indicates the interface to be tracked.</p> <p>bfd interface-type interface-number ipv4-address: A specified adjacent IP address tracked through BFD.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>A tracked interface must be a routable Layer-3 logic interface (for example, a Routed port, an SVI interface, a Loopback interface, or a Tunnel interface).</p> <p>The priority of the router owns the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.</p>

▾ Configuring the IPv4 VRRP Tracked IP Address

Command	<code>vrrp group track ipv4-address [interval interval-value] [timeout timeout-value] [retry retry-value] [priority]</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>ipv4-address</i>: Indicates the IPv4 address to be tracked.</p> <p><i>interval interval-value</i>: Indicates the probe interval. The unit is second. Unless configured manually, the value is 3 seconds by default.</p> <p><i>timeout timeout-value</i>: Indicates the probe timeout of waiting for responses. If no response is received when the timeout is up, it is regarded that the destination is inaccessible. The unit is second. Unless configured manually, the value is 1 second by default.</p> <p><i>retry retry-value</i>: Indicates the probe retries. If the probe packet is sent continually for retry-value times but no response is received, it is regarded that the destination is inaccessible. The unit is times. Unless configured, the value is 3 times by default.</p> <p><i>priority</i>: Indicates the scale of VRRP priority change when the state of a monitored interface changes. The default value is 10.</p>
Command Mode	Interface configuration mode
Usage Guide	<p>To monitor a host, specify its IPv4 address for an IPv4 VRRP group.</p> <p>If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.</p>

▾ Configuring the IPv4 VRRP Learning Timer

Command	<code>vrrp group timers learn</code>
Parameter Description	<i>group</i> : Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	Once the learning timer is enabled on a VRRP router, a Backup router learns the advertisement interval of the Master during the timer. Based on this, the Backup router calculates the interval for determining the Master router as failed instead of using the locally configured advertisement interval. This command achieves synchronization with the learning timer between the Master and Backup routers.

▾ Configuring the IPv4 VRRP Group Description

Command	<code>vrrp group description text</code>
Parameter Description	<p><i>group</i>: Indicates the VRID of a VRRP group.</p> <p><i>text</i>: Indicates the description of a VRRP group.</p>
Command Mode	Interface configuration mode
Usage Guide	A VRRP description helps distinguishing VRRP groups. A description has 80 bytes at most, otherwise wrong configuration is prompted.

▾ Configuring the IPv4 VRRP Delay

Command	vrrp delay { minimum <i>min-seconds</i> reload <i>reload-seconds</i> }
Parameter	minimum <i>min-seconds</i> : Indicates the VRRP delay after an interface state changes.
Description	reload <i>reload-seconds</i> : Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group starts after the delay instead of immediately upon system startup or the interface's resumption, ensuring non-preemption. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP will be started immediately. The two types of delay share a value range of 0 to 60 seconds. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

▾ Configuring the IPv4 VRRP Version

Command	vrrp group version { 2 3 }
Parameter	2 : Indicates VRRPv2.
Description	3 : Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering the compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is developed in RFC3768, while VRRPv3 is described in RFC5798. This command is only applicable to IPv4 VRRP.

▾ Specifying a Sub VLAN of a Super VLAN to Receive the IPv4 VRRP Packets

Command	vrrp detection-vlan { first-subvlan <i>subvlan-id</i> }
Parameter	first-subvlan : Sends IPv4 VRRP packets only to the first UP Sub VLAN interface in a Super VLAN.
Description	<i>subvlan-id</i> : Sends IPv4 VRRP packets to a specified Sub VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a Sub VLAN of a Super VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a Super VLAN using the following three methods. Packets are sent to the first UP Sub VLAN interface in a Super VLAN, or to a specified Sub VLAN interface in a Super VLAN, or to all the Sub VLAN interfaces in a Super VLAN. If both VRRP and VRRP PLUS are enabled on a Super VLAN interface, VRRP packets are sent to all the UP Sub VLAN interfaces of the Super VLAN interface. This command is configured on a VLAN interface and effective only to Super VLAN interfaces.

▾ Configuring the BFD Support for IPv4 VRRP on an Interface

Command	vrrp group bfd <i>ip-address</i>
Parameter	<i>group</i> : Indicates the VRID of a VRRP group.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Interface configuration mode

Mode	
Usage Guide	<p>For a Backup router, run this command to correlate an IPv4 VRRP group with BFD without caring the configured IP address. For the Master, as the primary IP address of a Backup router is not known, the router IP address can only be specified by the administrator.</p> <p>If global IPv4 VRRP BFD is configured, this configuration cannot be performed.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p>

↘ **Configuring Global IPv4 VRRP BFD**

Command	<code>vrrp bfd interface-type interface-number ip-address</code>
Parameter	<i>interface-type interface-number</i> : Indicates interface type and ID.
Description	<i>ip-address</i> : Indicates the interface IP address.
Command Mode	Global configuration mode
Usage Guide	<p>If global IPv4 VRRP BFD is configured, the configured BFD support will be deleted.</p> <p>To enable the BFD support, make sure that IP and BFD session parameters are configured on the target interface.</p> <p>A global IPv4 VRRP BFD session is only applicable to an IPv4 VRRP group consisting of two routers.</p>

Configuration Example

↘ **Configuring VRRP+MSTP**

Scenario Figure 4-8	
Configuration Steps	<ul style="list-style-type: none"> ● Enable MSTP on routers (switches A, B, C, D, E and F in this example). Configure VLAN-Instance mapping (mapping VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0), and configure gateways (Switch A and Switch B in this example) as the root bridges of corresponding instances. ● Add the SVIs of all VLANs to corresponding VRRP backup groups, and configure gateways as the

master and backup routers for corresponding backup groups See configuration details in the following table.

Gateway	VLAN ID	SVI	Backup Group	Virtual IP Address	State
Switch A	10	192.168.10.2	VRRP 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP 30	192.168.30.1	Backup
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Configure the uplink port (port Gi 0/1 of Switch A and Switch B) of master routers as a monitored interface of master router.
- Step 1: Create VLAN. Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 respectively on Switch A and Switch B.
- Step 2: Configure MST regions. Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.
- Step 3: Configure Switch A as the root bridge for MST 0 and MST 1, and Switch B as the root bridge for MST 2.
- Step 4: Enable MSTP.
- Step 5: Configure SVIs of all the VLANs, add the SVIs to corresponding backup groups, and configure virtual IP addresses for the groups. See configuration in the above table.
- Step 6: Configure master routers and backup routers for all the groups.
- Step 7: Configure the uplink ports of master routers as monitored ports of VRRP groups. Caution: Monitored ports should be Layer 3 ports.

Step 8: Configure the Internet interfaces of the core routers as AP interfaces.

SwitchA

```
//Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 on Switch A.

SwitchA#configure terminal

Enter configuration commands, one per line. End with CNTL/Z.

SwitchA(config)#vlan range 10,20,30,40

SwitchA(config-vlan-range)#exit

//Map VLAN 10 and VLAN 20 to Instance 1, VLAN 30 and VLAN 40 to Instance 2, and the rest VLANs to Instance 0.

SwitchA(config)#spanning-tree mst configuration

Common Errors

- Different virtual IP addresses are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- Different VRRP advertisement intervals are configured on the routers in a VRRP group and the learning timer is not configured, resulting in multiple Master routers in the group.
- Different VRRP versions are configured on the routers in a VRRP group, resulting in multiple Master routers in the group.
- For VRRPv2, the Ethernet interfaces of the routers in a VRRP group are all in plain text authentication mode but inconsistent in authentication strings, resulting in multiple Master routers in the group.

4.5 Monitoring

Displaying

Description	Command
Displays the brief or detailed information of IPv4/IPv6 VRRP.	show [ipv6] vrrp [brief group]
Displays the information of an IPv4/IPv6 VRRP group on a specified interface.	show [ipv6] vrrp interface <i>type number</i> [brief]
Displays the statistics of VRRP packets.	show vrrp packet statistics [<i>interface-type interface-number</i>]

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs VRRP errors, events, packets and status.	debug [ipv6] vrrp
Debugs VRRP errors.	debug [ipv6] vrrp errors
Debugs VRRP events.	debug [ipv6] vrrp events
Debugs VRRP packets.	debug vrrp packets [acl <i>acl-id</i> [icmp protocol] interface <i>type number</i> [<i>group</i>]] debug ipv6 vrrp packets [acl <i>acl-name</i> [icmp protocol] interface <i>type number</i> [<i>group</i>]]
Debugs VRRP status.	debug [ipv6] vrrp state

5 Configuring VRRP Plus

5.1 Overview

Virtual Router Redundancy Protocol Plus (VRRP Plus) is an extension of VRRP. It uses VRRP to implement gateway backup and load balancing in the IEEE 802.3 local area network (LAN).

A disadvantage of VRRP is that the router in backup state cannot forward packets. To use VRRP to implement load balancing, you need to manually configure multiple VRRP groups and set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This increases the workload of the network administrator. VRRP Plus is designed to address this issue.

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to virtual IP addresses of different VRRP groups. This greatly reduces the workload of the network administrator.

5.2 Applications

Application	Description
Enabling Load Balancing Within a VRRP Group	Implement load balancing within a VRRP group without configuring multiple groups or configuring different default gateways for hosts.

5.2.1 Enabling Load Balancing Within a VRRP Group

Scenario

Enable load balancing within a VRRP group without configuring without configuring multiple VRRP groups or configuring different default gateways for hosts.

As shown in Figure 5-1, configure data as follows:

- Configure a VRRP group that consists of Router A and Router B, and enable the VRRP Plus function.
- Configure the default gateway of each host as the master virtual IP address of the VRRP group.

Figure 5-1 Application topology of IPv4 VRRP Plus

Remarks	<ol style="list-style-type: none"> Two layer-3 (L3) devices, Router A and Router B, form a VRRP Plus group, and the virtual IP address of the group is 192.168.12.1. Router A is the master device of VRRP and functions as a balancing virtual gateway (BVG). Router B is the backup device of VRRP and functions as a balancing virtual forwarder (BVF). Host 1 to Host 4 are hosts in the LAN with the network segment 192.168.12.0/24. Their default gateway addresses are set to the virtual IP address 192.168.12.1 of the VRRP Plus group. The load balancing policy is configured on the device to respond to the ARP requests sent from different hosts. For example, when Host 1 and Host 2 request the gateway ARP, the MAC address 0000.5e00.0101 is returned to Host 1 and Host 2. When Host 3 and Host 4 request the gateway ARP, the MAC address 001A.A916.0201 is returned to Host 3 and Host 4. In this way, packets exchanged between Host 1/Host 2 and the external network are sent to Router A, and packets exchanged between Host 3/Host 4 and the external network are sent to Router B, thereby implementing load balancing.
----------------	---

Deployment

- Deploy VRRP Plus on Router A and Router B to implement load balancing on the local host.

5.3 Features

Basic Concepts

➤ BVG

The BVG allocates virtual MAC addresses to members of the VRRP Plus group. It responds to the gateway ARP/ND requests in the LAN, and forwards packets of hosts in the LAN.

➤ BVF

The BVF forwards packets of hosts in the LAN. If a virtual MAC address is allocated to a BVF, the BVF participates in packet forwarding; otherwise, the BVF does not participate in packet forwarding.

Overview

Feature	Description
VRRP Plus	Extend VRRP and use VRRP to implement gateway backup and load balancing in the IEEE 802.3 LAN.

5.3.1 VRRP Plus

With VRRP Plus, load balancing is automatically implemented. That is, traffic of different hosts is automatically distributed to members of the VRRP Plus group, and it is unnecessary to configure multiple VRRP groups or set the gateway addresses of hosts in the LAN to the virtual IPv4/IPv6 addresses of different VRRP groups.

Basic Principles

Hosts in a LAN use the unified gateway IPv4/IPv6 address (that is, virtual IP address of the VRRP group). When different hosts request the gateway ARP/ND, the BVG responds with different virtual MAC addresses. In this way, traffic of different hosts are distributed to different members of the VRRP Plus group, thereby implementing load balancing.

Relationship Between VRRP Plus and VRRP

VRRP Plus relies on VRRP, and runs in the following way:

A master device in VRRP corresponds to a BVG in VRRP Plus, and a backup device in VRRP corresponds to a BVF in VRRP Plus. Gateway addresses of hosts in the LAN are set to the virtual IPv4/IPv6 address of VRRP.

MAC Address Allocation Rules of the BVG and BVF

The BVG allocates virtual MAC addresses to BVFs. For an IPv4 VRRP Plus group, the BVG directly uses the virtual MAC address of VRRP to ensure compatibility between IPv4 VRRP Plus and VRRP. That is, the virtual MAC address used by the BVG is 00-00-5E-00-01- $\{VRID\}$, where VRID is the VRRP group number. The virtual MAC address used by a BVF is 00-1A-A9-16- $\{MemberID\}$ - $\{VRID\}$, where MemberID is the member ID of the BVF in the VRRP Plus group. Currently, a VRRP Plus group can have up to four members. The BVG uses the member ID 01, and the other BVFs use the member IDs 02 to 04.

Load Balancing Policy of VRRP Plus

The BVG responds to the gateway ARP/NS requests sent from hosts in a LAN. Based on the specific load balancing policy, the BVG responds hosts with different virtual MAC addresses. There are three types of load balancing policies:

- Host-dependent policy: A specified virtual MAC address is used to respond to the requests sent by a specified host.
- Round-robin policy: Virtual MAC addresses in the backup group are used in a cyclic manner to respond to the gateway ARP/NS requests sent by hosts.
- Weighted policy: The ARP/NA requests are responded based on the forwarding capability of each device.

If the load balancing mode is changed, load balancing is always implemented in the new load balancing mode. For example, if the polling response mode is previously used, and later the weighted mode is used, load balancing is implemented in weighted mode regardless of the earlier responses of the device. If the weighted policy is used, and the total weight of virtual routers in a VRRP Plus group is 0, the ARP/NS requests are not responded.

▾ Proxy of the Virtual MAC Address

When a device with a virtual MAC address becomes faulty in the backup group, traffic of hosts that use this virtual MAC address as the gateway MAC address will be interrupted.

The BVG in the VRRP Plus backup group can quickly detect the fault, and automatically allocates the virtual MAC address of the faulty BVF to another device in the backup group. The new device acts as the proxy of the faulty device to forward packets of the virtual MAC address. In addition, this proxy device takes over traffic of original hosts to prevent traffic interruption. The virtual MAC address allocated to a device in the backup group can be called master virtual MAC address, and the virtual MAC address used by this device on behalf of another device is called proxy virtual MAC address.

▾ Redirection Time and Timeout of the Proxy Virtual MAC Address

VRRP Plus provides the proxy function for the virtual MAC address so that another device can take the place of a faulty device with a virtual MAC address to forward packets. If the BVF is recovered from the fault, its forwarding role is recovered and the BVF continues to forward packets of the virtual MAC address allocated to this BVF. If the faulty BVF is not recovered, the backup group stops redirecting traffic to this virtual MAC address. That is, when ARP requests are received again, this virtual MAC address is no longer responded. After a sufficient long period of time, it is believed that hosts that use the MAC address as the gateway MAC address already update the ARP/ND table entry of the gateway address, and the traffic is already taken over by other devices. At this time, this virtual MAC address can be deleted, and packets sent to this virtual MAC address are dropped.

VRRP Plus supports configuration of the redirection time and timeout of the backup group. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address and stops using this virtual MAC address for proxy forwarding. Figure 5-2 shows the changes to the role of the virtual MAC address within the redirection time and timeout.

Figure 5-2 Changes to the Role of the Virtual MAC Address Within the Redirection Time and Timeout

Weight-based Forwarding

VRRP Plus supports the weight configuration of the backup group. Different weights are configured for different devices. In this way, more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight, thereby fully utilizing the forwarding performance of different devices. When the weight of a BVF in the backup group is smaller than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is greater than the upper threshold, the BVF automatically applies for the forwarding role. The forwarding role can be recovered when one or more remaining virtual MAC addresses or proxy virtual MAC addresses exist.

Association of VRRP Plus with BFD

VRRP Plus supports association with bidirectional forwarding detection (BFD) to adjust the weight based on the link status. Each device in a backup group can associate its weight with the link status. When a link is abnormal or interrupted, the device automatically decreases its weight. When the weight is too low, the device automatically exits from the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the new weight. When the associated link recovers, the device can automatically restore its original weight and the forwarding role. If the backup group is currently using the weighted load balancing policy, traffic can be distributed based on the recovered weight. IPv6 VRRP Plus currently does not support association with BFD.

Weight-based Forwarding Seizure

VRRP Plus supports the function of seizing the forwarding role. In VRRP Plus, at most four devices can participate in load balancing. That is, a VRRP Plus backup group generates at most four virtual MAC addresses. If more than four devices are added to a VRRP Plus group, only four devices participate in packet forwarding. The remaining devices only listen to the status of other devices and do not participate in packet forwarding. Only when a device participating in packet forwarding is faulty, another device that originally does not participate in packet forwarding will take the place of the faulty device to forward packets. Assume that a VRRP Plus backup group already has four devices and all these devices participate in packet forwarding; a fifth device is added to the VRRP Plus group, and the forwarding capability of this device is strong or the original forwarding role encounters a link failure and consequently degradation of forwarding performance. In this case, if the seizure mode is enabled, the fifth device can seize the forwarding role from a device with a smaller weight (that is, with lower

forwarding capability). A greater weight is configured for a device with stronger forwarding capability. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state. This can minimize the waste of resources.

The BVG in a backup group is responsible for allocation of virtual MAC addresses. Therefore, the BVG role cannot be seized, and only the forwarding role of a BVF can be seized. If the BVG device is faulty, VRRP re-elects a new master device, which assumes the BVG role.

▾ Factors Affecting the Forwarding Policy

1. After VRRP Plus is configured, the ARP/NS requests are received from hosts can be responded based on different load balancing policies to implement load balancing among these hosts. However, load balancing cannot be implemented for hosts that have learned the VRRP virtual gateway addresses before configuration of VRRP Plus. Therefore, if VRRP Plus is configured after the VRRP state is changed to Master, real load balancing cannot be implemented before aging of the ARP/NDs learned by hosts. Load balancing is implemented only after the gateway ARP/NDs recorded by the hosts age and the hosts request for new gateway addresses.
2. Periodical sending of gratuitous ARPs on an interface also affect the load balancing function of VRRP Plus. When VRRP Plus is enabled, the function of sending gratuitous ARPs of VRRP virtual IP addresses will be disabled. When an virtual IP address overlaps with an actual IP address, gratuitous ARPs of this address are no longer sent.
3. When an address conflict occurs between a host and the local device, the ARP/NA module will broadcast gratuitous ARP/NA packets of this address. If a conflict of the VRRP Plus virtual address occurs, sending gratuitous ARP/NA packet will result re-learning of the host's gateway MAC address, which negatively affects the load balancing function of VRRP Plus. Therefore, the load balancing function of VRRP Plus is currently not supported in this scenario.

5.4 Configuration

Configuration Item	Description and Command	
Configuring VRRP Plus	 (Mandatory) It is used to enable the VRRP Plus function.	
	vrrp balance	Enables the VRRP Plus function of a VRRP backup group with the specified group ID in interface configuration mode.
	 (Optional) It is used to configure parameters of a VRRP Plus backup group.	
	vrrp load-balancing	Configures the load balancing policy of VRRP Plus in interface configuration mode.
	vrrp timers redirect	Configures the redirection time and timeout of the proxy virtual MAC address in a VRRP Plus backup group in interface configuration mode.
	vrrp weighting	Configures the weight and upper and lower thresholds of a VRRP Plus backup group in interface configuration mode.

Configuration Item	Description and Command	
	<code>vrrp forwarder preempt</code>	Configures the forwarding seizure function of a VRRP Plus backup group in interface configuration mode.

5.4.1 Configure VRRP Plus

Configuration Effect

- Enable the VRRP Plus function. (By default, this function is disabled.)
- Configure a weight tracking object of a VRRP Plus backup group.

Notes

- To enable the VRRP Plus function, you must configure the VRRP virtual IP address for the corresponding backup group.

Configuration Steps

▾ Enabling VRRP Plus on an Interface

- By default, VRRP Plus is enabled. Perform this configuration if VRRP Plus is required.

▾ Configuring the Load Balancing Policy of VRRP Plus

- After VRRP Plus is enabled, the host-dependent load balancing policy is used by default.

▾ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

- After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default.

▾ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the weight of the backup group is set to 100, the lower threshold to 1, and the upper threshold to 100 by default.

▾ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

- After VRRP Plus is enabled, the forwarding seizure function is enabled by default.

▾ Configuring the Weight Tracking Object of a VRRP Plus Backup Group

- The weight tracking object of a VRRP Plus backup group is disabled by default. Perform this configuration if the tracking function is required.

Verification

- Run the `show group vrrp balance` command to display the VRRP backup group configuration. If the backup group has the packet forwarding tasks, "local" is displayed in the **forwarders** column, and the virtual MAC address allocated to this backup group is also displayed.

Related Commands

▾ Enabling VRRP Plus on an Interface

Command	<code>vrrp group balance</code>
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. The value range of the group ID varies according to the product model.
Command Mode	Interface configuration mode
Usage Guide	VRRP Plus can be enabled only after a VRRP group is configured.

▾ Configuring the Load Balancing Policy of a VRRP Plus Backup Group

Command	<code>vrrp group load-balancing{host-dependent round-robin weighted }</code>
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. host-dependent : Indicates the host-dependent load balancing policy. round-robin : Indicates the round-robin load balancing policy. weighted : Indicates the weighted load balancing policy.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the host-dependent load balancing policy is used by default. The load balancing policy of the entire backup group is determined by the policy configured on the BVG. If you wish to use the same load balancing policy after the role of the BVG device changes, configure the same policy on all devices in the backup group.

▾ Configuring the Redirection Time and Timeout of the Proxy Virtual MAC Address in a VRRP Plus Backup Group

Command	<code>vrrp group timers redirect redirect timeout</code>
Parameter Description	<i>group</i> : Indicates the ID of the VRRP group. <i>redirect</i> : Indicates the redirection time. The value ranges from 0 to 3,600s. The default value is 300s, that is, 5 minutes. <i>timeout</i> : Indicates the timeout time. The value ranges from (redirect + 600) to 64,800s. The default value is 14400, that is, 4 hours.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the redirection time is set to 300s and timeout is set to 14,400s by default. When a device is faulty, the backup group allocates the virtual MAC address of the faulty device to another device. Within the redirection time, the backup group continues to use this virtual MAC address to respond the ARP/NS requests. When the redirection time expires, the backup group no longer uses this virtual MAC address to respond the requests. When the timeout elapses, the backup group deletes this virtual MAC address.

▾ Configuring the Weight and Upper and Lower Thresholds of a VRRP Plus Backup Group

Command	vrrp group weighting maximum [lower lower] [upper upper]
Parameter Description	<p>maximum: Indicates the weight of the backup group. The value ranges from 2 to 254. The default value is 100.</p> <p>lower lower: Indicates the lower threshold of the backup group. The value ranges from 1 to (maximum - 1). The default value is 1.</p> <p>upper upper: Indicates the upper threshold of the backup group. The value ranges from lower to maximum. The default value is 100.</p>
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the weight and upper and lower thresholds of a VRRP Plus backup group are configured by default. You can use this command to configure different weights for different devices so that more traffic is distributed to the device with a greater weight and less traffic is distributed to the device with a smaller weight. When the weight of a BVF in the backup group is lower than the lower threshold, the BVF automatically exits from the forwarding role. When the weight recovers and is higher than the upper threshold, the forwarding role of the BVF is automatically restored.

↘ Configuring the Forwarding Seizure Function of a VRRP Plus Backup Group

Command	vrrp group forwarder preempt
Parameter Description	group: Indicates the ID of the VRRP group.
Command Mode	Interface configuration mode
Usage Guide	After VRRP Plus is enabled, the forwarding seizure function is enabled by default. VRRP Plus supports configuration of the forwarding seizure function of a backup group. When the weight of a device in listening state is found greater than that of a forwarding device, the device in listening state automatically seizes the forwarding role from the forwarding device. That is, the device with stronger forwarding capability forwards packets, whereas the device with lower forwarding capability is in listening state.

Configuration Example

↘ Enabling Load Balancing Within an IPv4 VRRP Group

<p>Scenario</p> <p>Figure 5-3</p>	<p>The diagram illustrates a VRRP Plus configuration. Two routers, Router A (BVG) and Router B (BVF), are connected to an Internet cloud. Router A has a physical interface Gi 0/14 and a virtual interface Gi 0/0 with IP 192.168.12.3 and virtual MAC vmac1. Router B has a physical interface Gi 0/14 and a virtual interface Gi 0/0 with IP 192.168.12.2 and virtual MAC vmac2. Both routers are connected to a LAN interface labeled '192.168.12.0/24'. The LAN contains four hosts (Host 1, Host 2, Host 3, Host 4) connected to a shared interface. Hosts 1 and 2 have a gateway MAC of vmac1, while Hosts 3 and 4 have a gateway MAC of vmac2. The LAN default gateway is 192.168.12.1.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a VRRP group and enable VRRP Plus respectively on Router A and Router B. Configure the local IP addresses so that Router A becomes a BVG (master) device, and Router B becomes a BVF (backup) device. ● Configure the weighted load balancing policy. Configure the weight tracking object, and set the decrement value to 100. ● Retain default configurations of the weight, upper and lower thresholds, redirection time, timeout, and forwarding seizure of the backup group. ● Set the default gateway addresses of Host 1 to Host 4 in the LAN to the virtual IP address of VRRP, that is, 192.168.12.1.
<p>Router A</p>	<pre>NodexonA#config NodexonA(config)#interface GigabitEthernet0/0 // 'no switchport' is used on the switch. NodexonA(config-if-GigabitEthernet 0/0)#no switchport NodexonA(config-if-GigabitEthernet 0/0)#ip address 192.168.12.3 255.255.255.0 NodexonA(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1 NodexonA(config-if-GigabitEthernet 0/0)#vrrp 1 balance NodexonA(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted</pre>
<p>Router B</p>	<pre>NodexonB#config NodexonB(config)#interface GigabitEthernet0/0 NodexonB(config-if-GigabitEthernet 0/0)#no switchport NodexonB(config-if-GigabitEthernet 0/0)#ip address 192.168.12.2 255.255.255.0 NodexonB(config-if-GigabitEthernet 0/0)#vrrp 1 ip 192.168.12.1</pre>

	<pre>NodexonB(config-if-GigabitEthernet 0/0)#vrrp 1 balance NodexonB(config-if-GigabitEthernet 0/0)#vrrp 1 load-balancing weighted</pre>
<p>Verification</p>	<p>Run the show vrrp balance command to display the configuration of the VRRP Plus group. If the backup group has the packet forwarding tasks, "local" is displayed in the forwarders column, and the virtual MAC address allocated to this backup group is also displayed.</p>
<p>Router A</p>	<pre>NodexonA# show vrrp balance interface GigabitEthernet0/0 State is BVG Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 There are 2 forwarders Forwarder 1 (local) MAC address: 0000.5e00.0101 Owner ID is 0000.0001.0006 Preemption disabled (BVG cannot be preempted) Forwarder 2 MAC address: 001a.a916.0201 Owner ID is 00d0.f822.33a3 Preemption enabled</pre>
<p>Router B</p>	<pre>NodexonB# show vrrp balance interface GigabitEthernet0/0 State is BVF Virtual IP address is 192.168.12.1 Hello time 1 sec, hold time 3 sec Load balancing: weighted Redirect time 300 sec, forwarder time-out 14400 sec Weighting 100 (configured 100), thresholds: lower 1, upper 100 There are 2 forwarders</pre>

```

Forwarder 1
  MAC address:
    0000.5e00.0101
  Owner ID is 0000.0001.0006
  Preemption disabled (BVG cannot be preempted)
Forwarder 2 (local)
  MAC address:
    001a.a916.0201
  Owner ID is 00d0.f822.33a3
  Preemption enabled
    
```

Common Errors

- VRRP Plus does not take effect because the VRRP virtual IP address is not configured for the related group.

5.5 Monitoring

Displaying

Description	Command
Displays the brief or detailed configuration of VRRP Plus.	show vrrp balance
Displays the actions of the VRRP Plus group on a specified interface.	show vrrp balance interface

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the VRRP Plus function.	debug vrrp balance
Debugs errors.	debug vrrp balance error
Debugs events of the VRRP Plus group.	debug vrrp balance event
Debugs the messages between the VRRP module and the track module.	debug vrrp balance messages
Debugs the VRRP Plus packets.	Debug vrrp balance packets
Debugs the VRRP Plus group status.	debug vrrp balance state
Debugs the timers of the VRRP Plus group.	debug vrrp balance timer

6 Configuring BFD

6.1 Overview

Communication failures will interrupt networking and thus affect services. Therefore, it is essential to rapidly locate communication failures on links with adjacent devices to ensure a timely action and service availability. Bidirectional Forwarding Detection (BFD) provides a method of rapidly detecting connectivity of the forwarding path between two adjacent routers in an underloaded way. It can quickly spot faults on the bidirectional forwarding path between two routers for upper-layer protocols such as routing protocols and Multi-Protocol Label Switching (MPLS). As a result, a standby forwarding path is adopted to maintain the performance of the existing network.

Protocols and Standards

- draft-ietf-bfd-base-09: Bidirectional Forwarding Detection
- draft-ietf-bfd-generic-05: Generic Application of BFD
- draft-ietf-bfd-mib-06: Bidirectional Forwarding Detection Management Information Base
- draft-ietf-bfd-v4v6-1hop-09: BFD for IPv4 and IPv6 (Single Hop)
- draft-ietf-bfd-multihop-07: BFD for IPv4 and IPv6 (Multi-hop)
- draft-ietf-bfd-mpls-07: BFD For MPLS LSPs

✔ Currently, draft-ietf-bfd-mib-06 and draft-ietf-bfd-multihop-07 are not supported.

6.2 Applications

Application	Description
BFD Support for OSPF	OSPF utilizes BFD to rapidly detect the neighbor status.
BFD Support for Static Routing	Static routing utilizes BFD to rapidly detect the next-hop reachability of a route.

6.2.1 BFD Support for OSPF

Scenario

The Open Shortest Path First (OSPF) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, a BFD session is established with the neighbor in the full adjacency to detect the neighbor status. When the neighbor fails, OSPF immediately performs network convergence. The convergence time can be shortened from 120 seconds (by default, on a non-broadcast network, OSPF hello packets are transmitted at an interval of 30 seconds and the neighbor failure time is four times the interval, that is, 120 seconds) to 1 second.

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, OSPF is configured on the routers to establish routes, and BFD support for OSPF is enabled on the interfaces of Router A and Router B. When

the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to OSPF, so as to trigger fast OSPF convergence.

Figure 6-1

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.
----------------	--

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Run OSPF on Router A and Router B.
- Set BFD parameters on interconnected interfaces of Router A and Router B.
- Enable BFD support for OSPF on Router A and Router B.

6.2.2 BFD Support for Static Routing

Scenario

BFD support for static routing prevents routers from selecting a faulty static route as the forwarding path and enables rapid routing failover by using an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the neighbor discovery (ND) mechanism. When BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session status. If a BFD session fails, the next hop of a static route is thought unreachable and will not be added to the routing information base (RIB).

Use the following figure as an example. Router A and Router B are connected through a Layer-2 switch, static routing is configured on the routers to establish forwarding paths, and BFD support for static routing is enabled on the interfaces of Router A and Router B. When the link between Router B and the Layer-2 switch malfunctions, BFD can rapidly detect the fault and advertise it to static routing, so as to trigger the system to delete the static route from the RIB, thereby preventing routing errors.

Figure 6-2

Remarks	A and B are routers. Switch is a Layer-2 switch. A and B are connected through the Layer-2 switch.
----------------	--

Deployment

- Configure IP addresses for interconnected interfaces of Router A and Router B.
- Configure static routing on Router A and Router B.
- Set BFD parameters for interconnected interfaces of Router A and Router B.
- Enable BFD support for static routing on Router A and Router B.

6.3 Features

Basic Concepts

Packet Format

Detection packets transmitted by BFD are User Datagram Protocol (UDP) packets, which are classified into control packets and echo packets. Echo packets concern only the local system of a BFD session. Therefore, their formats are not specified. BFD specifies the format of only control packets. Currently, there are two versions (version 0 and version 1) for the format of control packets. Version 1 is adopted by default for establishing a BFD session. If a device receives packets of version 0 from the peer system, the device automatically switches to version 0.

Figure 6-3

Field	Description
Vers	Indicates the BFD protocol version number, which is 1 currently.
Diag	Indicates the cause for the local system's last change in session state, including: 0 -- No Diagnostic. 1 -- Control Detection Time Expired 2 -- Echo Function Failed

Field	Description
	3 -- Neighbor Signaled Session Down 4 -- Forwarding Plane Reset 5 --Path Down 6 -- Concatenated Path Down 7 --Administratively Down
Sta	Indicates the BFD local session state, including: 0 -- AdminDown. 1 -- Down. 2 -- Init. 3 -- Up.
P	Indicates that the transmitter in a BFD session adds this bit in a verification request upon parameter changes, waiting for the peer response.
F	Indicates the bit that must be set in the response packet for responding to the P bit.
C	Indicates the control plane independent. If set, changes of the control plane do not affect BFD detection. For example, if the control plane is OSPF, when OSPF is restarted or experiences graceful restart (GR), BFD can continue to detect the link status.
A	Indicates the authentication present. If set, a session is to be authenticated.
D	Indicates the demand request. If set, the transmitter desires to detect links in Demand mode.
M	Indicates the multipoint bit to be used in point-to-multipoint extensions. It must be set to 0 currently.
Detect Mult	Indicates the detection timeout multiplier. It is used by the detector to calculate the detection timeout time.
Length	Indicates the packet length.
My Discriminator	Indicates the discriminator of the local end connected by a BFD session.
Your Discriminator	Indicates the discriminator of the remote end connected by a BFD session.
Desired Min Tx Interval	Indicates the minimum interval of transmitting BFD packets supported by the local end.
Required Min RX Interval	Indicates the minimum interval of receiving BFD packets supported by the local end.
Required Min Echo RX Interval	Indicates the minimum interval of receiving echo packets supported by the local end. It is set to 0 if the local end does not support the echo function.
Auth Type	(Optional) Indicates the authentication type, including: Simple Password Keyed MD5 Meticulous Keyed MD5 Keyed SHA1 Meticulous Keyed SHA1
Auth Length	Indicates the authentication data length.
Authentication Data	Indicates the authentication data area.

 **Session Status**

A BFD session can be in any of the four basic states: Down, Init, Up, and AdminDown.

1. Down: Indicates that a session is in the Down state or is established just now.
2. Init: Indicates that the local system has communicated with the peer system and desires to bring the session to the Up state.
3. Up: Indicates that a session has been negotiated successfully.
4. AdminDown: Indicates that a session is in the AdminDown state.

BFD migrates the state machine based on the local session state and received BFD packets from the peer end.

A BFD state machine is established and torn down using a three-way handshake mechanism, to ensure that both ends know the status change.

Transmission Interval and Detection Time

Both ends negotiate BFD parameters during the establishment of a BFD session, to determine the transmission interval and detection time.

After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

Overview

Feature	Description
BFD Session Establishment	Establishes a BFD session.
BFD Session Detection	Rapidly detects a bidirectional forwarding path.
BFD Support for Applications	Rapidly advertises the BFD detection result.
BFD Protection	Protects BFD from attacks for stability.
BFD Flapping Dampening	Protects stability of associated applications in the case of line instability.

6.3.1 BFD Session Establishment

BFD detection starts from the establishment of a BFD session.

Working Principle

Session Establishment Process

BFD itself is unable to discover neighbors. It needs an upper-layer protocol to specify a neighbor to establish a session.

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-4

BFD session establishment process:

1. OSPF discovers a neighbor and establishes a connection with the neighbor.
2. OSPF instructs BFD to establish a session with the neighbor.
3. BFD establishes a session with the neighbor.

↘ BFD Session Establishment Mode

The BFD protocol specifies that a BFD session can be established in two modes:

- Active mode

Before the establishment of a session, BFD actively transmits a control packet for establishing a BFD session regardless of whether it receives a control packet for establishing a BFD session from the peer end.

- Passive mode

BFD does not actively transmit a control packet for establishing a BFD session before a session is established but wait till it receives a control packet for establishing a BFD session from the peer end.

i The passive mode is not supported currently.

↘ Negotiation of BFD Session Parameters

Both ends negotiate BFD session parameters during the establishment of a BFD session, to determine the transmission interval and detection time. Pay attention to the following points:

1. BFD session parameters (including **Desired Min Tx Interval**, **Required Min RX Interval**, and **Detect Mult**) must be set for interfaces at both ends. Otherwise, a BFD session cannot be established.
2. Interfaces at both ends negotiate BFD session parameters and detect the session based on the parameters during the establishment of a BFD session.
3. After a BFD session is established, both ends can dynamically negotiate BFD parameters (for example, minimum transmission interval and minimum receiving interval). After protocols at both ends transmit relevant negotiation packets, they adopt the new transmission interval and detection time, without affecting the current state of the session.

6.3.2 BFD Session Detection

Link detection starts after the establishment of a BFD session. BFD periodically transmits BFD control packets. If it fails to receive BFD packets from the peer end within the detection time, it deems that the session is Down and notifies the associated application to accelerate the convergence.

Working Principle

↘ Detection Process

As shown in the following figure, two routers running OSPF and BFD are connected through a Layer-2 switch.

Figure 6-5

Handling procedure after a BFD session is Down:

1. The link between Router A and Switch fails.
2. The BFD session between Router A and Router B is Down.
3. BFD notifies the local OSPF that the forwarding path to the neighbor is faulty.
4. OSPF processes the neighbor Down situation. If a backup forwarding path is available, it starts protocol convergence to enable the alternative forwarding path.

↘ Detection Mode

BFD supports the following detection modes:

- Asynchronous mode

In asynchronous mode, systems transmit BFD control packets periodically to each other. If a system fails to receive BFD control packets from the peer end within the detection time, it advertises that the session is Down.

- Query mode

In query mode, it is assumed that each system has an independent method for confirming its connection with other systems. After a BFD session is established, the system stops transmitting BFD control packets unless it needs to explicitly verify the connectivity. In such a case, the system transmits a shot-sequence BFD control packet. If a system fails to receive a returned packet within the detection time, it advertises that the session is Down. If it receives a response from the peer end, the forwarding path is reachable.

- Echo mode

In echo mode, the local system periodically transmits BFD echo packets and a remote system receives and loops back the packets through the forwarding path. If the local system fails to receive several consecutive echo packets within the detection time, it advertises that the session is Down. The echo function can be used together the preceding two detection modes. The echo packet detection function does not require the involvement of the control plane of the remote system. Packets are returned by the forwarding plane of the remote system, which reduces the delay and ensures faster fault detection in comparison with transmission of control packets. The enabling of the echo function in asynchronous mode can greatly

reduce transmission of control packets because the detection is accomplished by the echo function. The enabling of the echo function in query mode can thoroughly cancel transmission of control packets after a session is established. The echo function must be enabled at both ends of a BFD session. Otherwise, the echo function does not take effect.

-
-  The query mode is not supported and cannot be configured at present.
 -  Only BFD session version 1 supports the BFD echo mode.
 -  The echo mode is not supported for an IPv6 BFD session with the link-local address as the source or destination address.
-

6.3.3 BFD Support for Applications

By BFD support, the associated applications can utilize the fast fault detection of BFD to improve the protocol convergence performance. In general, the fault detection time can be shortened within 1 second.

Working Principle

After BFD support for a certain application is enabled, a BFD session is established based on the BFD configuration. When a link fault occurs, BFD can rapidly identify the fault and notify the associated application to process, thereby improving its convergence. Currently, BFD supports the following applications:

- BFD support for RIP

After BFD support for the Routing Information Protocol (RIP) is enabled, RIP can utilize the BFD fault detection, which is faster than the ND mechanism of RIP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for RIP, see *Configuring RIP*.
-

- BFD support for OSPF

After BFD support for OSPF is enabled, OSPF can utilize the BFD fault detection, which is faster than the ND mechanism of OSPF, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPF, see *Configuring OSPF*.
-

- BFD support for OSPFv3

After BFD support for OSPFv3 is enabled, OSPFv3 can utilize the BFD fault detection, which is faster than the ND mechanism of OSPFv3, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

-
-  For more details about BFD support for OSPFv3, see *Configuring OSPFv3*.
-

- BFD support for BGP

After BFD support for the Border Gateway Protocol (BGP) is enabled, BGP can utilize the BFD fault detection, which is faster than the ND mechanism of BGP, to improve the protocol convergence. In general, the fault detection time can be shortened within 1 second.

 For more details about BFD support for BGP, see *Configuring BGP*.

- BFD support for IS-IS

The Intermediate System to Intermediate System (IS-IS) protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, IS-IS uses BFD to establish a BFD session with a neighbor that is in the Up state and detect the neighbor status. When a BFD neighbor fails, IS-IS immediately performs network convergence. The convergence time can be shortened from 30 seconds (by default, on a point-to-point network, IS-IS hello packets are transmitted at an interval of 10 seconds and the neighbor failure time is triple the interval, that is, 30 seconds) to 1 second.

 For more details about BFD support for IS-IS, see *Configuring IS-IS*.

- BFD support for static routing

After BFD support for static routing is enabled, BFD prevents routers from selecting an unavailable static route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

Different from dynamic routing protocols, static routing does not have the ND mechanism. Therefore, after BFD support for static routing is configured, the next-hop reachability of a static route relies on the BFD session state. If a BFD session detects a fault, the next hop of a static route is unreachable and the static route is not added to the RIB.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the forwarding behavior of static routing is not affected.

 For more details about BFD support for static routing, see *Configuring NSM*.

- BFD support for PBR

After BFD support for PBR is configured, BFD prevents routers from selecting an unavailable policy route as the forwarding path during routing and enables routers to rapidly switch to an available backup forwarding path.

BFD support for PBR is equivalent to that for static routing. BFD tracks and detects the forwarding path to a specified neighbor. When a BFD session fails, BFD notifies the PBR that the next hop is unreachable. Then, the policy route to the next hop does not take effect.

If the remote system deletes a BFD session during the establishment of a BFD session, the BFD session becomes Down. In this case, the system ensures that the PBR forwarding behavior is not affected.

 For more details about BFD support for PBR, see *Configuring PBR*.

- BFD support for VRRP

The BFD support for the Virtual Router Redundancy Protocol (VRRP) can replace the ND mechanism of VRRP to rapidly detect the running status of the active and standby routers. When a fault occurs, it accelerates the active/standby router switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP can also utilize BFD to track a specified neighbor. If the forwarding path to the neighbor fails during a BFD session, it automatically lowers the VRRP priority to a certain extent to trigger active/standby router switching. This configuration takes effect only when the dynamic routing protocol or other applications notify BFD to establish a session with a neighbor.

i For more details about BFD support for VRRP, see *Configuring VRRP*.

- BFD support for VRRP Plus

The BFD support for VRRP Plus can replace the BVF detection conducted by the balancing virtual gateway (BVG) of VRRP Plus to rapidly detect the running status of balancing virtual functions (BVs). When a fault occurs, it accelerates the forwarding entity switching and improves network performance. In general, the fault detection time can be shortened within 1 second.

VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support and only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.

i For more details about BFD support for VRRP Plus, see *Configuring VRRP Plus*.

- BFD support for MPLS

The BFD support for Multiple protocol Label Switching (MPLS) refers that label switched paths (LSPs) use BFD to rapidly detect the neighbor status. The following detection modes are supported:

1. BFD detects static LSPs.
 2. BFD detects LSPs generated by the Label Distribution Protocol (LDP).
 3. BFD can detect reverse links of LSPs by using the IP protocols.
-

i For more details about BFD support for MPLS, see *Configuring MPLS*.

- BFD support for Layer-3 interfaces

BFD supports changing status of Layer-3 interfaces. In interface configuration mode, use the **bfd bind peer-ip** command to detect the direct address of a specified Layer-3 interface. After this CLI command is executed, a BFD session is created and the status of a Layer-3 interface can be changed based on the detection result of the BFD session, for example, BFD Down or BFD Up. This function is often used in various types of fast reroute (FRR), which uses BFD to detect the interface status to implement fast FRR switching.

i Only LDP FRR switching is supported in BFD support for Layer-3 interfaces.

- BFD support for Layer-3 AP member ports

After BFD support for Layer-3 AP member ports is enabled, BFD can rapidly detect a fault occurring on a member port link so that traffic on this link is rapidly distributed to other effective member links. In general, the fault detection time can be shortened within 1 second.

i For more details about BFD support for Layer-3 AP member ports, see *Configuring AP*.

6.3.4 BFD Protection

The BFD protection is used to protect BFD against session flapping caused by attacks (for example, a large number of ping packets attack devices).

Working Principle

The BFD protocol is very sensitive. If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD sessions flap, the BFD protection can be configured to provide protection. If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.

6.3.5 BFD Flapping Dampening

A BFD session may frequently switch over between Down and Up due to link instability. As a result, an associated application (such as static routing) may frequently switch forwarding paths and the running services are affected. The BFD flapping dampening can solve this problem.

Working Principle

A BFD session may frequently switch over between Down and Up. This function allows users to set the delay for status change advertisement. After a BFD session is Up for a certain period of time, BFD notifies an associated application of BFD Up. Otherwise, BFD notifies an associated application of BFD Down.

6.4 Configuration

Configuration	Description and Command				
Configuring BFD Basic Functions	 (Mandatory) It is used to establish a BFD session.				
	<table border="1"> <tr> <td>bfd interval</td> <td>Sets BFD parameters.</td> </tr> <tr> <td>N/A</td> <td> Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides. </td> </tr> </table>	bfd interval	Sets BFD parameters.	N/A	Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides.
	bfd interval	Sets BFD parameters.			
	N/A	Configures the BFD support for applications.  The configuration command varies with the associated applications. For details, see their configuration guides.			
	 (Optional) It is used to configure the BFD detection mode, slow timer, and BDF support for Layer-3 interfaces.				
<table border="1"> <tr> <td>bfd echo</td> <td>Configures the BFD echo mode.</td> </tr> <tr> <td>bfd slow-timer</td> <td>Configures the BFD slow timer.</td> </tr> </table>	bfd echo	Configures the BFD echo mode.	bfd slow-timer	Configures the BFD slow timer.	
bfd echo	Configures the BFD echo mode.				
bfd slow-timer	Configures the BFD slow timer.				
<table border="1"> <tr> <td>bfd bind peer-ip</td> <td>Configures the BFD support for Layer-3 interfaces.</td> </tr> </table>	bfd bind peer-ip	Configures the BFD support for Layer-3 interfaces.			
bfd bind peer-ip	Configures the BFD support for Layer-3 interfaces.				
Configuring BFD Protection	 (Optional) It is used to protect BFD against attacks. 				
	<table border="1"> <tr> <td>bfd cpp</td> <td>Enables BFD protection.</td> </tr> </table>	bfd cpp	Enables BFD protection.		
bfd cpp	Enables BFD protection.				
Configuring BFD Flapping Dampening	 (Optional) It is used to protect associated protocols against BFD flapping.				
	<table border="1"> <tr> <td>bfd up-dampening</td> <td>Configures BFD flapping dampening.</td> </tr> </table>	bfd up-dampening	Configures BFD flapping dampening.		
bfd up-dampening	Configures BFD flapping dampening.				

6.4.1 Configuring BFD Basic Functions

Configuration Effect

- Configure BFD support for applications.
- Establish a BFD session.
- A BFD session detects link faults.

Notes

- Pay attention to the following points when setting BFD session parameters:
 1. It is recommended that parameter settings be consistent at both ends of a BFD session, to ensure that application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding due to different dampening time at both ends.
 2. Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.
- Pay attention to the following points when configuring BFD support for applications:
 1. Ensure that it is enabled on neighbors of a BFD session. Otherwise, a BFD session cannot be established. If a dynamic routing protocol or another application requires BFD to establish a session with a neighbor, the BFD session can also be established.
 2. If the interface specified by a BFD session is different from the actual BFD packet outbound interface because of IP routing, or if the interface specified during BFD session creation is different from the actual BFD packet inbound interface, a BFD session cannot be established.
- Pay attention to the following points when configuring the BFD detection mode:
 1. In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, configure Quality of Service (QoS) policies to ensure that echo packets are processed preferentially or disable the echo function.
 2. The echo detection function of BFD does not support multi-hop detection. Ensure that the echo function is disabled when configuring multi-hops.
 3. The echo mode takes effect only after this mode is enabled at both ends of a BFD session.
 4. Before enabling the echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the **no ip deny land** command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

Configuration Steps

📄 Setting BFD Parameters

- Mandatory.

- BFD parameters need to be set at BFD session egresses of routers at both ends detected by BFD if no special requirements are raised.
- Take into account of transmission bandwidth differences of different interfaces when setting parameters. If the minimum transmission interval and minimum receiving interval are set to very small values, data transmission may be affected due to very large BFD bandwidth occupancy.

Command	bfd interval <i>milliseconds</i> min_rx <i>milliseconds</i> multiplier <i>interval-multiplier</i>
Parameter Description	interval <i>milliseconds</i> : Indicates the minimum TX interval, with the unit of milliseconds. min_rx <i>milliseconds</i> : Indicates the minimum RX interval, with the unit of milliseconds. multiplier <i>interval-multiplier</i> : Indicates the detection timeout multiplier.
Defaults	No BFD session parameter is configured.
Command Mode	Interface configuration mode
Usage Guide	The fast forwarding function must be enabled before the BFD function is enabled on routers.

📌 Enabling the BFD Echo Mode

- (Optional) Ports run in asynchronous mode by default. If a BFD session needs to run in echo mode, the echo mode needs to be configured.
- Complete the configuration on ports of switches or routers.
- A session runs in asynchronous mode as long as either of routers at both ends is configured to run in asynchronous mode. If routers at both ends are configured to run in echo mode by default, a BFD session finally runs in echo mode.

Command	bfd echo
Parameter Description	N/A
Defaults	The BFD echo mode is disabled.
Command Mode	Interface configuration mode
Usage Guide	This command cannot be configured on Layer-3 AP ports. By default, when BFD session parameters are set, the system automatically enables the echo mode. The minimum TX interval and minimum RX interval of echo packets adopt the Interval milliseconds and min_rx milliseconds parameters of a session. Before enabling the echo mode of BFD, run the no ip redirects command on the neighbors of a BFD session to disable the function of ICMP packet redirection, and run the no ip deny land command to disable the Distributed Denial of Service (DDoS) function (prevent the Land-based attack).

📌 Configuring the BFD Slow Timer

- (Optional) The default slow timer is 3,000 milliseconds. The value can be changed as required.
- Configure this function in global configuration mode of switches or routers.

- In BFD echo mode or session building, the slow timer is used to control packets. If the value increases, the required time for negotiating and establishing a BFD session becomes longer, and the time required for transmitting slow BFD packets in echo mode is longer.

Command	bfd slow-timer [<i>milliseconds</i>]
Parameter Description	<i>milliseconds</i> : Indicates the BFD slow timer, with the unit of milliseconds. The value ranges from 1,000 to 30,000 and the default value 3,000 is adopted if it is not set.
Defaults	The transmission interval of slow control packets is 3,000 milliseconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the slow timer in echo mode.

↘ Configuring the BFD Support for Layer-3 Interfaces

- (Optional) Currently, this function is used only when MPLS LDP is used for FRR.
- Configure this function on interfaces of switches or routers.

Command	bfd bind peer-ip <i>src-address</i> [source-ip <i>dst-address</i>] process-pst
Parameter Description	<i>src-address</i> : Indicates the peer IP address of an interface. <i>dst-address</i> : Indicates the local IP address of an interface.
Defaults	BFD support for Layer-3 interfaces is not configured by default.
Command Mode	Interface configuration mode
Usage Guide	This command is used to enable BFD support for Layer-3 interfaces so as to rapidly detect connectivity of Layer-3 interfaces.

↘ Configuring the BFD Support for Applications

- Mandatory.
- This function is disabled by default.
- The configuration command varies with the associated applications. For details, see their configuration guides.
- This function must be configured at both ends so that a BFD session can be established.
- In RIP routing configuration mode, run the **bfd all interfaces** command to enable BFD support for RIP on all interfaces. For details, see *Configuring RIP*.
- In OSPF routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPF on all interfaces. For details, see *Configuring OSPF*.
- In OSPFv3 routing configuration mode, run the **bfd all interfaces** command to enable BFD support for OSPFv3 on all interfaces. For details, see *Configuring OSPFv3*.
- In BGP routing configuration mode, run the **neighbor address fall-over bfd** command to enable BFD support for BGP. For details, see *Configuring BGP*.

- In IS-IS routing configuration mode, run the **bfd all interfaces** command to enable BFD support for IS-IS on all interfaces. For details, see *Configuring IS-IS*.
- In global configuration mode, run the **ip route static bfd [vrf vrf-name] interface-type interface-number gateway [source ip-address]** command to enable BFD support for static routing. For details, see *Configuring NSM*.
- In global configuration mode, run the **ipv6 route static bfd [vrf vrf-name] interface-type interface-number gateway [source ipv6-address]** command to enable BFD support for IPv6 static routing. For details, see *Configuring NSM*.
- Run the **set ip next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for PBR. For details, see *Configuring PBR*.
- Run the **set ipv6 next-hop verify-availability next-hop-address bfd [vrf vrf-name] interface-type interface-number gateway** command to enable BFD support for IPv6 PBR. For details, see *Configuring PBR*.
- Run the **vrrp bfd interface-type interface-number ip-address** command to enable BFD support for VRRP. For details, see *Configuring VRRP*.
- VRRP Plus is based on the VRRP protocol. Therefore, no additional configuration is required for BFD support for VRRP Plus. Only VRRP needs to be enabled on devices at both ends and a BFD session is correctly associated.
- Run the **bfd bind static-lsp peer-ip ip-address source-ip ip-address [local-discriminator discr-value remote-discriminator discr-value] [process-state]** command to enable BFD support for static LSP. For details, see *Configuring MPLS*.
- Run the **bfd bind ldp-lsp peer-ip ip-address nexthop ip-address [interface interface-type interface-number] source-ip ip-address [local-discriminator discr-value remote-discriminator discr-value] [process-state]** command to enable BFD for LDP LSP. For details, see *Configuring MPLS*.
- Run the **bfd bind backward-lsp-with-ip peer-ip ip-address [vrf vrf-name] interface interface-type interface-number [source-ip ip-address] { local-discriminator discr-value remote-discriminator discr-value }** command to enable BFD support for dynamic LSP. For details, see *Configuring MPLS*.

Verification

- The verification command varies with the associated applications. For details, see their configuration guides.

Configuration Example

Configuring BFD support for OSPF

Scenario Figure 6-6	
Configuration Steps	<ul style="list-style-type: none"> ● Configure IP addresses for interconnected interfaces of Router A and Router B. ● Run OSPF on Router A and Router B. ● Set BFD parameters for interconnected interfaces of Router A and Router B.

● Enable BFD support for OSPF on Router A and Router B.

Common Errors

- BFD parameters are not set for device interfaces at one end.
- The BFD support for applications is disabled.
- The BFD support for applications is enabled only at one end.

6.4.2 Configuring BFD Protection

Configuration Effect

- If a BFD-enabled device is attacked (for example, attacked by a large number of ping packets) and BFD session flaps accordingly, the BFD protection can be enabled to provide protection.

Notes

- The BFD basic functions must be configured.
- If both BFD and BFD protection are enabled on a device, the device discards the BFD packet from the previous hop, affecting the establishment of a BFD session between the previous-hop device and other devices.
- This function and limitations are applicable only to switches.

Configuration Steps

▾ Enabling BFD Protection

- Optional.
- Configure this function in global configuration mode on switches or routers.
- The BFD protection function raises the processing priority of BFD packets and ensures normal running of BFD services in a scenario in which devices are attacked.

Description	Command
Displays BFD session information.	show bfd neighbors [<i>vrf vrf-name</i>] [client { ap bgp ospf rip rrp static-route pbr rrp-balance ldp-lsp static-lsp backward-lsp-with-ip pst }] [ipv4 ip-address ipv6 ip-address][details]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs BFD events.	debug bfd event [interface <i>interface-type interface-number</i> ipv4 ip-address ipv6 ipv6-address]
Debugs BFD packets.	debug bfd packet [interface <i>interface-type interface-number</i> ipv4 ip-address ipv6 ipv6-address]

7 Configuring IP Event Dampening

7.1 Overview

When the Layer-3 port on a Layer-3 device frequently goes Up and Down due to manual enabling/disabling or other external causes, the routing table on the device will flap repeatedly. If a routing protocol is configured, the protocol may propagate the flap to the entire network, causing repeated updates and recalculation of neighboring routes, which wastes network bandwidths and destabilizes the network. Repeated route updates and recalculation on devices consume many CPU resources, which affects the normal running of customer networks.

IP Event Dampening detects abnormal Up/Down flapping and automatically suppresses frequent port state changes, which prevents the propagation of single-point link failures by a routing protocol. When the port is restored, it will be automatically unsuppressed, thus reducing network flaps and CPU resource consumption while improving network stability.

Protocols and Standards

- RFC2439: BGP Route Flap Dampening

i At its core, the suppression algorithm used by IP Event Dampening is the same as that used by BGP Route Flap Dampening.

7.2 Applications

Application	Description
Routed Port Flap Dampening	Monitors the state change of the Layer-3 port on a router, and suppresses frequent port flapping.

7.2.1 Routed Port Flap Dampening

Scenario

In a network that runs a routing protocol, when a port on a router connected to another router frequently goes Up and Down, neighboring routes will be repeatedly updated and recalculated. The routing protocol may propagate the flap to the entire network, causing a network flap. IP Event Dampening can be enabled on the connected routers to monitor port state changes and suppress frequent port flapping, thus reducing network flaps and CPU resource consumption while improving network stability.

Figure 7-1

Remarks	A and B are routers.
----------------	----------------------

Deployment

Configure IP Event Dampening on portGE0/1 on Router A and portGE0/1 on Router B respectively.

! The subinterfaces and the virtual templates of interfaces on routers do not support the dampening feature.

7.3 Features

Basic Concepts

Penalty

A port that goes Up or Down gets a penalty for each state change, but the penalty decays exponentially when the port is stable. In this way, port behaviors can be sensed and controlled intelligently.

Suppress Threshold

When the cumulative penalty of a port exceeds a suppress threshold, the port is considered to flap and will be suppressed.

Half-Life Period

The half-life period is the period required for the penalty to decrease to half of the original value when the port is stable. It defines the speed at which the penalty decays exponentially. The shorter the half-life period, the faster the penalty decays, and the faster the port is detected to be stable, but the flap detection sensitivity is reduced.

Reuse Threshold

When the port no longer flaps and its penalty decays to a certain degree (below the suppress threshold), the port is considered to be stable and is unsuppressed.

Maximum Suppress Time

When a port keeps flapping and reaches a very large penalty, the port will not be usable for a long time. To avoid this problem, the maximum suppress time is defined to always maintain the port suppression duration below a certain value no matter how long the port has flapped.

Overview

Feature	Description
Port Flap Suppression	Configure the criteria and parameters of flap suppression on ports to enable switches or routers to identify and suppress frequently flapping ports, which ensures route stability and avoids route flap propagation.

7.3.1 Port Flap Suppression

Working Principle

A port configured with IP Event Dampening is assigned a penalty. The port gets a penalty of 1,000 each time when it goes Down, but the penalty decreases with time. If the port goes Down again, the penalty increases accordingly. When the cumulative penalty exceeds the suppress threshold, the port will be suppressed. For the affected upper-layer protocol, the suppressed port is always Down no matter what the actual port state is. When the penalty decreases to the reuse threshold, the port will be unsuppressed, and the upper-layer protocol can sense the actual port state.

If a Layer-3 port is not configured with IP Event Dampening, or is not suppressed by it, the routing protocol or other protocol concerned about the port status still work normally. When the port is suppressed, the upper-layer protocol considers the port to be Down. Any state change of the port before the port is unsuppressed does not affect the routing table and the route calculation and advertisement performed by the upper-layer routing protocol.

Related Configuration

Configuring IP Event Dampening

- By default, IP Event Dampening is disabled on Layer-3 ports.
- Run the **dampening** [*half-life-period* [*reuse-threshold* *suppress-threshold* *max-suppress* [**restart** [*restart-penalty*]]]] command to enable or disable IP Event Dampening on Layer-3 ports.

7.4 Configuration

Configuration	Description and Command
Enabling IP Event Dampening	 (Mandatory) It is used to suppress Layer-3 port flapping.
	dampening Configures IP Event Dampening.

7.4.1 Enabling IP Event Dampening

Configuration Effect

When a port configured with IP Event Dampening keeps flapping until the predefined threshold is exceeded, the port is set to Down.

Notes

- When a Layer-3 port on a switch is converted to a Layer-2 port (for example, from a routed port to a switch port), the IP Event Dampening configuration on the port will be deleted.
- Only the main interface on a router can be configured with IP Event Dampening. The configuration takes effect for all subinterfaces of the main interface, but you cannot run the **dampening** command directly on subinterfaces and virtual templates.

Configuration Steps

▾ Configuring IP Event Dampening

- Mandatory.
- Perform the configuration in Layer-3 interface configuration mode.
- You can specify the half-life period, reuse threshold, suppress threshold, maximum suppress time, and initial penalty. If you do not set these parameters, their default values will be used.

Verification

Use any one of the following commands to check whether the configuration takes effect:

- **show running-config**
- **show interfaces [interface-id] dampening**, which is used to check the IP Event Dampening configuration on a specified port

Related Commands

▾ Enabling IP Event Dampening on a Port

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Enables debugging of IP Event Dampening.	debug dampening interface

8 Configuring VSU

8.1 Overview

In order to improve the reliability of networks, the two devices at core layer and convergence layer of traditional networks are configured with two cores to provide redundancy. Access and convergence devices are respectively connected to the cores through two links. The following figure shows a typical traditional network architecture. Redundant network architecture increases the complexity of network design and operation. At the same time, a large number of redundant links reduce the utilization of network resources and return on investment.

Figure 8-1 Traditional Network Architecture

Virtual Switching Unit (VSU) is a kind of network system virtualization technology that supports combining multiple devices into a single virtualized device. As shown in Figure 8-2, access, convergence and core layer devices can respectively form VSUs, and then these VSUs connect to one another to form an end-to-end VSU network. Compared with traditional network, this networking can:

- Simplify the network topology.
- Reduce the costs of network management and maintenance.
- Shorten application recovery time and service interruption time.
- Enhance the utilization of network resources.

Figure 8-2 End-to-End VSU Networking

8.2 Applications

Application	Description
Managing Multiple Devices in a Unified Manner	Uses multiple physical devices as a logical device for unified management.
Simplifying Networking Topology	Uses a VSU as a logical device to simplify the networking topology.

8.2.1 Managing Multiple Devices in a Unified Manner

Scenario

When multiple physical devices form a VSU system, the physical devices can be viewed as a logical device. All configurations are managed on the global master device.

As shown in Figure 8-3, four devices (numbered as 1, 2, 3, and 4 from left to right) form a VSU system. Device 1 is the global master device, device 2 is the global slave device, and devices 3 and 4 are the global candidate devices.

- All devices are configured simply on the global master device.

Figure 8-3

Remarks	The devices from left to right in Figure 8-3 are Device 1, Device 2, Device 3 and Device 4. For details on VSL, see the description in section 1.3.1.
----------------	---

	Device 1 is the global master device. Device 2 is the global slave device. Devices 3 and 4 are the global candidate devices.
--	--

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.
- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when faulty.
- The global candidate devices are involved in data forwarding and do not run control-plane protocols. When the global slave device is faulty, a global candidate device can take over the work of the global slave device. In this case, when the global master and slave devices are faulty, the VSU system will restart.

8.2.2 Simplifying Networking Topology

Scenario

In traditional networks as shown in Figure 8-4, redundant devices and lines need to be added to increase the networking reliability; however, many algorithms also need to be introduced to prevent loops, which make the networking more complex. In the VSU system, all devices are viewed as a logical device. Different devices back up each other, and no loop prevention algorithm needs to be introduced, which can simplify the network.

- Two aggregate switches form a VSU system. It is unnecessary to configure a loop prevention algorithm. The two switches are redundant mutually.
- The access switch is connected to the aggregate switches through the uplink AP.
- When a switch in the VSU system is faulty, the other link still works.

Figure 8-4

Deployment

- The global master device controls the entire VSU system, runs control-plane protocols and is involved in data forwarding.

- The global slave device is involved in data forwarding, does not run control-plane protocols, and works as the backup and takes over the work of the global master device when the global master device is faulty.
- The access switch is oriented to users and allows access by users' devices.

8.3 Features

Basic Concepts

VSU System

VSU system is a single logical entity consisting of two or multiple devices in traditional network architecture. For example, the convergence layer VSU system as shown in the following figure can be seen as a single device that interacts with the core layer and access layer.

Figure 8-5 Convergence layer VSU

In the above VSU network structure, the member devices form a logical entity through internal links and the access layer devices are connected to the VSU through aggregated links. In this way, there is no layer 2 loop between the access and convergence layers.

Figure 8-6 Access layer VSU

Except the core and convergence layer devices, the access layer devices can also form a VSU system. A server that requires high availability can adopt multiple network cards to form an Aggregate Port (AP) to connect access layer devices. Since AP can only connect to the same access device, the risk of single device fault increases. In this case, VSU can be used to solve the problem. In the VSU mode, a server adopts multiple network cards and binds them into an AP to connect different member devices in the same VSU group. This way can prevent single point failure and network interruption caused by single link failure.

↘ VSU Domain ID

A VSU domain has only one ID. Only the devices with the same domain IDs can form a VSU system.

↘ Member Device ID

Every member device in a VSU system has a unique ID, namely, Switch ID. Switch IDs can be used in device management or configuring interfaces on member devices. You need to configure an ID for a device when adding the device to a VSU system and ensure that the ID is unique in the same VSU system. If an ID conflict occurs, the VSU system will reserve one device according to priority.

↘ Member Device Role

A VSU system consists of several devices. When establishing a VSU system, you need to select a global master device and a global slave device. All other devices are global candidate devices. A global master device is elected from multiple devices based on an election protocol. All other devices are global slave devices in the 1: N hot standby mode. When the 1:1 hot standby mode is supported, one device is the global master device, one device is the global slave device, and all other devices are global candidate devices.

The global master device is responsible for controlling the entire VSU system, running control plane protocols and participating in data forwarding. Other devices, including the global slave devices and candidate devices, participate in data forwarding but do not run control plane protocols. All received control plane data flows are forwarded to the global master device for processing.

The global slave device also receives the statuses of the global master device in real-time and provides 1:1 or 1:N redundancy with the global master device. If the global master device becomes faulty, the global slave device will take over services from the master device and manage the entire VSU system.

 The following is the method for selecting the master device of a VSU system:

1. Rules for selecting the master device of a VSU system include (Continue with the next rule if the previous rule does not help in selecting the master device): a) Select the currently running host as the master device with the highest priority (All devices are not master devices during startup). b) Select the device with the highest priority as the master device. c) Select the device with the lowest device No. as the host. d) Select the device with the smallest MAC address as the master device.
2. In the 1:N hot standby mode, select the device that has the most familiar configurations with the master device as the slave device to prevent dual active devices. The selection order is: the nearest/the highest priority/the smallest MAC address.
3. VSU system supports hot adding a support device. Even the hot added device has a higher priority than the master device has, the VSU system does not perform active/standby switch.
4. The startup order of member device may affect the election of master device. A member device may not join in the VSU system because it starts up too slowly. In this case, the device will be hot added to the VSU system. Even the device has a higher priority than the master device, the VSU system does not perform active/standby switchover.

Overview

Feature	Description
---------	-------------

Virtual Switching Link (VSL)	In a VSU system, a virtual link is used to connect all devices.
Topology	Describes the internal topology of a VSU system.
Dual-Active Detection (DAD)	Avoids that dual master switches coexist in a VSU domain.
System Management	Describes possible connections between external devices and VSU devices.
Quick Blinking Location	Manages devices in the VSU system.

8.3.1 Virtual Switching Link (VSL)

Working Principle

➤ VSL

The VSU system is a network entity that consists of multiple devices. These devices need to share control information and part of data streams. The VSL is a special link used for transmission of control information and data streams among devices of the VSU system. For example, the VSL can be established between two devices through 10 Gigabit Ethernet interfaces. Figure 8-7 shows the position of the VSL in the VSU system.

Figure 8-7 VSL

The VSL exists in the form of AP groups. The data streams transmitted through the VSL balance load among the aggregation port members according to the traffic balancing algorithm.

➤ VSL Traffic

The control streams transmitted through the VSL between devices include:

1. The protocol packets received by the member devices: These protocol packets need to be forwarded through the VSL to the global master device for processing.
2. The protocol packets processed by the global master device: These protocol packets need to be forwarded through the VSL to the interfaces of other member devices and then sent to the peer devices by these interfaces.

The data streams transmitted through the VSL between devices include:

1. The data stream flooded on the VLAN
2. The data streams that need to be forwarded across devices and transmitted through the VSL

Furthermore, the internal management packets of the VSU system are also transmitted through the VSL. The management packets include the protocol information switched by the hot backup and configuration information delivered by the host to other member devices.

i In terms of the switched port analyzer (SPAN) function, the interface associated with the VSL cannot be regarded as the source port or destination port of the SPAN.

↘ VSL Failure

If a certain member link connected to the VSL AP group fails to work, the VSU will adjust the configurations of the VSL aggregation port automatically to prevent the traffic from being transmitted through the faulty member link.

If all member links are disconnected to the VSL AP group, the VSU topology will change. If the original VSU topology is a ring topology, the ring will convert into a line. For details, see topology ring and line conversion in the section of *Topology Changes*.

↘ Detecting Error Frames on a VSL Interface

When a large number of consecutive error frames are detected on a VSL interface, the interface must be disabled and switched to another VSL interface. The detection method is as follows:

If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interface every 5 seconds by default. If the number of error frames is greater than the value of *num* as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for the value of *times*, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Different user scenarios have different requirements for *num* and *times*. The default value of *num* is 3 and that of *times* is 10. If users have strict requirements on the scenarios, select smaller values for *num* and *times*; if reverse, select greater values.

8.3.2 Topology

The VSU system supports line topology and ring topology. Devices are connected through a VSL to form a line that is called the line topology.

Working Principle

↘ Topology

The line topology is simple. It uses a very few ports and cables. Two devices are connected with a communication link only. Therefore, the VSL has low reliability.

Figure 8-8 Line topology

Except for the line topology, devices can also form a ring topology, as shown in Figure 8-9. In the ring topology, the two communication links between devices can back up for each other and perform link redundancy to improve the reliability of the VSU system.

Figure 8-9 Ring Topology

- i You are advised to select the ring topology for the VSU system, thus the normal operation of the whole VSU system will not be affected by any single faulty device or VSL.
- i Besides selecting the ring topology networking, you are advised to configure multiple VSLs for every VSL member to improve the reliability of a single VSL. At least two links are recommended and a maximum of four links can be configured. A reasonable configuration comprises more than two VSLs crossing different cards.

↘ **Topology Convergence**

Before the establishment of the VSU, the member devices need to discover neighbors through topology discovery protocols and check devices in the VSU system to confirm the range of the management domain. Then a global master device is selected to manage the whole VSU system and a global slave device is selected for backup of the master device. Then the whole VSU topology is converged. As the start up time differs for different devices, the first convergence time of the topology is also different.

↘ **Topology ring and Line Conversion**

In a ring topology, if a VSL link is disconnected, the ring topology will convert into a line topology. The whole VSU system will still run normally without network disconnection. To prevent other VSL links and nodes from being faulty, you are advised to locate the VSL failures and recover the availability of the VSL. After the VSL link is recovered, the line topology will convert into the ring topology.

Figure 8-10 Ring-to-line and line-to-ring

↘ **Topology Splitting**

In the line topology, if the VSL link is disconnected, the line topology will be split, as shown in Figure 8-11. A VSU group is split into two groups. In this condition, two devices with the absolutely same configurations may exist on the network, which will cause abnormal operation of the network. Therefore, the multi-active detection (MAD) function (for details, see 1.1.4.6 Multi-Active Detection) needs to be deployed to solve the problem of topology splitting.

Figure 8-11 Topology splitting

↳ **Topology Combining**

If the two VSU groups are connected through the VSL link, the line topology will be combined. During the topology combining, restart one VSU group and then hot add the other VSU group.

The principle of topology combining: Minimizing influences on the services during topology combining. The rules are as follows (Judge from the first item. If you cannot select the optimal topology, continue to judge the next item):

- Use the device priority as the first criteria for judging topology combining. Reserve the VSU group containing a device with the highest priority.
- If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
- If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the global master switches).

Figure 8-12 Topology combining

 During topology combining of two VSU groups, the two VSU groups need to be elected. The VSU group that fails the election will restart automatically and hot add to the other VSU group.

8.3.3 Dual-Active Detection (DAD)

Working Principle

When the VSL is disconnected, the slave device switches to the master device. If the original master device is still running, a series of problems including IP address conflict on the LAN will be caused due to there are two master devices and their configurations are the same completely. In this condition, the VSU system must detect the two devices and take recovery measures. The VSU system provides two methods to perform MAD as follows:

- Bidirectional forwarding detection (BFD)
- AP-based detection

↳ MAD Rules

1. Select the VSU group with the highest priority.
2. If the previous item cannot help make a judgment, select the VSU group with more physical devices.
3. If the previous item cannot help make a judgment, select the VSU group with a higher health. (Health: total bandwidth of all physical interfaces (except for management and VSL interfaces) in the UP state in the topology.)
4. If the previous item cannot help make a judgment, select the VSU group with a smaller switch ID (that of the two global master switches).
5. If the previous item cannot help make a judgment, reserve the VSU group with a smaller MAC address (that of the two global master switches).
6. If the previous item cannot help make a judgment, reserve the VSU group with a greater startup time (that of the global master switches).

 If DAD is not configured, network interruption may be caused after topology splitting.

↳ BFD

The VSU system supports the BFD to detect multiple master devices. Figure 8-13 shows the topology. A link is added for the two devices on the edges for MAD specially. When the VSL link is disconnected between the global master and slave devices, two master devices exist concurrently. If the BFD function is set, the two master devices will send the BFD packets to each other through the BFD link. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules (for details, see the topology combining rules in the section 1.1.4.4 *Topology Changes*) and enter the recovery state to avoid network abnormality.

Figure 8-13 BFD

- ⚠ When there is a pair of BFD links, you are advised to deploy the detection links at the two ends of the topology.
- ⚠ You need to adopt the extension BFD and you cannot configure the dual-active detection port by using the existing BFD configurations and commands.

➤ **MAD**

The VSU system also supports the MAD dual-active detection mechanism. Figure 8-14 shows the topology. The VSU system and the upstream device both need to support the MAD function. When the VSL link is disconnected, two master devices exist concurrently. The two master devices respectively send the MAD packets to the member ports of the MAD-APs and then the MAD packets are forwarded to each other through the upstream device. As shown in Figure 8-14, the MAD-AP has four member ports. Each member port is connected to a different device of the VSU system. When the topology splitting occurs, the four member ports all send and receive the MAD packets. Thereby the same devices are detected on the current system. Finally shut down the VSU system of a master device according to some rules (for details, see the topology combining rules in the section 1.1.4.4 *Topology Changes*) and enter the recovery state to avoid network abnormality.

Figure 8-14 MAD based on upstream and downstream devices

- ✔ In the topology above, the upstream device must be Nodexon device and support the MAD packet forwarding function.

8.3.4 VSU Traffic Forwarding

Working Principle

➤ **Cross-device AP Group**

An AP binds multiple physical links together to form a logical link. The VSU system supports the AP across the member devices.

As shown in Figure 8-15, two devices form a VSU group. The external access device Switch A is connected to the VSU in the form of the AP. In terms of Switch A, there is no difference between the AP in Figure 8-15 and the common AP group.

Figure 8-15 Cross-device aggregation port

📌 Troubleshooting

You are advised to configure the cross-device AP with the physical link between the peripheral device and each VSU device. On the one hand, the VSL bandwidth can be reserved (prioritize the AP member of the same device as the egress to transmitted the cross-device AP traffic and prevent unnecessary traffic from being transmitted through the VSL link). On the other hand, the network reliability can be improved (if a certain device is faulty, the member ports of normal devices can work normally).

The follows sections describe the possible faults of the cross-device AP and the consequences.

- Single link failure

If a single link of the cross-device AP is faulty but other links still work normally, the cross-device AP will reallocate the traffic for the remaining normal links.

- Link failure of all cross-device AP member ports on the global master device

If the links of all cross-device AP member ports on the global master device fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the global master device, the system will forward the data stream to the corresponding egress on the global master device through the VSL link.

The control plane protocols are still running on the global master device. Therefore, the protocol packets that enter the VSU system need to be forwarded to the global master device through the VSL link for protocol computing.

- Failure of all links of other member devices

If all links of the cross-device AP and a single device A fail to work, only the member ports of other member devices continue working normally. In terms of the data stream transmitted through the AP to the VSU system, if the data stream forwarding egress is on the member device A, the system will forward the data stream to the corresponding egress on the member device A through the VSL.

- Failure of all links

If all links of the cross-device AP fail to work, the interface status will be Link-Down.

- Global master device fault

If the global master device is faulty, the hot backup switching is performed to switch the original slave device to the master device. Meanwhile, the member ports on other member devices continue working. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream to normal links.

- Member device fault

If a member device is faulty, the AP member link connected to this member device is disconnected. However, other member links still work normally. The link failure is detected on the peer device connected to the VSU through this AP. Therefore, the traffic balancing algorithm needs to be adjusted to allocate the data stream forwarding paths to normal links.

↘ Traffic Balancing

In a VSU system, traffic may have multiple egresses. The AP and ECMP have their own traffic balancing algorithms, for example, using destination or source MAC addresses. For details, see the *Configuring Aggregate Port*. The local forwarding first (LFF) can be configured detailed in this configuration manual. Packets received by a device are forwarded on this device first. In this way, packets can be forwarded to other devices without using a VSL.

8.3.5 System Management

Working Principle

↘ Access to the Console

The master device console of VSU system manages multiple devices on the system simultaneously. The consoles of the slave and candidate devices do not support command line input. However, you can configure the VSU system on the master device for a specified member device and log in to the master device console through the serial port of the slave device. A session can be used to redirect to the master console of a device.

↘ Slot Naming

In terms of the device, in the VSU mode, the slot is named with the device number (Switch ID). Therefore, the slot number turns from one-dimensional into two-dimensional. For example, cable clip 1/1 indicates the slot numbered 1 of the slot 1 on a member device.

↘ Interface Naming

In the VSU working mode, a slot number may occur in multiple devices. Therefore, the interface is named with the device number (Switch ID).

For example, interface gigabitEthernet 1/0/1 indicates the Gigabit port 1 on the slot 0 of the device whose ID is 1; interface gigabitEthernet 2/0/2 indicates the Gigabit port 2 on the slot 0 of the device whose ID is 2.

↘ Access to the File System

In the VSU working mode, you can access to the file system on other member devices from the master device. The detailed access method is the same to that of the local file system. The unique difference is that different URL prefixes are used.

↘ System Upgrade

Generally the VSU system requires version consistency of the main program version numbers of the member devices. However, there are so many member devices that it takes too much time and energy to perform upgrade one by one in the standalone mode and it is also easy to make mistakes. Nodexon switches provide consummate system upgrade solution to help you with system upgrade by adopting the two methods as follows:

- When the VSU system is being established: the system will automatically align the main program version numbers of all member devices. Once the main program versions are discovered inconsistency, the main program of the master device will be selected to be synchronized to all member devices.
- After the VSU system is established: the main program version will be synchronized to all member devices automatically by using the file that is downloaded by the TFTP.

● **SYSLOG**

All member devices of the VSU system can display the SYSLOG. The SYSLOG generated by the master device is displayed on the master device console with the same format to that in the standalone mode. The SYSLOG generated by other member devices is also displayed on the master device console, but the message format is different from that in the standalone mode because the device number information is added.

For example, the SYSLOG information generated in the standalone state is "%VSU-5-DTM_TOPO_CVG:Node discovery done. Topology converged." The SYSLOG information generated by the member device numbered 3 is "%VSU-5-DTM_TOPO_CVG:(3) Node discovery done. Topology converged."

8.3.6 Quick Blinking Location

In a network cabling environment, the equipment room where switches are located and the operation console are often at different places. If there are many devices in the environment, network administrators cannot easily locate the locations of specific devices.

Quick blinking location provides network administrators with a method for locating devices by means of quick blinking. By enable this function for a device on the console, you can easily find the corresponding device in the equipment room.

-  When quick blinking location is enabled, the status LED cannot show original status until the quick blinking location is disabled.

8.4 Configuration

Configuration	Configuration and Command	
Configuring VSU in the Standalone Mode	 (Mandatory) It is used to configure VSU in the standalone mode.	
	switch virtual domain	Configures the domain ID.
	switch	Configures the switch ID.
	switch priority	Configures the switch priority.
	vsl-port	Enters the VSL interface configuration mode.

Configuration		Configuration and Command	
		port-member interface	Configures the VSL member interface.
		switch convert mode virtual	Changes the standalone mode to the VSU mode.
		 (Optional) It is used to configure the device attributes in the VSU mode.	
		switch description	Configures the device description.
		switch crc	Configures error frame check.
		 (Optional) It is used to configure the device attributes in the VSU mode.	
Configuring VSU in the VSU Mode	Configuring VSU Attributes	switch domain	Changes the domain ID.
		switch renumber	Changes the switch ID.
		switch description	Configures the device description.
		switch crc	Configures error frame check.
	Configuring the VSL	 (Optional) It is used to configure a VSL.	
		vsl-port	Enters the VSL interface configuration mode.
		port-member interface	Configures a VSL member interface.
	Configuring Dual-Active Detection	 (Mandatory) It is used to configure DAD.	
		dual-active detection	Configures DAD.
		dual-active bfd interface	Configures the BFD DAD interface.
		dual-active interface	Configures an AP as a DAD interface.
		dual-active exclude interface	Configures an excluded interface.
Configuring Traffic Balancing	 (Optional) It is used to configure traffic balancing in the VSU mode.		
	switch virtual aggregateport-lff enable	Configures the AP LFF mode.	
	switch virtual ecmp-lff enable	Configures the ECMP LFF mode.	
Changing the VSU Mode to the Standalone Mode	 (Optional) It is used to change the VSU mode to the standalone mode.		
	switch convert mode standalone	Changes the VSU mode to the standalone mode.	
		 (Optional) It is used to quickly locate a device.	
		led-blink	Enables quick blinking location.

8.4.1 Configuring VSU in the Standalone Mode

Configuration Effect

Start up the switch in the standalone mode to set relevant VSU parameters to establish the VSU system.

Configuration Steps

Configuring VSU Attributes

- A switch starts in the standalone mode by default. You need to set the same domain ID on the two device of the established VSU system. The domain ID must be unique within the local area network (LAN). Furthermore, you need to set the ID of each device in the VSU.
- Run the **switch virtual domain** *domain_id* command to configure the domain ID. This command is mandatory.
- Run the **switch** *switch_id* command to configure the device ID in the VSU. This command is mandatory. For devices with the same priorities in the VSU system, a device with the smallest device ID is selected as the global master device.
- Run the **switch** *switch_id* **priority** *priority_num* command to configure the device priority. This command is mandatory.
- The value ranges from 1 to 255. A larger value means a higher priority.
- Run the **switch** *switch_id* **description** *switch1* command to configure the device alias. This command is optional. The default name is Nodexon. For easy identification of devices in the network environment, this item can be selected to set the device alias.

Command	switch virtual domain <i>number</i> <small>A maximum of 32 characters are allowed</small>
Parameter	<i>number</i> : Indicates domain ID of the VSU
Description	
Defaults	The default domain ID is 100.
Command Mode	Global configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU. The domain ID must be unique within the LAN.

Command	switch <i>switch_id</i>
Parameter	<i>switch_id</i> : indicates the switch ID in the VSU system. The value varies with products.
Description	
Defaults	The default device ID is 1.
Command Mode	Domain configuration mode
Usage Guide	<p>The device ID identifies each virtual device member. In VSU mode, the interface name format changes to "switch/slot/port" from "slot/port", in which "switch" is the device ID.</p> <p>If either device are active or if the role of the just started device is uncertain and both have the same priority, the device with a smaller ID is elected as the active one.</p> <p>This command can be only used to modify the device ID in standalone mode. In VSU mode, run the switch renumber command to modify the device ID. The modified device ID takes effect only after you restart the device, regardless of in standalone mode or in VSU mode.</p>

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>priority_num</i> : Indicates the switch priority, ranging from 1 to 255.
Defaults	The default device priority is 100.
Command Mode	Domain configuration mode
Usage Guide	<p>A larger value means a higher priority. A device with the highest priority is chosen as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of <i>switch_id</i>. In the standalone mode, if <i>switch_id</i> is set to 1, running the switch 2 priority 200 command does not work. You can first set <i>switch_id</i> to 2 and then run the switch 2 priority 200 command. In the VSU mode, <i>switch_id</i> indicates the ID of the currently running switch. If the ID does not exist, the configuration does not take effect.</p>

Command	switch <i>switch_id</i> description <i>dev-name</i>
Parameter	<i>switch_id</i> : Indicates the device ID.
Description	<i>dev-name</i> : Indicates the device description, no greater than 32 characters.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	This command is configured on a device in whether standalone or VSU mode and takes effect immediately after configuration.

 The command used for configuring a priority can modify the priority only rather than modify a switch ID. Therefore, you must enter the current switch ID correctly for the configuration. For example, you have set the switch ID to 1. If you enter **switch 2 priority 100**, the priority configuration cannot take effect.

Configuring the VSL

- To establish the VSU system, you need to decide which ports are configured as the VSL member ports.
- Run the **vsl-port** command to enter the VSL interface configuration mode. This command is mandatory.
- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is mandatory.
- When the device enters the VSL interface configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter	N/A
Description	
Defaults	N/A

Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter Description	<i>interface-name</i> : Indicates a two-dimensional interface name, such as Tengigabitethernet 1/1 and Tengigabitethernet 1/3. copper : Indicates the copper interface attribute. fiber : Indicates the optical interface attribute.
Defaults	N/A
Command Mode	VSL interface configuration mode
Usage Guide	Add a member interface of the VSL link. <i>interface-name</i> indicates the two-dimensional interface name in the standalone mode. The two-dimensional interface can be the 10 Gigabit interface or Gigabit interface. (The Gigabit interface can be an opto-copper interface. If the media type is not specified, the Gigabit copper interface is adopted by default.) For an opto-copper interface, you must specify its optical or copper interface attribute. A VSL interface for a device must be a 10 Gigabit interface. You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

 In the standalone mode, the VSL configurations cannot take effect immediately unless the device shifts into the VSU mode and restart.

 **Configuring Error Frame Check**

- Run the **switch crc** command to configure error frame check. This command is optional. Run this command to modify the default method for checking error frames.
- If error frames are found on a VSL interface, perform error frame correction. The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. If multiple VSL links are available when error frames are detected, the VSL will be switched. The last VSL will not be switched in order to prevent topology splitting.

Command	switch crc errors <i>error_num</i> times <i>time_num</i>
Parameter Description	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once. <i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
Defaults	The default value of errors is 3; the default value of times is 10.
Command Mode	Domain configuration mode

Usage Guide	The system detects the VSL interfaces every 5 seconds by default. If the number of error frames is greater than 3 as compared with that detected last time, it is assumed that error frames are detected once. If error frames are detected consecutively for 10 times, it is assumed that the interface is abnormal. The default action for an abnormal interface is displaying a log prompt. You can set the action to disabling the interface. If the interface is disabled, you must recover it by unplugging and plugging it.
--------------------	--

- ✔ Different products have different requirements for error frame check and different processing for VSL interfaces. In version 11.0, error frame check is configurable.

↘ Changing the Standalone Mode to the VSU Mode

- Use the **switch convert mode virtual** command to change the standalone mode to the VSU Mode.
- In the standalone mode, the software will take the following actions after you run the **switch convert mode virtual** command.

Back up the global configuration file *config.text* in the standalone mode as *standalone.text* for subsequent use.

Clear the contents of the configuration file *config.text*.

Write the relevant VSU configurations to the special configuration file *config_vsu.dat*.

- If there is a *virtual_switch.text* file on the switch, the system will prompt you whether to overwrite the contents of the file *virtual_switch.text* to the file *config.text* (the file *virtual_switch.text* is a backup file for the file *config.text* when the switch shifts from the VSU mode to the standalone mode). Then you can click **Yes** or **No**. Finally the switch restarts in the VSU mode and reads VSU parameters in the file *config_vsu.dat*.

Command	switch convert mode virtual
Parameter	N/A
Description	
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	Change the standalone mode to the VSU mode.

Verification

Run the **show switch virtual config [switch_id]** command to check the VSU configuration of the current switch in the standalone mode.

Command	show switch virtual config [switch_id]
Parameter Description	<i>switch_id</i> : Indicates the switch ID. After this parameter is specified, only the VSU configuration of the specified device is displayed.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the VSU configuration in the standalone or VSU mode.

Switch-2

```
Nodexon#show switch virtual config
switch_id: 2 (mac: 0x1201aeda0E)
!
switch virtual domain 100
!
switch 2
switch 2 priority 100
!
switch convert mode virtual
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch crc errors 10 times 20
!
```

Common Errors

- ✔ A VSL interface of a device must be 10 Gigabit or higher.

8.4.2 Configuring VSU in the VSU Mode

8.4.2.1 Configuring VSU Attributes

Configuration Effect

During the VSU system running, you can modify the parameters, such as domain ID, switch ID, and priority of the master device or the slave device. However, you can only log in to the VSU master device console to modify these parameters, but cannot enter the global configuration mode from the slave device console.

Notes

- Among the commands above, the all configuration commands take effect only after the switch restarts except the **switch sw_id description switch1** command that can take effect immediately.

Configuration Steps

↘ Entering the Domain Configuration Mode

- Optional.
- Run this command in the VSU mode to enter the domain configuration mode. Switches with the same domain ID form a VSU system. You can modify or configure the domain ID, switch priority, and switch ID only after entering the domain configuration mode in the VSU mode.

Command	switch virtual domain <i>domain_id</i>
Parameter Description	<i>domain_id</i> : Indicates the virtual domain ID of the VSU system.
Defaults	The default domain ID is 100.
Command Mode	Global configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

↘ Changing the Domain ID

- Optional.
- To modify the value of *domain_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> domain <i>new_domain_id</i>
Parameter Description	<i>switch_id</i> : Indicates the ID of the currently running switch in the VSU mode, ranging from 1 to 8. <i>new_domain_id</i> : Indicates the modified domain ID, ranging from 1 to 255.
Defaults	The default domain ID is 100.
Command Mode	Domain configuration mode
Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.

↘ Changing the Switch ID

- Optional.
- To modify the value of *switch_id* for a device, you can configure this item on the master device console of the VSU system.

Command	switch <i>switch_id</i> renumber <i>new_switch_id</i>
Parameter Description	<i>switch_id</i> : Indicates the ID of a switch. In a VSU system, the switch ID ranges from 1 to 16 for cassette switches, and from 1 to 4 for device switches. <i>new_switch_id</i> : Indicates the modified switch ID.
Defaults	N/A
Command Mode	Domain configuration mode

Usage Guide	Run this command only in the VSU mode. In addition, the setting can take effect only after the device is restarted.
--------------------	---

↘ Changing the Switch Priority

- Optional.
- To modify the priority of a device, you can configure this item on the master device console of the VSU system.
- A larger value means a higher priority. Select the device with the highest priority as the master device.

Command	switch <i>switch_id</i> priority <i>priority_num</i>
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>priority_num</i> : Indicates the switch priority, ranging from 1 to -255 for cassette switches.
Defaults	The default priority is 100.
Command Mode	Domain configuration mode
Usage Guide	<p>A larger value means a higher priority. Select the device with the highest priority as the master device. You can run this command in the standalone or VSU mode. The modified priority takes effect only after you restart the device.</p> <p>This command is not used to modify the value of switch_id. In the standalone mode, if switch_id is set to 1, running the switch 2 priority 200 command does not work. You can first set switch_id to 2 and then run the switch 2 priority 200 command. In the VSU mode, switch_id indicates the ID of the currently running switch. If the ID does not exist, the configuration does not take effect.</p>

↘ Configuring the Device Description

- Optional.
- To configure the description for a device, you can configure this item on the master device console of the VSU system.
- Run the **switch** *switch_id* **description** *switch1* command to configure the device description. A maximum of 32 characters are allowed.

Command	switch <i>switch_id</i> description <i>dev-name</i>
Parameter	<i>switch_id</i> : Indicates a switch ID for which a priority needs to be configured.
Description	<i>dev_name</i> : Indicates the device name.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	You can run this command in the standalone or VSU mode. The configuration takes effect immediately in the VSU mode.

↘ Configuring Error Frame Check

- Optional.
- Run the **switch** **crc errors** *error_num* **times** *time_num* command to configure the conditions for triggering error frame check.

Command	switch crc errors <i>error_num</i> times <i>time_num</i>
Parameter Description	<i>error_num</i> : Configures the increase of error frames between two detections. When the number of error frames is greater than the increase, it is assumed that error frames are detected once. <i>time_num</i> : Configures the number of times after which an action needs to be taken (the action can be displaying a prompt or disabling the interface).
Defaults	The default value of errors is 3 ; the default value of times is 10 .
Command Mode	Domain configuration mode
Default Level	14
Usage Guide	N/A

📄 **Saving the Configuration File**

Run the **exit** command to exit from the virtual device configuration mode and run the **write** command to save the configurations to the *config_vsu.dat* file.

Verification

Use the **show switch virtual [topology | config]** command to display the current VSU running information, topology or configuration parameters.

Command	show switch virtual [topology config]
Parameter Description	Topology : Indicates topology information. Config : Indicates the VSU configurations.
Command Mode	Privileged EXEC mode
Usage Guide	View the domain ID, and the device ID, status and role of each device.

Configuration Example

📄 **Configuring VSU Attributes**

Scenario Figure 8-17	 <p>Switch 1 and Switch 2 form a VSU system. Modify the device ID of Switch 2 to 3 and its priority to 150. Assume that Switch 1 is the global master switch and perform the configuration on the global master switch.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Modify the configurations of Switch 2.
Switch-1	<pre>Nodexon#config Nodexon(config)# switch virtual domain 100</pre>

```

!
switch 3 description switch-3
!

```

8.4.2.2 Configuring the VSL

Configuration Effect

When switches form a VSU system or when the VSU system is running, you can shift between common interfaces and VSL interfaces. However, you can only log in to the master device console of the VSU system for modification, but cannot enter the global configuration mode from the slave device console.

Notes

- You can log in to the console of the VSU system by using a serial port or telnet, in order to add or delete the configurations of VSL member interfaces.
- To prevent incorrect connections in actual scenarios, the VSL AP uses dynamic negotiation. You need to configure the VSL interface pool first, and then add the VSL interface pool to the same AP after successful negotiation. Interfaces connecting to the same device are within the same AP.

Configuration Steps

↘ Entering the VSL Interface Configuration mode

- Run the **vsl-port** command to enter the VSL-PORT configuration mode. This command is optional.
- When the device enters the VSL-PORT configuration mode, the VSL interface can be configured or deleted.

Command	vsl-port
Parameter	N/A
Description	
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command in the standalone or VSU mode.

↘ Configuring a VSL Member Interface

- Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add a VSL interface. This command is optional.
- Run the **port-member interface** command to configure a VSL member interface.

Command	port-member interface <i>interface-name</i> [copper fiber]
Parameter	<i>interface-name</i> : Indicates a two-dimensional interface name, such as GigabitEthernet 0/1 and GigabitEthernet 0/3.
Description	copper : Indicates the copper interface attribute.

	fiber: Indicates the optical interface attribute.
Defaults	N/A
Command Mode	VSL interface configuration mode
Usage Guide	You can run this command in the VSU mode or standalone mode. The command can take effect after the command configuration is saved and the device where the VSL member interface resides is restarted.

During the VSU system running, the configured VSL member links take effect immediately. VSL interfaces need to be configured for all devices.

For some devices, VSL interfaces must be optical interfaces of 10 Gigabit or higher; for cassette devices, VSL interfaces can be optical and copper interfaces of Gigabit or higher.

Modules on devices must be modules of 10 Gigabit or higher.

40G one-to-four interfaces cannot be configured as VSL interfaces.

-  For a 40G port (no matter whether splitting is performed for the interface), its member interfaces (namely, four 10G interfaces) cannot be shifted to VSL member interfaces.
-  If an interface has been configured as an NLB reflex interface, this interface can be shifted to a VSL member interface only after the NLB reflex interface configuration is deleted.
-  To prevent a loop that may occur when a VSL member interface exits from the VSL AP, the system automatically sets the member interface to the shutdown state when the command is executed to make the VSL member interface exit from the VSL AP. After the VSL member interface exits from the VSL AP, you can reconnect the link and run the **no shutdown** command to enable this interface again. When you configure a VSL interface, the system will shut it down first. If the configuration fails and you want to use it as a common interface, you can run the **no shutdown** command to enable this interface again. Add a member interface number that must be a three-dimensional interface number. For example, in the VSL-PORT configuration mode, if you run the **port-member interface** Tengigabitethernet 1/1/1 command, it indicates that you configure the global three-dimensional interface 1/1/1 as a VSL interface.
-  If VSU topology splitting occurs when you change a VSL interface to a common interface, the VSL interface cannot be deleted. You can disconnect the physical interface first and then delete the VSL interface.

Verification

- Use the `show switch virtual link [port]` to display the current VSL link running information in the VSU mode.

Command	show switch virtual link [port]
Parameter Description	port: Displays the status information of the VSL member interfaces.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the VSL

<p>Scenario Figure 8-18</p>	
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Add interface 1/1/3 as the VSL interface for Switch 1 and delete interface 1/1/2 from the VSL interface.
<p>Switch-1</p>	<pre>Nodexon#config Nodexon(config)# vsl-port Nodexon(config-vsl-port)# port-member interface Tengigabitethernet 1/1/3 Nodexon(config-vsl-port)# no port-member interface Tengigabitethernet 1/1/2</pre>
<p>Verification</p>	<ul style="list-style-type: none"> ● Run the show switch virtual config command to view the VSL. Assume that Switch 1 is the global master switch and run the command on the global master switch.
<p>Switch-1</p>	<pre>Nodexon#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) ! switch virtual domain 100 ! switch 1 switch 1 priority 100 ! switch convert mode virtual ! port-member interface Tengigabitethernet 1/1 ! port-member interface Tengigabitethernet 1/3 !</pre>

!
```

8.4.2.3 Configuring Dual-Active Detection

Configuration Effect

Configure the relevant detection mechanism to prevent the dual-active is being generated.

Notes

- The DAD can be configured only in the VSU mode. You are not allowed to configure the DAD mechanism in the standalone mode.
- All DAD configurations will take effect immediately after being configured on the master or slave devices in global configuration mode by running the **show running-config** command.
- The BFD-detected configuration information can be displayed only by running the dual-active detection display command rather than the BFD display command.

Configuration Steps

↘ Configuring the BFD DAD

- The BFD DAD requires establishing a directly connected link between two switches. The interfaces on the two ends must be physical routing interfaces. The following configuration must be performed on both device.
- Enter the interface configuration mode of the DAD interface and configure the DAD interface as a routing interface.
- After exiting from the interface configuration mode, run the **switch virtual domain *domain_id*** command to enter the domain configuration mode.
- In the domain mode, run the **dual-active detection bfd** command to enable BFD. This command is optional and can be used when BFD DAD needs to be configured.

- In the domain configuration mode, run the **dual-active bfd interface** *interface-name* command to configure the BFD DAD interface. This command is optional and can be used to configure the BFD DAD interface when BFD DAD is configured.
- Delete the BFD DAD interface. If no BFD DAD interface is available, BFD detection cannot be used.

Command	switch virtual domain <i>domain_id</i>
Parameter	<i>domain_id</i> : Indicates the domain ID.
Description	
Defaults	The default domain ID is 100.
Command Mode	Global configuration mode
Usage Guide	Only two devices with the same domain ID can form a VSU system. The domain ID must be unique on a LAN.

Command	dual-active detection { aggregateport bfd }
Parameter	Aggregateport : Specifies the AP detection mode.
Description	bfd : Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode.

Command	dual-active bfd interface <i>interface-name</i>
Parameter	<i>interface-name</i> : Indicates the interface type and ID.
Description	
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	A BFD DAD interface must be a routing interface and on different switches.

The BFD detection interfaces must be directly connected physical routing ports. The two ports must be on different devices.

The interface type is not limited. The dual-active detection link is only used to transmit BFD packets with a small amount of traffic. Therefore, you are advised to adopt the Gigabit interface or 100 M interface as the dual-active detection interface.

After the layer 3 routing interface that is configured with two master devices is converted into a layer 2 switch interface (run the switchport command under this interface), the BFD dual-active detection will be cleared automatically.

You are advised to directly connect BFD detection interfaces only to the master and slave devices.

 When the VSU system detects dual-active conflict and brings another VSU group to the recovery state, you can resolve the problem only by rectifying the VSL fault, but not directly restoring the VSU group in the recovery state; otherwise, dual-active conflict may be caused on the network.

↘ **Configuring the AP-based DAD**

- To configure the AP-based DAD, you must configure an aggregate port (AP) first and then specify the AP port as the DAD interface.
- Run the **port-group** *ap-num* command to add a physical member interface to the AP.
- After entering the domain configuration mode, run the **dual-active detection aggregateport** command to enable AP detection mode. This command is optional. You can run this command when AP detection needs to be configured.
- Run the **dual-active interface** *interface-name* command to configure the AP as the DAD interface. This command is optional. You can run this command to configure the AP as the DAD interface when AP detection needs to be configured.
- Run the **dad relay enable** command to enable dual-active detection packet relay for upstream and downstream interfaces. This command is optional. You can run this command to relay DAD packets (dual-active detection packets) when AP-based DAD is configured.
- Disabling AP-based DAD will inactivate DAD.
- Delete the detected interface. If no AP-based DAD interface is available, AP-based DAD cannot be used.
- The AP-based DAD packet relay is disabled by default.

Command	dual-active detection { aggregateport bfd }
Parameter	aggregateport: Specifies the AP detection mode.
Description	bfd: Specifies the BFD detection mode.
Defaults	The DAD is disabled.
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode.

Command	dual-active interface <i>interface-name</i>
Parameter Description	<i>interface-name:</i> Indicates the interface type and interface ID. An AP-based DAD interface must be specified.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Only one AP-based DAD interface can be configured. This interface must be created before you configure an AP as a DAD interface. Subsequently configured DAD interfaces will overwrite the previous ones.

Command	dad relay enable
Parameter Description	N/A
Defaults	The AP-based DAD packet relay is disabled by default.
Command	Interface configuration mode

Mode	
Usage Guide	This command can only be executed on the AP.

-  You are advised to distribute the physical interfaces that are added to the AP-based detection interface to different devices.

↘ **Configuring the excluded interface in the recovery mode**

- When two master devices are detected, one of them must enter the recovery mode. In the recovery mode, you need to disable all service interfaces. For some special usages (for example, configuring a management switch from which you can log in to a remote interface), you can set some ports to excluded interfaces that are not disabled in the recovery mode.
- In the domain configuration mode, run the **dual-active exclude interface** *interface-name* command to specify an excluded interface that will not be disabled in the recovery mode. This command is optional.

Command	dual-active exclude interface <i>interface-name</i>
Parameter Description	<i>interface-name</i> : Indicates the interface type and interface ID.
Defaults	N/A
Command Mode	Domain configuration mode
Usage Guide	Configure this command only in the VSU mode. An excluded interface must be a routing interface instead of a VSL interface. You can configure multiple excluded interfaces.

-  The excluded interface must be routing rather than VSL.
-  After the excluded interface is converted from a routing one into a switch interface (run the **switchport** command under this interface), the configurations of the excluded interface that is associated with this interface will be cleared automatically.

Verification

Use the **show switch virtual dual-active { aggregateport | bfd | summary }** to display the current DAD configuration.

Command	show switch virtual dual-active { aggregateport bfd summary }
Parameter Description	aggregateport : Displays DAD information on the AP. bfd : Displays BFD-based DAD information. summary : Displays DAD summary.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

↘ **Configuring the BFD DAD**

Scenario
Figure 8-19

- Switch 1 and Switch 2 form a VSU (The domain ID is 1) system. The priorities of Switch 1 and Switch 2 are 200 and 150 respectively. The links between Te1/3/1 and Te1/3/2 of Switch 1 and Te2/3/1 and Te2/3/2 of Switch 2 are established respectively to form a VSL between Switch 1 and Switch 2. The G0/1, G0/2, G0/3 and G0/4 interfaces of Switch A are connected to G1/1/1 and G1/2/1 of Switch 1 and G2/1/1 and G2/2/1 of Switch 2 to form an AP group including four member links. The ID of the AP group is 1. All members of AP group 1 are Gigabit optical interfaces. G1/1/2 and G2/1/2 are routing interfaces.
- G1/1/2 and G2/1/2 are a pair of BFD DAD interfaces.

Configuration Steps

- Configure G1/1/2 and G2/1/2 as routing interfaces.
- Enable the BFD DAD.
- Configure G1/1/2 and G2/1/2 as BFD DAD interfaces.

Since Switch 1 and Switch 2 are in a VSU system, the preceding configuration can be performed on either Switch 1 or Switch 2. on the following example configures the functions on Switch 1.

Switch 1

```
Nodexon(config)# interface GigabitEthernet 1/1/2
Nodexon(config-if-GigabitEthernet 1/1/2)# no switchport
Nodexon(config)# interface GigabitEthernet 2/1/2
Nodexon(config-if-GigabitEthernet 2/1/2)# no switchport
Nodexon(config-if)# switch virtual domain 1
Nodexon(c config-vs-domain)# dual-active detection bfd
Nodexon(config-vs-domain)# dual-active bfd interface GigabitEthernet
1/1/2
Nodexon(config-vs-domain)# dual-active bfd interface GigabitEthernet
```

Switch A

```
Nodexon# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Nodexon(config)# interface aggregateport 1
```

↘ Configuring the AP LFF mode

- In the domain configuration mode, run the **switch virtual aggregateport-lff enable** command to enable the AP LFF mode. This command is optional.
- The member ports of AP can be distributed on two device of the VSU system. You can configure whether the AP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the AP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual aggregateport-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode
Usage Guide	Enable the AP LFF in the VSU mode.

↘ Configuring the ECMP LFF mode

- In the domain configuration mode, run the **switch virtual ecmp-lff enable** command to enable the ECMP LFF mode. This command is optional.
- The Equal-Cost MultiPath (ECMP) routing egress can be distributed on two device of the VSU system. You can configure whether the ECMP egress traffic is forwarded through local member ports first based on actual traffic conditions.
- If this function is disabled, traffic is forwarded based on the ECMP configuration rules. For details, see the *Configuring Aggregate Port*.

Command	switch virtual ecmp-lff enable
Parameter	N/A
Description	
Defaults	This function is enabled by default.
Command Mode	Domain configuration mode
Usage Guide	Enable the ECMP LFF in the VSU mode.

 In the VSU mode, the across-device AP LFF mode and the ECMP LFF mode are disabled by default.

 To deploy a VSU system for layer-3 switches, you are advised to configure the IP-based AP load balancing (src-ip, dst-ip and src-dst-ip).

Verification

Use the **show switch virtual balance** command to display the current traffic balancing mode of the VSU system.

Command	show switch virtual balance
----------------	------------------------------------

Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the configuration of the traffic balancing mode in the VSU mode.

Configuration Example

Configuring the LFF

Scenario Figure 8-20	
	In Figure 8-20, Switch 1 and Switch 2 form a VSU system. It is assumed that Switch 1 is the global master switch and configuration is performed on Switch 1.
Configuration Steps	<ul style="list-style-type: none"> Configure the AP LFF.
Switch-1	<pre>Nodexon#config Nodexon(config)# switch virtual domain 100 Nodexon(config-vs-domain)# switch virtual aggregateport-lff enable</pre>
Verification	<ul style="list-style-type: none"> Run the show switch virtual balance command for verification.
Switch-1	<pre>Nodexon#show switch virtual balance Aggregate port LFF: enable Ecmp lff enable</pre>

8.4.2.5 Changing the VSU Mode to the Standalone Mode

Configuration Effect

Dismiss the VSU system into individual devices that can operate in the standalone mode.

Configuration Steps

- Run the **switch convert mode standalone** [*switch_id*] command to change the VSU mode to the standalone mode. This command is optional.
- After you run this command, the system will prompt you as follows: Whether to restore the configuration file to standalone text? If **yes**, the configuration file will be restored; if **no**, the configuration of virtual device mode will be cleared.

Command	switch convert mode standalone [<i>switch_id</i>]
Parameter Description	<i>switch_id</i> : Indicates the switch ID.
Defaults	The switch is in the standalone mode by default.
Command Mode	Privileged EXEC mode
Usage Guide	<p>After you run the switch convert mode standalone command, the master switch backs up the global configuration files of all VSDs in the VSU mode as <i>vsd.virtual_switch.text.vsd</i> ID. Then, the master switch clears the global configuration files <i>config.text</i> of all VSDs in the VSU mode, and asks you whether to overwrite the global configuration files <i>config.text</i> with <i>vsd.standalone.text.vsd</i> ID. If you select yes, the content of <i>vsd.standalone.text.vsd</i> ID will overwrite the global configuration file <i>config.text</i> of all VSDs; otherwise, the master switch does not recover <i>config.text</i>. Finally, restart the switch.</p> <p>This command can be used in the standalone mode or VSU mode. If the command is executed in the standalone mode, the mode switching is performed on the current switch. If the command contains the <i>sw_id</i> parameter and is executed in the VSU mode, the mode switching is performed on the switch with the ID specified by <i>sw_id</i>. If the command does not contain the <i>sw_id</i> parameter, the mode switching is performed on the master switch. You are advised to switch the mode of the slave switch and then that of the master switch.</p>

Configuration Example

Changing the VSU Mode to the Standalone Mode

Scenario Figure 8-21	 <p>In Figure 8-21, it is assumed that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master switch.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Change the mode of Switch 1 to the standalone mode. ● Change the mode of Switch 2 to the standalone mode.
Switch-1	<pre>Nodexon# switch convert mode standalone 1</pre> <pre>Nodexon# switch convert mode standalone 2</pre>
Verification	Run the show switch virtual config command to display the switch status.
Switch-1	<pre>Nodexon#show switch virtual config switch_id: 1 (mac: 0x1201aeda0M) !</pre>

```
switch virtual domain 100
!
switch 1
switch 1 priority 100
!
switch convert mode standalone
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/3
!
```

```
switch_id: 2 (mac: 0x1201aeda0E)
!
switch virtual domain 100
!
switch 2
switch 2 priority 150
!
switch convert mode standalone
!
port-member interface Tengigabitethernet 1/1
!
port-member interface Tengigabitethernet 1/2
!
switch 2 description switch-2
!
```

8.4.3 Configuring Quick Blinking Location

Configuration Effect

- Enable quick blinking location of a switch to make the status LED of the switch quickly blink.

Notes

If you do not disable quick blinking location, the system automatically disables the function 30 minutes after it is enabled.

Configuration Steps

▾ Enabling/Disabling quick blinking location

- Mandatory. Use this function on a switch that needs to be located.
- In the privileged EXEC mode, run the **led-blink** command to enable quick blinking location.

Command	led-blink { enable disable } [device <i>device_id</i>]
Parameter	enable : Enables quick blinking location.
Description	disable : Disables quick blinking location. <i>device_id</i> : Indicates the device ID.
Defaults	Quick blinking location is disabled by default.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command without the <i>device_id</i> parameter to enable or disable the quick blinking search in the standalone mode. In the VSU mode, you can set the <i>device_id</i> parameter to enable or disable this function for a specified device. If you ignore the device_id parameter, you can enable or disable this function for all devices in the VSU system. If you do not disable this function, the system automatically disables the function 30 minutes after it is enabled. This configuration cannot be saved. Quick blinking location will be disabled upon restart or failover.

Verification

- Check whether the status LED of a switch quickly blinks.

Configuration Example

▾ Enabling quick blinking location for the two VSU devices

Scenario	Assume that Switch 1 and Switch 2 form a VSU system and Switch 1 is the global master device.
Configuration Steps	<ul style="list-style-type: none"> ● Enter the led-blink enable device 2 command on the Switch 1 console to enable quick blinking location. ● Enter the led-blink disable device 2 command on the Switch 1 console to disable quick blinking location.
Verification	When quick blinking location is enabled, check whether the status LED of Switch 2 quickly blinks.

8.5 Monitoring

Displaying

Description	Command
Displays the current VSU operation, topology or configuration.	show switch virtual [topology config role]
Displays the current dual-active configuration.	show switch virtual dual-active { bfd aggregateport summary }
Displays the current VSL running information in the VSU mode.	show switch virtual link [port]
Displays the current switch ID.	show switch id

9 Configuring RNS

9.1 Overview

The reliable network service (RNS) tests specific services provided by a peer device to monitor the service availability, integrity of the end-to-end connection, and service quality. Using the RNS test results, you can:

- Learn the network performance in time and take measures accordingly to handle related network performance problems.
- Diagnose and locate network faults.

9.2 Applications

9.2.1 Testing and Evaluating Service Performance

Scenario

As shown in the following figure, a company is going to deploy a video conference system between the headquarters and branches, and has completed the related quality of service (QoS) configurations. Before formal deployment, it must be checked whether the services can be provisioned normally under the existing service pressure of the company. The video conference system is sensitive to the User Datagram Protocol (UDP) delay and UDP transmission jitter of the network. The traditional ping tool can test the Internet Control Message Protocol (ICMP) performance, but cannot effectively evaluate the UDP transmission performance and cannot meet the requirement for jitter measurement.

Remarks	A, B, and C are switches.
----------------	---------------------------

Deployment

- Configure RNS on the egress switching device or switch of each branch to test the UDP jitter and delay.

- On Switch A, specify the IP address and UDP port of the egress switching device or switch in the headquarters, and then UDP packets can be automatically sent. Based on the configurations, the egress switching device or switch in the headquarters can automatically respond to the UDP packets. The egress switching device or switch of the branch processes the sent and received packets, and calculates the UDP jitter. To learn the performance in different periods of time, you also need to configure scheduling functions, such as periodically start/stop and repeated running, for the RNS.

9.2.2 Locating Network Faults

Scenario

On the campus network as shown in Figure 9-1, Student 1 reports a Web server access failure, Student 3 reports an Internet access failure, and Student 6 reports an email sending/receiving failure.

Figure 9-1

Deployment

- The administrator directly enables the DNS function on the access switch of the dormitories to test whether the domain name service (DNS) server is faulty. If DNS fails, an ICMP echo packet is automatically triggered to test whether the Web server is reachable.
- When a fault occurs, the administrator only needs to start a test, and the subsequent tests can be automatically triggered. Then, the administrator can check the test results to locate the fault, which greatly reduces the workload for the administrator.

9.3 Features

Basic Concepts

↳ RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure the RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

Feature	Description
RNS Instance	Monitor the network connectivity, service availability, integrity of end-to-end connection, and service quality.
Track Support for the RNS	Track the test results and notify the related module of the results.

9.3.1 RNS Test

Monitor the network connectivity, service availability, integrity of end-to-end connection, and service quality. For example, test whether the DNS function of the device is normal. Currently, the RNS supports the following types of tests: ICMP echo, DNS, and TCP.

Working Principle

↳ ICMP Echo Test

ICMP echo is a basic function of the RNS, and is implemented in compliance with the RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

An ICMP echo request packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the ICMP echo request packet, an ICMP echo reply packet is returned from the destination IP address. Through the ICMP echo test, the response time and packet loss rate is calculated based on the information relating to the received ICMP echo reply packet, for example, the receipt time and number of packets. In this way, the current network performance and status are reflected. The ICMP echo test results and historical records will be recorded, and you can use the command line to display them.

 The prerequisite for a successful ICMP echo test is that destination devices can correctly respond to ICMP echo request packets.

↳ DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, and the mapping between the resolved domain name and the IP address is not saved. The DNS test results and

historical records will be recorded in the test group. You can use the command line to check the test results and historical records.

📄 Procedure for Configuring an RNS Instance Test

1. Create an instance and configure the test based on the test type.
2. Start the instance.
3. Use the RNS instance to construct a packet of the specific test type and send the packet to the peer end.
4. Upon receipt of the test packet, the peer end returns a reply packet of a corresponding type.
5. The RNS instance calculates the packet loss rate and round trip time based on whether a reply packet is received and the time of reply packet receipt.
6. Use the show or debug command to check the test result.

i The preceding describes general procedures for RNS instance tests. For details about configuration, see the following sections.

Related Configuration

📄 Configuring the Test Repeat Interval

By default, the test repeat interval is 60s.

In RNS configuration mode, run the **frequency** *millisecond* command to configure the test repeat interval.

Configure the frequency based on the following formula to ensure correct test calculation.

(frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

📄 Configuring the Test Timeout

The default timeout varies according to the test type. You can run the **show ip rns configuration** command to display the timeout of a specific test type.

In RNS configuration mode, run the **timeout** *milliseconds* command to configure the timeout of an instance.

Configure the timeout based on a formula. For details, see the "Usage Guide" of the **frequency** command.

Configure the test time threshold.

📄 Configuring the Test Threshold

By default, the test threshold is 5,000 ms.

In RNS configuration mode, run the **threshold** *milliseconds* command to configure the instance test threshold.

Configure the threshold based on a formula. For details, see the "Usage Guide" of the **frequency** command.

📄 Configuring a Tag for the Test

No default configuration is available.

In RNS configuration mode, run the **tag** *text* command to configure a test tag.

You can run the **tag** command to specify a tag to identify the test.

📌 Configuring the Protocol Payload Size

The default protocol payload size varies with the test type. By default, the protocol payload size is the minimum or appropriate size for protocol packets of the corresponding test type.

In RNS configuration mode, run the **request-data-size bytes** command to configure the protocol payload size.

Perform this configuration in IP RNS configuration mode.

📌 Configuring the TOS Field of the Test Packet

By default, the TOS is 0.

In RNS configuration mode, run the **tos number** command to configure the TOS field in the IPv4 header of RNS test packets.

📌 Configuring the VRF

No default configuration is available.

In RNS configuration mode, run the **vrf vrf-name** command to virtual routing and forwarding (VRF) for the RNS instance.

9.3.2 Track Support for the RNS

Objects that can be tracked include: test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of other modules is triggered.

Working Principle

The test result of an RNS instance is tracked as follows:

- Configure a track object for tracking the test result of an RNS instance.
- When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.
- The track module receives the test result. After the preset delay, if the test result remains unchanged, the status of the track object is modified, and the module of the track object is notified of the modification. If the test result recovers within the period, the status of the track object is not modified and the corresponding module is not notified.

Related Configuration

📌 Configuring a Track Object for Tracking the Link Status of An Interface

By default, the function of tracking the link status of an interface is disabled.

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

If the link status of the interface is UP, the status of the track object is UP. If the link status of the interface is DOWN, the status of the track object is also DOWN.

📌 Configuring a Track Object for Tracking the Test Result of an RNS Instance

By default, the function of tracking the test result of an RNS instance is disabled.

Run the **track rns** command to configure a track object, which is used to track the test result of an RNS instance. The RNS instance ID ranges from 1 to 500.

If the RNS test succeeded, the track object is in Up state. If the RNS test failed, the track object is in Down state.

▾ [Configuring a Track Object for Tracking the Status of a Track List](#)

By default, the function of tracking the status of a track list is disabled.

Run the **track list** command to configure a track object, which is used to track the status of a track list. The result can be the AND or OR operation result of all member status.

If the result of this track object is set to the OR operation result of all member status, when all RNS tests succeeded, the track object is in Up state. If one RNS test failed, the track object is in Down state. If the result of this track object is set to the AND operation result of all member status, when all RNS tests failed, the track object is in Down state. If one RNS test succeeded, the track object is in Up state.

▾ [Configuring a Track List Member](#)

By default, no member is configured for the track list.

Run the **object** command to configure a track list member. The status of the member can be the same as or contrary to that of the corresponding track object.

▾ [Adjusting the Delay for Notifying the Status Change of a Track Object](#)

By default, the delay for notifying the status change of a track object is 0.

Run the **delay** command to adjust the delay for track notification, including the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. The delay ranges from 0 to 180. The unit is second.

A longer delay indicates that it takes more time before the module that is concerned with the track object is notified of the status. A shorter delay indicates that it takes less time before the module that is concerned with the track object is notified of the status.

9.4 Configuration

Configuration Item	Description and Command
Configuring RNS Basic	 (Mandatory) It is used to configure basic function parameters of the RNS.

Configuration Item	Description and Command	
Functions	ip rns	Supports detailed configuration and brief configuration. <ul style="list-style-type: none"> Detailed configuration: An RNS operation object is defined, and used as the configuration ID for subsequent tests and parameters. Brief configuration: Subsequent configuration is not required, and tests can be started in one step. Currently, ICMP echo, DNS, and TCP tests can be started in one step.
	ip rns reaction-configuration	Configures the proactive threshold monitoring and triggering mechanism of the RNS test.
	ip rns reaction-trigger	Triggers another type of the RNS test in pending state when the monitoring threshold exceeds the expectation during an RNS test.
	ip rns schedule	Configures the scheduling method, start time, and life time of an RNS test.
	ip rns restart	Restarts an RNS test.
	ip rns reset	Clears all the IP RNS configurations.
Configuring the ICMP Echo Test	 (Optional) It is used to implement the ICMP echo test.	
	icmp-echo	Creates an ICMP echo test instance.
	request-data-size	Configures the protocol payload size.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the IPv4 header of test packets.
Configuring the DNS Test	 (Optional) It is used to implement the DNS test.	
	dns	Creates a DNS test instance.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the TOS field in the IPv4 header of test packets.
Configuring the Track	 (Optional) It is used to configure the track support for other test modules.	

Configuration Item	Description and Command	
Support for the RNS	track rns	Configures a track object for tracking the test result of an RNS instance.
	track interface line-protocol	Configures a track object for tracking the link status of an interface.
	track list	Configures a track object for tracking the status of a track list.
	object	Configures a member object for a track list object.
	delay	Configures the delay for notifying the status change of a track object.

9.4.1 Configuring RNS Basic Functions

Configuration Effect

- Detailed configuration: Configures an RNS instance to complete basic configuration of the RNS instance.
- Brief configuration: Configure and start an RNS instance at a time. (Optional)

Notes

- In detailed configuration mode, if you do not configure the test type after entering the IP RNS mode by running the command, the RNS instance will not be created.
- In detailed configuration mode, after configuring an RNS instance, you need to run the **ip rns schedule** command to configure the startup policy; otherwise, the test will not be implemented.

Configuration Steps

▾ Defining an RNS Operation Object

- Mandatory.
- Unless otherwise required, define an RNS operation object on each switch.
- Brief configuration is optional.

▾ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for an RNS Test

- Perform this configuration if it is required to configure the proactive threshold monitoring and triggering mechanism for the test.
- Perform this configuration on every switching device unless otherwise required.

▾ Enabling an RNS Instance to Trigger Another RNS Instance

- Perform this configuration if it is required to trigger another RNS test in pending state when the monitoring threshold exceeds the expectation during an RNS test.
- If schedule parameters are not configured for the triggered RNS instance, the default schedule parameters are applied.

- Unless otherwise required, apply this configuration to each switch.

↘ Configuring Schedule Parameters of an RNS Instance

- Perform this configuration on every switching device unless otherwise required.
- In the case of brief configuration, this command is already configured using the default values, and manual configuration is not required.

↘ Restarting an RNS Instance

- Perform this configuration, or directly run the **ip rns schedule X start-time now** command if it is required to restart an IP RNS instance in pending state.

↘ Clearing Configurations of All RNS Instances

- Perform this configuration if it is required to clear configurations of all the IP RNS instances, for example, when a lot of instances are configured but configurations are found incorrect.

Verification

- Run the **show ip rns configuration** command to display configurations of RNS instances.

Related Commands

↘ Defining an IP RNS Operation Object

Command	ip rns <i>operation-number</i>
Parameter Description	<i>operation-number</i> . Indicates the RNS instance ID. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	<p>Currently, the RNS supports only IPv4-related tests, but not IPv6-related tests. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporary disabled to ensure normal operation of core services, such as route forwarding.</p> <p>Detailed configuration (executing mandatory items of ip rns <i>operation-number</i>): Run this command and enter the IP-RNS configuration mode. In this mode, you can define various test types. If the test type is not configured, the RNS test is not created. After configuring an RNS test, you must run the ip rns schedule command to configure its schedule parameters; otherwise, the test cannot be conducted.</p> <p>After configuring the type of an RNS test, you can run the ip rns command to enter the mode of the test type. To modify the type of an RNS instance, you need to first delete the RNS instance by running the no ip rns command in global configuration mode.</p>

↘ Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

Command	ip rns reaction-configuration <i>operation-number</i> react <i>monitored-element</i> [action-type]
----------------	---

	<p><i>option</i>][threshold-type {average [<i>number-of-measurements</i>] consecutive [<i>occurrences</i>] immediate never xofy [<i>x-value y-value</i>] }] [threshold-value <i>upper-threshold lower-threshold</i>]</p>																		
Parameter Description	<p><i>operation-number</i>: Indicates the RNS instance ID. The value ranges from 1 to 500.</p> <p><i>monitored-element</i>: Specifies the monitored element.</p> <p>action-type <i>option</i>: Indicates the action taken after the test is triggered.</p> <p>average [<i>number-of-measurements</i>]: Indicates that the subsequent associated actions are triggered if the average of <i>number-of-measurements</i> of the monitored element exceeds the threshold.</p> <p>consecutive [<i>occurrences</i>]: Indicates that the test is triggered if the consecutive number of <i>occurrences</i> of the monitored element exceeds the threshold. The default value of <i>occurrences</i> is 5. The value ranges from 1 to 16.</p> <p>immediate: Indicates that the test is triggered immediately after the monitored element exceeds the threshold.</p> <p>never: Indicates that the test is never triggered.</p> <p>xofy [<i>x-value y-value</i>]: Indicates that results of X tests exceed the threshold in the last Y tests. The default values of X and Y are 5. The value of X or Y ranges from 1 to 16.</p> <p>threshold-value <i>upper-threshold lower-threshold</i>: Indicate the upper and lower thresholds.</p> <ul style="list-style-type: none"> When monitored-element is rtt, the thresholds are the time. For default values, see "Usage Guide". The value ranges from 0 to 60,000 ms. Note that you do not need to configure threshold-value when react is set to timeout. 																		
Command Mode	Global configuration mode																		
Usage Guide	<p>You can configure multiple thresholds for one RNS test to monitor different elements. The following table provides the mapping between test types and monitored elements.</p> <table border="1"> <tr> <td>monitored-element</td> <td>icmp-echo</td> <td>dns</td> </tr> <tr> <td>timeout</td> <td>✓</td> <td>✓</td> </tr> <tr> <td>rtt</td> <td>✓</td> <td>✓</td> </tr> </table> <p>The following table lists the default thresholds of each monitored element.</p> <table border="1"> <thead> <tr> <th>Monitored Element</th> <th>Upper Threshold</th> <th>Lower Threshold</th> </tr> </thead> <tbody> <tr> <td>timeout</td> <td>-</td> <td>-</td> </tr> <tr> <td>rtt</td> <td>5000ms</td> <td>0ms</td> </tr> </tbody> </table>	monitored-element	icmp-echo	dns	timeout	✓	✓	rtt	✓	✓	Monitored Element	Upper Threshold	Lower Threshold	timeout	-	-	rtt	5000ms	0ms
monitored-element	icmp-echo	dns																	
timeout	✓	✓																	
rtt	✓	✓																	
Monitored Element	Upper Threshold	Lower Threshold																	
timeout	-	-																	
rtt	5000ms	0ms																	

↘ **Enabling an RNS Instance to Trigger Another RNS Instance**

Command	ip rns reaction-trigger <i>operation-number target-operation</i>
Parameter	<i>operation-number</i> : Indicates the number of the source RNS instance that triggers the action. The value ranges from 1 to 500.

Description	<i>target-operation</i> : Indicates the number of the target RNS instance that is triggered. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	The trigger function is generally used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

📌 Configuring Schedule Parameters of an RNS Instance

Command	ip rns schedule <i>operation-number</i> [life { forever <i>seconds</i> }] [start-time { <i>hh:mm</i> [<i>:ss</i>] [<i>month day</i> <i>daymonth</i>] } pending now after <i>hh:mm:ss</i> }] [recurring]
Parameter Description	<p><i>operation-number</i>: Indicates the number of the RNS operation. The value ranges from 1 to 500.</p> <p>life forever: Indicates that the RNS operation life time is valid forever.</p> <p>life seconds: Indicates the running time of the RNS instance in seconds.</p> <p><i>hh:mm</i> [<i>:ss</i>]: Indicates the start time of the RNS instance, in 24-hour format.</p> <p><i>month</i>: Indicates the start month of the RNS instance. The default value is the current month.</p> <p><i>day</i>: Indicates the start date of the RNS instance. The default value is the current date.</p> <p>pending: Indicates that the start time of the RNS instance is not defined, which is the default.</p> <p>now: Indicates that the operation start time is now, that is, the operation starts now.</p> <p>after hh:mm:ss: Indicates that the RNS instance starts after a delay of hh:mm:ss.</p> <p>recurring: Indicates whether the RNS instance starts at the same time every day.</p>
Command Mode	Global configuration mode
Usage Guide	<p>If the schedule parameters of an RNS instance have been configured by running the ip rns schedule command, parameters cannot be modified during running. To modify the configuration, you need to run the no ip rns schedule command to delete the schedule parameters.</p> <p><i>life { seconds }</i> indicates the running time of the RNS instance. That is, the test stops after a period of time in seconds.</p>

📌 Restarting an RNS Test by Running the ip rns restart Command

Command	ip rns restart <i>operation-number</i>
Parameter Description	<i>operation-number</i> : Indicates the number of the RNS instance. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	<p>This command restarts an RNS test for which the scheduling policy is configured and is in pending state.</p> <p>This command is invalid for an RNS test for which the scheduling policy is not configured.</p>

📌 Clearing Configurations of All the IP RNS Instances by Running the ip rns reset Command

Command	ip rns reset
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command clears configurations of all the IP RNS instances. It is used only in extreme cases, for example, when a lot of RNS tests are configured but the configurations are found incorrect.

Configuration Example

Configuring RNS Basic Functions

Scenario Figure 9-2	<p>The diagram illustrates a network topology for RNS configuration. On the left, 'RNS Client' is represented by 'Switch A' with a circular icon. A line connects it to a central cloud labeled 'ISP'. Another line connects the 'ISP' cloud to 'Switch B' on the right, which is labeled 'RNS Server'. Above the line between Switch A and the ISP, the IP address '10.1.1.1/16' is written. Above the line between the ISP and Switch B, the IP address '10.2.2.2/16' is written.</p>
Configuration Steps	<ul style="list-style-type: none"> ● Configure instance 1 on Switch A. ● Configure the scheduling method, start time, and life time of instance 1. ● Configure the proactive threshold monitoring and triggering mechanism of instance 1. ● Trigger instance 2 in pending state when the monitoring threshold of instance 1 exceeds the expectation.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.1.1.1 A(config-ip-rns-icmp-echo)#exit A(config)ip rns schedule 1 start-time now life forever A(config)ip rns reaction-configuration 1 react timeout threshold-type immediate action-type trigger A(config)ip rns reaction-trigger 1 2</pre>
Verification	<p>Run the show ip rns configuration command to display the instance configurations.</p> <pre>Router#show ip rns configuration 1 Entry number: 1 Tag: ruijie555 Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000</pre>

```

Operation frequency (milliseconds): 60000
Threshold (milliseconds): 5000
Recurring (Starting Everyday): FALSE
Life (seconds): 3500
Next Scheduled Start Time:Start Time already passed
Target address/Source address: 2.2.2.3/0.0.0.0
Request size (ARR data portion): 36

```

9.4.2 Configuring the ICMP Echo Test

Configuration Effect

Create an ICMP echo test instance.

Notes

- The RNS basic functions must be configured.

Configuration Steps

▾ Creating an ICMP Echo Test Instance

- Mandatory.
- Unless otherwise required, create ICMP echo test instances on each switch.

▾ Configuring Common Optional Parameters of the Test

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and TOS, are required to be changed..
- Perform this configuration on every switching device unless otherwise required.

▾ Configuring the Protocol Payload Size

- Perform this configuration if it is required to change the protocol payload size of the test.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

▾ Creating an ICMP Echo Test Instance

Command	<code>icmp-echo { oob { destination-ip-address destination-hostname [name-server ip-address] }</code>
---------	---

	[source-ipaddr <i>ip-address</i>] via <i>type num</i> next-hop <i>ip-address</i> } { { <i>destination-ip-address</i> <i>destination-hostname</i> [name-server <i>ip-address</i>] } [source-ipaddr <i>ip-address</i>] [out-interface <i>type num</i> [next-hop <i>ip-address</i>]] }
Parameter Description	<p>oob: Indicates the test on the MGMT interface.</p> <p><i>destination-ip-address</i>: Indicates the destination IP address.</p> <p><i>destination-hostname</i>: Indicates the destination host name.</p> <p>name-server <i>ip-address</i>: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by using the ip name-server command is used for address resolution.</p> <p>source-ipaddr <i>ip-address</i>: Indicates the source IP address.</p> <p>out-interface <i>type num</i>: Specifies the outgoing interface (non-MGMT interface) of the test packet.</p> <p>via <i>type num</i>: Specifies the MGMT interface as the outgoing interface of the test packet.</p> <p>next-hop <i>A.B.C.D</i>: Indicates the IP address of the next hop.</p>
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After an ICMP echo test is started, the system sends an ICMP echo request packet to test whether the device is connected to the target host. After an ICMP-Echo test instance is created, the system enters the IP RNS ICMP echo mode. By default, the protocol payload size of an ICMP echo request packet is 36 bytes. You can run the request-data-size command to change the packet size. You need to configure the RNS test type (for example, ICMP echo and DNS) before configuring parameters. To modify the type of an RNS instance, you need to delete the RNS instance by running the no ip rns command in global configuration mode.

↘ Configuring the Protocol Payload Size of an RNS Instance

Command	request-data-size <i>bytes</i>
Parameter Description	<i>bytes</i> : Indicates the bytes of a test packet. The minimum and maximum bytes vary with the test type. You need to configure this parameter based on the command prompt in corresponding test mode.
Command Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command is used to stuff some bytes in the test packet so that large packets can be used for the test.

↘ Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)

Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the frequency command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)
--------------------	---

↘ Configuring a Tag for an RNS Instance

Command	tag <i>text</i>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

↘ Configuring the Time Threshold for an RNS Instance

Command	threshold <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the time threshold for the test. The value ranges from 0 to 60,000, in the unit of milliseconds. The default value is 5,000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configuring the Timeout for an RNS Instance

Command	timeout <i>millisecond</i>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configuring the TOS Field in the IPv4 Packet Header of an IP RNS Test

Command	tos <i>number</i>
Parameter	<i>number</i> : Sets the TOS field in the IPv4 header of test packets. The value ranges from 0 to 255. The default

Description	value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

📌 **Configuring the VRF of an RNS Test**

Command	<code>vrf vrf-name</code>
Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Figure 9-3	 <p>The diagram shows a network topology. On the left is 'Switch A' with IP address '10.1.1.1/16'. A line connects it to a central cloud labeled 'ISP'. Another line connects the 'ISP' cloud to 'Switch B' on the right, which has IP address '10.2.2.2/16'.</p>
	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)#icmp-echo 10.2.2.2 A(config-ip-rns-icmp-echo)#exit A(config)#ip rns schedule 1 start-time now life forever</pre>
	Run the show ip rns configuration command to display the instance configurations.

Switch A	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: icmp-echo Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): foerver Next Scheduled Start Time:Start Time already passed Target address/Source address: 10.2.2.2/0.0.0.0 Request size (ARR data portion): 36</pre>
-----------------	--

9.4.3 Configuring the DNS Test

Configuration Effect

Create a DNS test instance.

Notes

- The RNS basic functions must be configured.

Configuration Steps

↘ Creating a DNS Test Instance

- Mandatory.
- Unless otherwise required, create DNS test instances on each switch.

↘ Configuring Common Optional Parameters of the Test

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and TOS, are required to be changed.
- Perform this configuration on every switching device unless otherwise required.

Verification

- Run the **show ip rns configuration** command to display the instance configurations.

Related Commands

↘ Creating a DNS Test Instance

Command	<pre>dns { destination-hostname name-server ip-address [source-ipaddr ip-address] via type num next-hop ip-address }</pre>
----------------	--

Parameter Description	<i>destination-hostname</i> : Indicates the destination host name. name-server ip-address : Indicates the DNS IP address.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After a DNS test is started, the system sends a DNS parsing request packet to test whether the device is connected to the target host. After a DNS test instance is created, the system enters the IP RNS DNS mode. You need to configure the RNS test type before configuring parameters. To modify the type of an RNS instance, you need to delete the RNS instance by running the no ip rns command in global configuration mode.

▾ Configuring the Test Repeat Interval

Command	frequency <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the packet sending interval in ms. The default value is 60,000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the frequency command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

▾ Configuring a Tag for an RNS Instance

Command	tag <i>text</i>
Parameter Description	<i>text</i> : Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

▾ Configuring the Time Threshold for an RNS Instance

Command	threshold <i>milliseconds</i>
Parameter Description	<i>milliseconds</i> : Indicates the time threshold for the test. The value ranges from 0 to 60,000, in the unit of milliseconds. The default value is 5,000.
Command	IP RNS DNS configuration mode (config-ip-rns-dns)

Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configuring the Time Threshold for an RNS Instance

Command	timeout <i>millisecond</i>
Parameter Description	<i>millisecond</i> : Indicates the test timeout. The value ranges from 10 to 604,800,000. The unit is ms. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation. (frequency milliseconds) > (timeout milliseconds) >= (threshold milliseconds)

↘ Configures the TOS Field in the IPv4 Header of Test Packets

Command	tos <i>number</i>
Parameter Description	<i>number</i> : Sets the TOS field in the IPv4 header of test packets. The value ranges from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	TOS is a 8-bit field in the IPv4 packet header. By setting the TOS, you can control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate routers.

↘ Configuring the VRF of an RNS Test

Command	vrf <i>vrf-name</i>
Parameter Description	<i>vrf-name</i> : Specifies the VRF name.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies the VRF of the test packet.

Configuration Example

Scenario Figure 9-4	 <p>The diagram illustrates a network topology. On the left, a device labeled 'RNS Client' (Switch A) has an IP address of 10.1.1.1/16. This device is connected to a central cloud labeled 'ISP'. The ISP is connected to a device on the right labeled 'Dns server' with an IP address of 10.2.2.2/16.</p>
Configuration Steps	Configure RNS instance 1 and related parameters on Switch A.
Switch A	<pre>A# configure terminal A(config)# ip rns 1 A(config-ip-rns)# dns www.Nodexon.com.cn name-server 10.2.2.2 A(config-ip-rns-dns)#exit A(config)# ip rns schedule 1 start-time now life forever</pre>
Verification	Run the show ip rns configuration command to display the instance configurations.
Switch A	<pre>A#show ip rns configuration 1 Entry number: 1 Tag: Type of operation to perform: dns Operation timeout (milliseconds): 5000 Operation frequency (milliseconds): 60000 Threshold (milliseconds): 5000 Recurring (Starting Everyday): FALSE Life (seconds): forever Next Scheduled Start Time:Start Time already passed Target host name: www.Nodexon.com.cn Name Server: 10.2.2.2</pre>

Common Errors

- The DNS IP address is incorrect.

9.4.4 Configuring the Track Support for the RNS

Configuration Effect

- Configure the track function to track the test result of an RNS instance.
- Configure the track function to track the link status of an interface.
- Configure the track function to track the status of a track list.

- Configure the track function to track the status of an RNS list.

Notes

- To configure the track function to track the test result of an RNS instance, you need to configure the related RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the related interface.
- To configure the track function to track the status of a track list, you need to configure the members for the related track list.
- To configure the track function to track the status of an RNS list, you need to configure the members for the related RNS list.

Configuration Steps

▾ Configuring a Track Object

- Perform this operation if it is required to create a track object.
- The following four methods are available to create a track object:
 - Create a track object for tracking the test result of an RNS instance: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the link status of an interface: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of a track list: Perform this configuration on every switching device unless otherwise required.
 - Create a track object for tracking the status of an RNS list: Perform this configuration on every switching device unless otherwise required.

▾ Configuring the Notification Delay of a Track Object

- Perform this configuration if it is required to delay notification of the status change of a track object.
- Delay for notifying the status change of a track object includes the delay for notifying the status change of a track object from UP to DOWN and the delay for notifying the status change of a track object from DOWN to UP. You can configure either delay or both of delays.
- Perform this configuration on every switching device unless otherwise required.

▾ Configuring a Track Member

- Perform this configuration if it is required to configure a track object for tracking the status of a track list.
- When configuring a track member, you can set the status of a member meeting conditions to UP or DOWN.
- Perform this configuration on every switching device unless otherwise required.

Verification

Observe the status of a track object when the status of the track object (such as test results of an RNS instance, link status of an interface, or status of a track list) changes.

- After the preset delay, run the **show track** command to check whether the current track status changes.

Related Commands

▾ Configuring a Track Object for Tracking the Link Status of An Interface

Command	track <i>object-number</i> interface <i>interface-type interface-number</i> line-protocol
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	<i>Interface-type interface-number</i> : Indicates the interface type and interface number.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is UP, the status of the corresponding track object is UP.

▾ Configuring a Track Object for Tracking the Test Result of an RNS Test

Command	track <i>object-number</i> rns <i>entry-number</i>
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	<i>entry-number</i> : Indicates the number of an RNS instance. The value ranges from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the result of an RNS test. If the test succeeded, the track object is in Up state.

▾ Configuring a Track Object for Tracking the Status of a Track List

Command	track <i>object-number</i> list boolean { and or }
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of all member status.

▾ Configuring a Track Member

Command	object <i>object-number</i> [not]
Parameter	<i>object-number</i> : Indicates the number of a track object. The value ranges from 1 to 700.
Description	
Command Mode	Track configuration mode
Usage Guide	Run this command to configure a member for a track list. The number of track list members that can be configured is restricted only by the capacity of track objects.

9.5 Monitoring

Displaying

Description	Command
Displays configurations of one or more RNS instances.	show ip rns configuration [<i>operation-number</i>]
Displays detailed statistics of one or more RNS instances.	show ip rns collection-statistics [<i>operation-number</i>]
Displays the current RNS status.	show ip rns operational-state [<i>operation-number</i>]
Displays the proactive threshold monitoring information of one or more RNS instances.	show ip rns reaction-configuration [<i>operation-number</i>]
Displays information about the test triggered by one or more RNS instances.	show ip rns reaction-trigger [<i>operation-number</i>]
Displays the brief statistics of one or more RNS instances.	show ip rns statistics [<i>operation-number</i>]
Displays the brief statistics of one or more track objects.	show track [<i>object-number</i>]
Displays the brief statistics of a track client.	show track client

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs the track module.	debug track { <i>all</i> <i>proc-event</i> <i>rdnd-event</i> <i>client</i> }
Debugs the RNS module.	debug rns { <i>all</i> <i>interface</i> <i>lib</i> <i>rdnd-event</i> <i>restart</i> <i>rns_id</i> [0, 500]

1 Configuring SNMP

1.1 Overview

Simple Network Management Protocol (SNMP) became a network management standard RFC1157 in August 1988. At present, because many vendors support SNMP, SNMP has in fact become a network management standard and is applicable to the environment where systems of multiple vendors are interconnected. By using SNMP, the network administrator can implement basic functions such as information query for network nodes, network configuration, fault locating, capacity planning, and network monitoring and management.

📄 [SNMP Versions](#)

Currently, the following SNMP versions are supported:

- SNMPv1: The first official version of SNMP, which is defined in RFC1157.
- SNMPv2C: Community-based SNMPv2 management architecture, which is defined in RFC1901.
- SNMPv3: SNMPv3 provides the following security features by identifying and encrypting data.
 1. Ensuring that data is not tampered during transmission.
 2. Ensuring that data is transmitted from legal data sources.
 3. Encrypting packets and ensuring data confidentiality.

[Protocols and Standards](#)

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)

- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

1.2 Applications

Application	Description
Managing Network Devices Based on SNMP	Network devices are managed and monitored based on SNMP.

1.2.1 Managing Network Devices Based on SNMP

Scenario

Take the following figure as an example. Network device A is managed and monitored based on SNMP network manager.

Figure 1-1

Remarks	A is a network device that needs to be managed. PC is a network management station.
----------------	--

Deployment

The network management station is connected to the managed network devices. On the network management station, users access the Management Information Base (MIB) on the network devices through the SNMP network manager and receive messages actively sent by the network devices to manage and monitor the network devices.

1.3 Features

Basic Concepts

SNMP is an application layer protocol that works in C/S mode. It consists of three parts:

- SNMP network manager
- SNMP agent
- MIB

Figure 1-2 shows the relationship between the network management system (NMS) and the network management agent.

SNMP Network Manager

The SNMP network manager is a system that controls and monitors the network based on SNMP and is also called the NMS.

SNMP Agent

The SNMP agent (hereinafter referred to as the agent) is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also actively send messages to the NMS.

MIB

The MIB is a virtual network management information base. The managed network devices contain lots of information. To uniquely identify a specific management unit among SNMP packets, the MIB adopts the tree hierarchical structure. Nodes in the tree indicate specific management units. A string of digits may be used to uniquely identify a management unit system among network devices. The MIB is a collection of unit identifiers of network devices.

Figure 1-3 Tree Hierarchical Structure

↳ **Operation Types**

Six operation types are defined for information exchange between the NMS and the agent based on SNMP:

- Get-request: The NMS extracts one or more parameter values from the agent.
- Get-next-request: The NMS extracts the parameter value next to one or more parameters from the agent.
- Get-bulk: The NMS extracts a batch of parameter values from the agent.
- Set-request: The NMS sets one or more parameter values of the agent.
- Get-response: The agent returns one or more parameter values, which are the operations in response to the three operations performed by the agent on the NMS.
- Trap: The agent actively sends a message to notify the NMS of something that happens.

The first four packets are sent by the NMS to the agent and the last two packets are sent by the agent to the NMS. (Note: SNMPv1 does not support the Get-bulk operation.) Figure 1-4 describes the operations.

Figure 1-4 SNMP Packet Types

The three operations performed by the NMS on the agent and the response operations of the agent are based on UDP port 161. The trap operation performed by the agent is based on UDP port 162.

Overview

Feature	Description
Basic SNMP Functions	The SNMP agent is configured on network devices to implement basic functions such as information query for network nodes, network configuration, fault locating, and capacity planning.
SNMPv1 and SNMPv2C	SNMPv1 and SNMPv2C adopt the community-based security architecture, including authentication name and access permission.
SNMPv3	SNMPv3 redefines the SNMP architecture, namely, it enhances security functions, including the security model based on users and access control model based on views. The SNMPv3 architecture already includes all functions of SNMPv1 and SNMPv2C.

1.3.1 Basic SNMP Functions

Working Principle

Working Process

SNMP protocol interaction is response interaction (for exchange of packets, see Figure 1-4). The NMS actively sends requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. The agent receives the requests, completes operations, and returns a Get-response. Sometimes, the agent actively sends a trap message and an Inform message to the NMS. The NMS does not need to respond to the trap message but needs to return an Inform-response to the agent. Otherwise, the agent re-sends the Inform message.

Related Configuration

Shielding or Disabling the SNMP Agent

By default, the SNMP function is enabled.

The **no snmp-server** command is used to disable the SNMP agent.

The **no enable service snmp-agent** command is used to directly disable all SNMP services.

Setting Basic SNMP Parameters

By default, the system contact mode, system location, and device Network Element (NE) information are empty. The default serial number is 60FF60, the default maximum packet length is 1,572 bytes, and the default UDP port ID of the SNMP service is 161.

The **snmp-server contact** command is used to configure or delete the system contact mode.

The **snmp-server location** command is used to configure or delete the system location.

The **snmp-server device-id** command is used to configure the system serial number or restore the default value.

The **snmp-server packetsize** command is used to configure the maximum packet length of the agent or restore the default value.

The **snmp-server net-id** command is used to configure or delete the device NE information.

The **snmp-server udp-port** command is used to set the UDP port ID of the SNMP service or restore the default value.

Configuring the SNMP Host Address

By default, no SNMP host is configured.

The **snmp-server host** command is used to configure the NMS host address to which the agent actively sends messages or to delete the specified SNMP host address. In the messages sent to the host, the SNMP version, receiving port, authentication name, or user can be bound. This command is used with the **snmp-server enable traps** command to actively send trap messages to the NMS.

Setting Trap Message Parameters

By default, SNMP is not allowed to actively send a trap message to the NMS, the function of sending a Link Trap message on an interface is enabled, the function of sending a system reboot trap message is disabled, and a trap message does not carry any private field.

By default, the IP address of the interface where SNMP packets are sent is used as the source address.

By default, the length of a trap message queue is 10 and the interval for sending a trap message is 30s.

The **snmp-server enable traps** command is used to enable or disable the agent to actively send a trap message to the NMS.

The **snmp trap link-status** command is used to enable or disable the function of sending a Link Trap message on an interface.

The **snmp-server trap-source** command is used to specify the source address for sending messages or to restore the default value.

The **snmp-server queue-length** command is used to set the length of a trap message queue or to restore the default value.

The **snmp-server trap-timeout** command is used to set the interval for sending a trap message or to restore the default value.

The **snmp-server trap-format private** command is used to set or disable the function of carrying private fields in a trap message when the message is sent.

The **snmp-server system-shutdown** command is used to enable or disable the function of sending a system reboot trap message.

📌 Setting the SNMP Attack Protection and Detection Function

By default, the SNMP attack protection and detection function is disabled.

The **snmp-server authentication attempt *times* exceed { lock | lock-time *minutes* | unlock }** command is used to set and enable the attack protection and detection function.

1.3.2 SNMPv1 and SNMPv2C

SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

Working Principle

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. The authentication name of the NMS must be the same as an authentication name defined in devices.

SNMPv2C adds the Get-bulk operation mechanism and can return more detailed error message types to the management workstation. The Get-bulk operation is performed to obtain all information from a table or obtain lots of data at a time, so as to reduce the number of request responses. The enhanced error handling capabilities of SNMPv2C include extension of error codes to differentiate error types. In SNMPv1, however, only one error code is provided for errors. Now, errors can be differentiated based on error codes. Because management workstations supporting SNMPv1 and SNMPv2C may exist on the

network, the SNMP agent must be able to identify SNMPv1 and SNMPv2C packets and return packets of the corresponding versions.

▾ Security

One authentication name has the following attributes:

- Read-only: Provides the read permission of all MIB variables for authorized management workstations.
- Read-write: Provide the read/write permission of all MIB variables for authorized management workstations.

Related Configuration

▾ Setting Authentication Names and Access Permissions

The default access permission of all authentication names is read-only.

The **snmp-server community** command is used to configure or delete an authentication name and access permission.

This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.

1.3.3 SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2 into the SNMPv3 system.

Working Principle

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using the services provided by the SNMP engine.

SNMPv3v determines whether a user has the right to use MIB objects by using the User-based Security Model (USM). The security level of the NMS user must be the same as that of an SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain the SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the discover and report operation mechanisms. When the NMS does not know agent engine IDs, the NMS may first send a discover message to the agent and the agent returns a report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

▾ Security

- SNMPv3 determines the data security mechanism based on the security model and security level. At present, security models include: SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

SNMPv1 and SNMPv2C Security Models and Security Levels

Security Model	Security Level	Authentication	Encryption	Description
----------------	----------------	----------------	------------	-------------

SNMPv1	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.
SNMPv2c	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed through authentication name.

SNMPv3 Security Model and Security Level

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	User name.	N/A	Data validity is confirmed through user name.
SNMPv3	authNoPriv	MD5 or SHA	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5 or SHA	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and data encryption mechanism based on CBC-DES are provided.

Engine ID

An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, one SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must have a unique engine ID, that is, SmpEngineID.

An engine ID is an octet string that consists of 5 to 32 bytes. RFC3411 defines the format of an engine ID:

- The first four bytes indicate the private enterprise ID (allocated by IANA) of a vendor, which is expressed in hexadecimal.
- The fifth byte indicates remaining bytes:
- 0: Reserved.
- 1: The later four bytes indicate an IPv4 address.
- 2: The later 16 bytes indicate an IPv6 address.
- 3: The later six bytes indicate a MAC address.
- 4: Text consisting of 27 bytes, which is defined by the vendor.
- 5: Hexadecimal value consisting of 27 bytes, which is defined by the vendor.
- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

Related Configuration

Configuring an MIB View and a Group

By default, one view is configured and all MIB objects can be accessed.

By default, no user group is configured.

The **snmp-server view** command is used to configure or delete a view and the **snmp-server group** command is used to configure or delete a user group.

One or more instructions can be configured to specify different community names so that network devices can be managed by NMSs of different permissions.

▾ Configuring an SNMP User

By default, no user is configured.

The **snmp-server user** command is used to configure or delete a user.

The NMS can communicate with the agent by using only legal users.

An SNMPv3 user can specify the security level (whether authentication and encryption are required), authentication algorithm (MD5 or SHA), authentication password, encryption password (only DES is available currently), and encryption password.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic SNMP Functions	 (Mandatory) It is used to enable users to access the agent through the NMS.	
	enable service snmp-agent	Enables the agent function.
	snmp-server community	Sets an authentication name and access permission.
	snmp-server user	Configures an SNMP user.
	snmp-server view	Configures an SNMP view.
	snmp-server group	Configures an SNMP user group.
	snmp-server authentication	Configures the SNMP attack protection and detection function.
Enabling the Trap Function	 (Optional) It is used to enable the agent to actively send a trap message to the NMS.	
	snmp-server host	Configures the NMS host address.
	snmp-server enable traps	Enables the agent to actively send a trap message to the NMS.
	snmp trap link-status	Enables the function of sending a Link Trap message on an interface.
	snmp-server system-shutdown	Enables the function of sending a system reboot trap message.
	snmp-server trap-source	Specifies the source address for sending a trap message.
	snmp-server trap-format private	Enables a trap message to carry private fields when the message is sent.
Shielding the Agent Function	 (Optional) It is used to shield the agent function when the agent service is not required.	

Configuration	Description and Command	
	no snmp-server	Shields the agent function.
Setting SNMP Control Parameters	 (Optional) It is used to set or modify SNMP control parameters.	
	snmp-server contact	Sets the device contact mode.
	snmp-server location	Sets the device location.
	snmp-server logging	Sets the logging function.
	snmp-server device-id	Sets the serial number of the device.
	snmp-server net-id	Sets NE information about the device.
	snmp-server packetsize	Modifies the maximum packet length.
	snmp-server udp-port	Modifies the UDP port ID of the SNMP service.
	snmp-server queue-length	Modifies the length of a trap message queue.
	snmp-server trap-timeout	Modifies the interval for sending a trap message.

1.4.1 Configuring Basic SNMP Functions

Configuration Effect

Enable users to access the agent through the NMS.

Notes

- By default, no authentication name is set on network devices and SNMPv1 or SNMPv2C cannot be used to access the MIB of network devices. When an authentication name is set, if no access permission is specified, the default access permission is read-only.

Configuration Steps

▾ Configuring an SNMP View

- Optional
- An SNMP view needs to be configured when the View-based Access Control Model (VACM) is used.

▾ Configuring an SNMP User Group

- Optional
- An SNMP user group needs to be configured when the VACM is used.

▾ Configuring an Authentication Name and Access Permission

- Mandatory
- An authentication name must be set on the agent when SNMPv1 and SNMPv2C are used to manage network devices.

▾ Configuring an SNMP User

- Mandatory
- A user must be set when SNMPv3 is used to manage network devices.

↳ **Enabling the Agent Function**

- Optional
- By default, the agent function is enabled. When the agent function needs to be enabled again after it is disabled, this command must be used.

↳ **Enabling the SNMP Attack Protection and Detection Function**

- Optional
- By default, the SNMP attack protection and detection function is disabled. When malicious attacks need to be prevented, the configuration item must be used on the agent.

Verification

Run the **show snmp** command to check the SNMP function on devices.

Related Commands

↳ **Configuring an SNMP View**

Command	snmp-server view <i>view-name oid-tree</i> { include exclude }
Parameter	<i>view-name</i> : View name
Description	<i>oid-tree</i> : MIB objects associated with a view, which are displayed as an MIB subtree. include : Indicates that the MIB object subtree is included in the view. exclude : Indicates that the MIB object subtree is not included in the view.
Command Mode	Global configuration mode
Usage Guide	Specify a view name and use it for view-based management.

↳ **Configuring an SNMP User Group**

Command	snmp-server group <i>groupname</i> { v1 v2c v3 { auth noauth priv } } [read <i>readview</i>] [write <i>writeview</i>] [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter	v1 v2c v3 : Specifies the SNMP version.
Description	auth : Messages sent by users in the group need to be verified but data confidentiality is not required. This configuration is valid for SNMPv3 only. noauth : Messages sent by users in the group do not need to be verified and data confidentiality is not required. This configuration is valid for SNMPv3 only. priv : Messages sent by users in the group need to be verified and confidentiality of transmitted data is required. This configuration is valid for SNMPv3 only. <i>readview</i> : Associates one read-only view. <i>writeview</i> : Associates one read/write view.

	<p><i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname</i>: IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p>
Command Mode	Global configuration mode
Usage Guide	Associate certain users with a group and associate the group with a view. Users in a group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.

📌 Configuring an Authentication Name and Access Permission

Command	snmp-server community [0 7] <i>string</i> [view <i>view-name</i>] [[ro rw] [host <i>ipaddr</i>]] [ipv6 <i>ipv6-aclname</i>] [<i>aclnum</i> <i>aclname</i>]
Parameter Description	<p>0: Indicates that the input community string is a plaintext string.</p> <p>7: Indicates that the input community string is a ciphertext string.</p> <p><i>string</i>: Community string, which is equivalent to the communication password between the NMS and the SNMP agent.</p> <p><i>view-name</i>: Specifies a view name for view-based management.</p> <p>ro: Indicates that the NMS can only read variables of the MIB.</p> <p>rw: The NMS can read and write variables of the MIB.</p> <p><i>aclnum</i>: ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname</i>: ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname</i>: ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipaddr</i>: Associates NMS addresses and specifies NMS addresses for accessing the MIB.</p>
Command Mode	Global configuration mode
Usage Guide	<p>This command is the first important command for enabling the SNMP agent function. It specifies community attributes and NMS scope where access to the MIB is allowed.</p> <p>To disable the SNMP agent function, run the no snmp-server command.</p>

📌 Configuring an SNMP User

Command	snmp-server user <i>username</i> <i>groupname</i> { v1 v2c v3 [encrypted] [auth { md5 sha } <i>auth-password</i>] [priv des56 <i>priv-password</i>] } [access { ipv6 <i>ipv6-aclname</i> <i>aclnum</i> <i>aclname</i> }]
Parameter Description	<p><i>username</i>: User name.</p> <p><i>groupname</i>: Specifies the group name for a user.</p> <p>v1 v2c v3: Specifies the SNMP version. Only SNMPv3 supports later security parameters.</p>

	<p>encrypted: The specified password input mode is ciphertext input. Otherwise, plaintext is used for input. If ciphertext input is selected, enter a key consisting of continuous hexadecimal digits. An MD5 protocol authentication key consists of 16 bytes and an SHA authentication protocol key consists of 20 bytes. Two characters stand for one byte. Encrypted keys are valid for this engine only.</p> <p>auth: Specifies whether authentication is used.</p> <p>md5: Specifies the MD5 authentication protocol. sha specifies the SHA authentication protocol.</p> <p><i>auth-password:</i> Configures a password string (not more than 32 characters) used by the authentication protocol. The system converts the passwords into the corresponding authentication keys.</p> <p>priv: Specifies whether confidentiality is used. des56 specifies the use of the 56-bit DES encryption protocol.</p> <p><i>priv-password:</i> Configures a password string (not more than 32 characters) used for encryption. The system converts the password into the corresponding encryption key.</p> <p><i>aclnum:</i> ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>aclname:</i> ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified.</p> <p><i>ipv6-aclname:</i> IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.</p>
Command Mode	Global configuration mode
Usage Guide	Configure user information so that the NMS can communicate with the agent by using a valid user. For an SNMPv3 user, you can specify the security level, authentication algorithm (MD5 or SHA), authentication password, encryption algorithm (at present, only DES is available), and encryption password.

📄 **Enabling the Agent Function**

Command	enable service snmp-agent
Parameter Description	N/A
Configuration mode	Privileged mode.
Usage Guide	This command is used to enable the SNMP agent function of a device.

📄 **Enabling the SNMP Attack Protection and Detection Function**

Command	snmp-server authentication attempt <i>times</i> exceed { lock lock-time <i>minutes</i> unlock }
Parameter Description	<p><i>times:</i> Number of continuous failed attempts.</p> <p>lock: After continuous authentication fails, the source IP address is permanently forbidden to initiate authentication for access. The administrator needs to manually unlock the IP address.</p> <p>lock-time <i>minutes</i>: After continuous authentication fails, the source IP address is forbidden to initiate authentication for access in a period of time. Beyond the period, the source IP address can be authenticated for access again.</p> <p>unlock: After continuous authentication fails, the source IP address is allowed to access the MIB</p>

	continuously, which is equivalent to the fact that the SNMP attack protection and detection function is not configured.
Command Mode	Global configuration mode
Usage Guide	<p>Configure the SNMP attack protection and detection function so that the corresponding measure can be taken after continuous authentication fails.</p> <p>The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses.</p> <p>The source IP address that are forbidden to access the MIB in a period of time can be authenticated for access again after the period expires or after the administrator manually unlocks the IP addresses.</p>

↘ **Displaying the SNMP Status Information**

Command	show snmp [mib user view group host process-mib-time]
Parameter Description	<p>mib: Displays information about the SNMP MIB supported in the system.</p> <p>user: Displays information about an SNMP user.</p> <p>view: Displays information about an SNMP view.</p> <p>group: Displays information about an SNMP user group.</p> <p>host: Displays information about user configuration.</p> <p>process-mib-time: Displays the MIB node with the longest processing time.</p>
Configuration mode	Privileged mode.
Usage Guide	N/A

↘ **Configuring SNMPv3 Configuration**

<p>Scenario Figure 1-5</p>	 <p>The diagram illustrates a network connection between an Agent and an NMS. The Agent is represented by a blue square icon with a crosshair, and the NMS is represented by a blue server rack icon. They are connected by a horizontal line labeled 'Gi0/1'. Below the Agent icon is the IP address 'IP: 192.168.3.1/24', and below the NMS icon is the IP address 'IP: 192.168.3.2/24'.</p> <ul style="list-style-type: none"> ● The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses user1 as the user name, MD5 as the authentication mode, 123 as the authentication password, DES56 as the encryption algorithm, and 321 as the encryption password. ● Network devices can control the operation permission of users to access MIB objects. For example, the user named user1 can read MIB objects under the system node (1.3.6.1.2.1.1) and can only write MIB objects under the SysContact node (1.3.6.1.2.1.1.4.0). ● Network devices can actively send authentication and encryption messages to the NMS.
Configuration Steps	<ul style="list-style-type: none"> ● Configure a MIB view and a MIB group. Create a MIB view “view1”, which includes the associated MIB object (1.3.6.1.2.1.1); then create a MIB view “view2”, which includes the associated MIB object (1.3.6.1.2.1.1.4.0). Create a group “g1”, select the version “v3”, set the security level to the

```
snmp-server group gl v3 priv read view1 write view2

1.4.2 Enabling the Trap Function

Configuration Effect

Enable the agent to actively send a trap message to the NMS.

Notes

N/A

Configuration Steps

➤ Configuring the SNMP Host Address

- Optional
- Configure the host address of the NMS when the agent is required to actively send messages.

➤ Enabling the Agent to Actively Send a Trap Message to the NMS

- Optional
- Configure this item on the agent when the agent is required to actively send a trap message to the NMS.

➤ **Enabling the Function of Sending a Link Trap Message on an Interface**

- Optional
- Configure this item on the agent when a link trap message needs to be sent on an interface.

➤ **Enabling the Function of Sending a System Reboot Trap Message**

- Optional
- Configure this item on the agent when the NXOS system is required to send a trap message to the NMS to notify system reboot before reloading or reboot of the device.

➤ **Specifying the Source Address for Sending a Trap Message**

- Optional
- Configure this item on the agent when it is required to permanently use a local IP address as the source SNMP address to facilitate management.

➤ **Enabling a Trap Message to Carry Private Fields when the Message Is Sent**

- Optional
- Configure this item on the agent when private fields need to be carried in a trap message.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

➤ **Setting the NMS Host Address**

Command	snmp-server host [oob] { <i>host-addr</i> ipv6 <i>ipv6-addr</i> } [vrf <i>vrfname</i>] [traps informs] [version { 1 2c 3 } { auth noauth priv }] <i>community-string</i> [udp-port <i>port-num</i>] [<i>notification-type</i>]
Parameter Description	<p>oob: Configures Out-Of-Band (OOB) communication for the alarm server (that is, information is sent to the alarm server through the MGMT interface).</p> <p><i>host-addr:</i> Address of the SNMP host.</p> <p><i>ipv6-addr:</i> (IPv6) address of the SNMP host.</p> <p><i>Vrfname:</i> Configures a VRF forwarding table name.</p> <p>traps informs: Configures the host to send a trap message or an inform message.</p> <p>version: SNMP version, which can be set to V1, V2C, or V3.</p> <p>auth noauth priv: Sets the security level of V3 users.</p> <p><i>community-string:</i> Community string or user name (V3).</p> <p><i>port-num:</i> Configures the port ID of the SNMP host.</p> <p><i>notification-type:</i> Type of trap messages that are actively sent, for example, snmp.</p> <hr/> <p> If no trap type is specified, all trap messages are sent.</p>

Command Mode	Global configuration mode
Usage Guide	<p>This command is used with the snmp-server enable traps command to actively send trap messages to the NMS.</p> <p>You can configure different SNMP hosts to receive trap messages. A host can support different traps, ports, and VRF forwarding tables. If the same host is configured (the port and VRF configuration are the same), the last configuration is combined with the previous configurations, that is, to send different trap messages to the same host, configure one type of trap messages each time. These configurations are finally combined.</p>

↳ Enabling the Agent to Actively Send a Trap Message to the NMS

Command	snmp-server enable traps [<i>notification-type</i>]
Parameter Description	<p><i>notification-type</i>: Enables trap notification for the corresponding events, including the following types:</p> <p>snmp: Enables trap notification for SNMP events.</p> <p>bgp: Enables trap notification for BGP events.</p> <p>bridge: Enables trap notification for bridge events.</p> <p>isis: Enables trap notification for ISIS events.</p> <p>mac-notification: Enables trap notification for MAC events.</p> <p>ospf: Enables trap notification for OSPF events.</p> <p>urpf: Enables trap notification for URPF events.</p> <p>vrrp: Enables trap notification for VRRP events.</p> <p>web-auth: Enables trap notification for Web authentication events.</p>
Command Mode	Global configuration mode
Usage Guide	This command must be used with the snmp-server host command to so that trap messages can be actively sent.

↳ Enabling the Function of Sending a Link Trap Message on an Interface

Command	snmp trap link-status
Parameter Description	-
Configuration mode	Interface configuration mode
Usage Guide	For interfaces (Ethernet interface, AP interface, and SVI interface), when this function is enabled, the SNMP sends a Link Trap message if the link status on the interfaces changes. Otherwise, the SNMP does not send the message.

↳ Enabling the Function of Sending a System Reboot Trap Message

Command	snmp-server system-shutdown
Parameter Description	-

Configuration mode	Global configuration mode
Usage Guide	When the function of notification upon SNMP system reboot is enabled, a trap message is sent to the NMS to notify system reboot before reloading or reboot of the device.

➤ **Specifying the Source Address for Sending a Trap Message**

Command	snmp-server trap-source <i>interface</i>
Parameter Description	<i>interface</i> : Used as the interface for the SNMP source address.
Configuration mode	Global configuration mode
Usage Guide	By default, the IP address of the interface where SNMP packets are sent is used as the source address. To facilitate management and identification, this command can be run to permanently use one local IP address as the source SNMP address.

➤ **Enabling a Trap message to Carry Private Fields when the Message Is Sent**

Command	snmp-server trap-format private
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to enable a trap message to carry private fields when the message is sent. At present, supported private fields include the alarm generation time. For the specific data types and data ranges of the fields, see Nodexon-TRAP-FORMAT-MIB.mib.

Configuration Example

➤ **Enabling the Trap Function**

Scenario Figure 1-6	 <p>The diagram illustrates a network setup where an Agent (represented by a blue cube icon) is connected to an NMS (represented by a blue server icon) via the Gi0/1 interface. The Agent's IP address is 192.168.3.1/24, and the NMS's IP address is 192.168.3.2/24.</p> <ul style="list-style-type: none"> The NMS manages network devices (agents) based on the community authentication mode, and network devices can actively send messages to the NMS.
Configuration Steps	<ol style="list-style-type: none"> Perform configuration to enable the agent to actively send messages to the NMS. Set the SNMP host address to 192.168.3.2, the message format to Version2c, and the authentication name to user1. Enable the agent to actively send trap messages. Set the IP address of the agent. Set the address of the Gi0/1 interface to 192.168.3.1/24.

Common Errors

N/A

1.4.3 Shielding the Agent Function

Configuration Effect

Shield the agent function when the agent service is not required.

Notes

- Run the **no snmp-server** command to shield the SNMP agent function when the agent service is not required.
- Different from the shielding command, after the **no enable service snmp-agent** command is run, all SNMP services are directly disabled (that is, the SNMP agent function is disabled, no packet is received, and no response packet or trap packet is sent), but configuration information of the agent is not shielded.

Configuration Steps

▾ Shielding the SNMP Agent Function for the Device

- Optional
- To shield the configuration of all SNMP agent services, use this configuration.

▾ Disabling the SNMP Agent Function for the Device

- Optional
- To directly disable all services, use this configuration.

Verification

Run the **show services** command to check whether SNMP services are enabled or disabled.

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

Shielding the SNMP Agent Function for the Device

Command	no snmp-server
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	<p>By default, the SNMP agent function is disabled. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are set, the SNMP agent service is automatically enabled. The enable service snmp-agent command must also be run at the same time so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the enable service snmp-agent command is not run, the SNMP agent service does not take effect. Run the no snmp-server command to disable SNMP agent services of all versions supported by the device.</p> <p>After this command is run, all SNMP agent service configurations are shielded (that is, after the show running-config command is run, no configuration is displayed. Configurations are restored after the SNMP agent service is enabled again). After the enable service snmp-agent command is run, the SNMP agent configurations are not shielded.</p>

Disabling the SNMP Agent Function for the Device

Command	no enable service snmp-agent
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to disable the SNMP service, but it will not shield SNMP agent parameters.

Configuration Example

Enabling the SNMP Service

<p>Scenario Figure 1-7</p>	 <p>After the SNMP service is enabled and the SNMP agent server is set, the NMS can access devices based on SNMP.</p>
<p>Configuration Steps</p>	<ol style="list-style-type: none"> 1. Enable the SNMP service. 2. Set parameters for the SNMP agent server to make the SNMP service take effect.
<p>A gent</p>	<pre>Nodexon(config)#enable service snmp-agent</pre>
<p>Verification</p>	<ol style="list-style-type: none"> 1. Run the show services command to check whether the SNMP service is enabled or disabled.

Common Errors

N/A

1.4.4 Setting SNMP Control Parameters

Configuration Effect

Set basic parameters of the SNMP agent, including the device contact mode, device location, serial number, and parameters for sending a trap message. By accessing the parameters, the NMS can obtain the contact person of the device and physical location of the device.

Notes

N/A

Configuration Steps

▾ **Setting the System Contact Mode**

- Optional

- When the contact mode of the system needs to be modified, configure this item on the agent.
- ↳ **Setting the System Location**
- Optional
- When the system location needs to be modified, configure this item on the agent.
- ↳ **Setting the System Serial Number**
- Optional
- When the system serial number needs to be modified, configure this item on the agent.
- ↳ **Setting NE Information about the Device**
- Optional
- When the NE code needs to be modified, configure this item on the agent.
- ↳ **Setting the Maximum Packet Length of the SNMP Agent**
- Optional
- When the maximum packet length of the SNMP agent needs to be modified, configure this item on the agent.
- ↳ **Setting the UDP Port ID of the SNMP Service**
- Optional
- When the UDP port ID of the SNMP service needs to be modified, configure this item on the agent.
- ↳ **Setting the Queue Length of Trap Messages**
- Optional
- When the size of the message queue needs to be adjusted to control the message sending speed, configure this item on the agent.
- ↳ **Setting the Interval for Sending a Trap Message**
- Optional
- When the interval for sending a trap message needs to be modified, configure this item on the agent.
- ↳ **Configuring SNMP Flow Control**
- Optional
- If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display configuration information of the device.

Related Commands

Setting the System Contact Mode

Command	snmp-server contact <i>text</i>
Parameter Description	<i>text</i> : String that describes the system contact mode.
Command Mode	Global configuration mode
Usage Guide	N/A

Setting the System Location

Command	snmp-server location <i>text</i>
Parameter Description	<i>text</i> : String that describes system information.
Configuration mode	Global configuration mode
Usage Guide	N/A

Setting the System Serial Number

Command	snmp-server device-id <i>text</i>
Parameter Description	<i>text</i> : Text of the system serial number, which may be digits or characters.
Configuration mode	Global configuration mode
Usage Guide	In general, the device serial number is used as the SNMP serial number to facilitate identification of the device.

Setting NE Information about the Device

Command	snmp-server net-id <i>text</i>
Parameter Description	<i>text</i> : Text that is used to set the device NE code. The text is a string that consists of 1 to 255 characters that are case-sensitive and may include spaces.
Configuration mode	Global mode.
Usage Guide	Set the NE code of the device.

Setting the Maximum Packet Length of the SNMP Agent

Command	snmp-server packet-size <i>byte-count</i>
Parameter Description	<i>byte-count</i> : Packet size, ranging from 484 bytes to 17,876 bytes.

Configuration mode	Global mode.
Usage Guide	N/A

▾ Setting the UDP Port ID of the SNMP Service

Command	snmp-server udp-port <i>port-num</i>
Parameter Description	<i>port-num</i> : Specifies the UDP port ID of the SNMP service, that is, the ID of the protocol port that receives SNMP packets.
Configuration mode	Global mode.
Usage Guide	Specify the protocol port ID for receiving SNMP packets.

▾ Setting the Length of a Trap Message Queue

Command	snmp-server queue-length <i>length</i>
Parameter Description	<i>length</i> : Queue length, ranging from 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the size of the message queue to control the message sending speed.

▾ Setting the Interval for Sending a Trap Message

Command	snmp-server trap-timeout <i>seconds</i>
Parameter Description	<i>seconds</i> : Interval (unit: second). The value range is 1 to 1,000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the interval for sending a message to control the message sending speed.

▾ Configuring SNMP Flow Control

Command	snmp-server flow-control pps [<i>count</i>]
Parameter Description	<i>count</i> : Number of SNMP request packets processed per second. The value range is 50 to 65,535.
Command Mode	Global configuration mode
Usage Guide	If a large number of SNMP request packets result in high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Configuration Example

▾ Setting SNMP Control Parameters

2 Configuring RMON

2.1 Overview

The Remote Network Monitoring (RMON) aims at resolving problems of managing local area networks (LANs) and remote sites by using one central point. In RMON, network monitoring data consists of a group of statistics and performance indicators, which can be used for monitoring the network utilization, so as to facilitate network planning, performance optimization, and network error diagnosis.

RMON is mainly used by a managing device to remotely monitor and manage managed devices.

Protocols and Standards

STD 0059 / RFC 2819: Remote Network Monitoring Management Information Base

RFC4502: Remote Network Monitoring Management Information Base Version 2

RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)

RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules

RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms

RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions

RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services

RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks

RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros

RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

2.2 Applications

Application	Description
Collecting Statistics on Information of a Monitored Interface	Applies four functions of RMON to an interface to monitor the network communication of the interface.

2.2.1 Collecting Statistics on Information of a Monitored Interface

Scenario

The RMON Ethernet statistics function is used to monitor accumulated information of an interface, the history statistics function is used to monitor the packet count of an interface within each monitoring interval, and the alarm function is used to immediately acquire packet count exceptions of an interface. The following figure shows the networking topology.

Figure 2-1

Deployment

Interface is monitored to accumulatively collect statistics on the packet count of the interface and collect statistics on the packet count and bandwidth utilization of the interface within the monitoring interval. If a packet count exception occurs on the interface, an alarm is reported to the network management system (NMS). The configuration key points are as follows:

- Configure the RMON Ethernet statistics function on interface.
- Configure the RMON history statistics function on interface.
- Configure the RMON alarm table and define RMON event processing actions in configuration mode. Monitored objects of alarms are the object identifier (OID) values of specific fields in the RMON Ethernet statistical table configured for interface.

2.3 Features

Basic Concepts

RMON defines multiple RMON groups. Nodexon products support the statistics group, history group, alarm group, and event group, which are described as follows:

Statistics Group

The statistics group is used to monitor and collect statistics on Ethernet interface traffic information, which is accumulated from the entry creation time to the current time. The statistical items include discarded data packets, broadcast data packets, cyclic redundancy check (CRC) errors, large and small blocks, and collisions. Statistical results are stored in the Ethernet statistical table.

History Group

The history group is used to periodically collect network traffic information. It records accumulated values of network traffic information and the bandwidth utilization within each interval, and saves them in the history control table. It includes two small groups:

- The HistoryControl group is used to set the sampling interval, sampling data source, and other control information.

- The EthernetHistory group provides administrators with historical data, including statistics on network segment traffic, error packets, broadcast packets, utilization, and number of collisions.

Alarm Group

The alarm group is used to monitor a specified Management Information Base (MIB) object. When the value of a MIB object exceeds the preset upper limit or is lower than the preset lower limit, an alarm is triggered and the alarm is processed as an event.

Event Group

The event group is used to define the event processing mode. When a monitored MIB object meets alarm conditions, an event is triggered. An event can be processed in any of the following modes:

- none: No action is taken.
- log: Event-relevant information is recorded in the log record table so that administrators can view it at any time.
- snmp-trap: A trap message is transmitted to the NMS to notify the NMS of the event occurrence.
- log-and-trap: Event-relevant information is recorded in the log record table and a trap message is transmitted to the NMS.

Working Principle

RMON supports multiple monitors and two data collection methods. Method 1: A dedicated RMON probe is used to collect data and the NMS can directly acquire all information about the RMON MIB from the RMON probe. Method 2: RMON agents are built into network devices (such as switches and routers) so that the devices have the RMON probe function. The NMS uses basic commands of the Simple Network Management Protocol (SNMP) to exchange data with the RMON agents and collect network management information. This method, however, is limited by device resources and information of only four groups rather than all data of the RMON MIB is acquired.

The following figure shows an example of communication between the NMS and RMON agents. The NMS, through the RMON agents running on devices, can acquire information about overall traffic, error statistics, and performance statistics of the network segment where a managed network device interface is, thereby implementing remote management of network devices.

Figure 2-2

Overview

Feature	Description
RMON Ethernet Statistics	Collects statistics on the packet count, byte count, and other data of a monitored Ethernet interface accumulatively.
RMON History Statistics	Records the counts of packets, bytes, and other data communicated by an Ethernet interface within the configured interval and calculates the bandwidth utilization within the interval.
RMON Alarm	Samples values of monitored variables at intervals. The alarm table is used in combination with the event table. When the upper or lower limit is reached, a relevant event table is triggered to perform event processing or no processing is performed.

2.3.1 RMON Ethernet Statistics

Working Principle

The RMON Ethernet statistics function accumulatively collects statistics on network traffic information of an Ethernet interface from the entry creation time to the current time.

Related Configuration

▾ [Configuring RMON Statistical Entries](#)

- The RMON Ethernet statistics function is disabled by default.
- Run the **rmon collection stats** command to create Ethernet statistical entries on a specified Ethernet interface.
- After statistical entries are successfully created on a specified interface, the statistics group collects statistics on the traffic information of the current interface. The statistical items are variables defined in the RMON Ethernet statistical table, and recorded information is the accumulated values of variables from the creation time of the RMON statistical table to the current time.

2.3.2 RMON History Statistics

Working Principle

The RMON history statistics function records accumulated statistics on traffic information of an Ethernet interface within each interval.

Related Configuration

▾ [Configuring RMON Historical Control Entries](#)

- The RMON history statistics function is disabled by default.
- Run the **rmon collection history** command to create historical control entries on an Ethernet interface.
- The RMON history group collects statistics on variables defined in the RMON history table and records accumulated values of variables within each interval.

2.3.3 RMON Alarm

Working Principle

The RMON alarm function periodically monitors value changes of alarm variables. If the value of an alarm variable reaches the specified upper threshold or lower threshold, a corresponding event is triggered for processing, for example, a trap message is transmitted or one logTable entry record is generated. If a lower threshold or upper threshold is reached multiple times consecutively, only one corresponding event is triggered and another event is triggered till a reverse threshold is reached.

Related Configuration

Configuring the Event Table

- The RMON event group function is disabled by default.
- Run the **rmon event** command to configure the event table.

Configuring Alarm Entries

- The RMON alarm group function is disabled by default.
- Run the **rmon event** command to configure the event table and run the **rmon alarm** command to configure the RMON alarm table.
- The RMON alarm function is implemented by the alarm table and event table jointly. If a trap message needs to be transmitted to a managing device in the case of an alarm event, the SNMP agent must be correctly configured first. For the configuration of the SNMP agent, see the *Configuring SNMP*.
- If a configured alarm object is a field node in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function need to be configured on a monitored Ethernet interface first.

2.4 Configuration

Configuration	Description and Command		
Configuring RMON Ethernet Statistics	 (Mandatory) It is used to accumulatively collect statistics on traffic information of an Ethernet interface.		
	<table border="1"> <tr> <td>rmon collection stats</td> <td>Configures Ethernet statistical entries.</td> </tr> </table>	rmon collection stats	Configures Ethernet statistical entries.
rmon collection stats	Configures Ethernet statistical entries.		
Configuring RMON History Statistics	 (Mandatory) It is used to collect, at intervals, statistics on traffic information of an Ethernet interface and the bandwidth utilization within the interval.		
	<table border="1"> <tr> <td>rmon collection history</td> <td>Configures historical control entries.</td> </tr> </table>	rmon collection history	Configures historical control entries.
rmon collection history	Configures historical control entries.		
Configuring RMON Alarm	 (Mandatory) It is used to monitor whether data changes of a variable is within the valid range.		
	<table border="1"> <tr> <td>rmon event</td> <td>Configures event entries.</td> </tr> </table>	rmon event	Configures event entries.
	rmon event	Configures event entries.	
<table border="1"> <tr> <td>rmon alarm</td> <td>Configures alarm entries.</td> </tr> </table>	rmon alarm	Configures alarm entries.	
rmon alarm	Configures alarm entries.		

2.4.1 Configuring RMON Ethernet Statistics

Configuration Effect

Acquire accumulated statistics on traffic information of a monitored Ethernet interface from the entry creation time to the current time.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

Configuring RMON Statistical Entries

- Mandatory.
- If statistics and monitoring are required for a specified interface, Ethernet statistical entries must be configured on this interface.

Verification

Run the **show rmon stats** command to display Ethernet statistics.

Related Commands

Configuring RMON Statistical Entries

Command	rmon collection stats <i>index</i> [owner <i>ownername</i>]
Parameter	<i>index</i> : Indicates the index number of a statistical entry, with the value ranging from 1 to 65,535.
Description	owner <i>ownername</i> : Indicates the entry creator, that is, <i>ownername</i> , which is a case-sensitive string of 1-63 characters.
Command Mode	Interface configuration mode
Usage Guide	The values of statistical entry parameters cannot be changed.

Configuration Example

Configuring RMON Ethernet Statistics

<p>Scenario</p> <p>Figure 2-3</p>	<pre> graph LR Server[Server] --- Gi0/1[Gi0/1] --- Agent[Agent] Agent --- Network((Network)) Agent --- Console[Console] --- Terminal[Terminal] </pre>
	<p>As shown in the preceding figure, the RMON agent is connected to the server, and the NMS requires the</p>

	<p>RMON statistics group to conduct performance statistics on received packets of interface Gi0/1. Administrators can view the statistics at any time to understand data about received packets of an interface and take measures in a timely manner to handle network exceptions.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure a statistical table instance on interface GigabitEthernet 0/1 to collect statistics on the traffic of this interface.
<p>Agent</p>	<pre>Nodexon# configure terminal Nodexon (config)# interface gigabitEthernet 0/1 Nodexon (config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin</pre>
<p>Verification</p>	<p>Run the show rmon stats command to display Ethernet statistics.</p>
<p>Agent</p>	<pre>Nodexon# show rmon stats ether statistic table: index = 1 interface = GigabitEthernet 0/1 owner = admin status = 1 dropEvents = 0 octets = 25696 pkts = 293 broadcastPkts = 3 multiPkts = 0 crcAlignErrors = 0 underSizePkts = 0 overSizePkts = 0 fragments = 0 jabbers = 0 collisions = 0 packets640ctets = 3815 packets65To1270ctets = 1695 packets128To2550ctets = 365 packets256To5110ctets = 2542 packets512To10230ctets = 152</pre>

```
packets1024To15180ctets = 685
```

Common Errors

Statistical table entries are re-configured or configured statistical table entries are modified.

2.4.2 Configuring RMON History Statistics

Configuration Effect

Acquire accumulated statistics on the traffic of a monitored Ethernet interface and the bandwidth utilization within each interval.

Notes

This function cannot be configured in batch interface configuration mode.

Configuration Steps

- Mandatory.
- If network statistics on a specified interface need to be collected, RMON historical control entries must be configured on the interface.

Verification

Run the **show rmon history** command to display history group statistics.

Related Commands

↘ Configuring RMON Historical Control Entries

Command	rmon collection history <i>index</i> [owner <i>ownername</i>] [buckets <i>bucket-number</i>] [interval <i>seconds</i>]
Parameter Description	<p><i>index</i>: Indicates the index number of a history statistical entry, with the value ranging from 1 to 65,535.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p> <p>buckets <i>bucket-number</i>: Sets the capacity of the history table in which a history statistical entry exists, that is, sets the maximum number of records (<i>bucket-number</i>) that can be accommodated in the history table. The value of <i>bucket-number</i> ranges from 1 to 65,535 and the default value is 10.</p> <p>interval <i>seconds</i>: Sets the statistical interval, with the unit of seconds. The value ranges from 1 second to 3,600 seconds and the default value is 1,800 seconds.</p>
Command Mode	Interface configuration mode
Usage Guide	The values of history statistical entry parameters cannot be changed.

Configuration Example

↘ Configuring RMON History Statistics

<p>Scenario Figure 2-4</p>	 <p>The diagram illustrates the RMON agent configuration scenario. An Agent device is connected to a Server through its Gi0/1 interface. The Agent is also connected to a Network cloud. Additionally, the Agent has a Console connection to a Terminal.</p>
	<p>As shown in the preceding figure, the RMON agent is connected to the server, and the NMS needs to collect statistics on received packets of interface Gi0/1 through the RMON history group at an interval of 60 seconds, in an effort to monitor the network and understand emergency data.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> Configure the history control table on interface GigabitEthernet 0/1 to periodically collect statistics on the traffic of this interface.
<p>Agent</p>	<pre>Nodexon# configure terminal Nodexon(config)# interface gigabitEthernet 0/1 Nodexon(config-if-GigabitEthernet 0/1)# rmon collection history 1 buckets 5 interval 300 owner admin</pre>

Common Errors

History control table entries are re-configured or configured history control table entries are modified.

2.4.3 Configuring RMON Alarm

Configuration Effect

Periodically monitor whether value changes of alarm variables are within the specified valid range.

Notes

If a trap message needs to be transmitted to a managing device when an alarm event is triggered, the SNMP agent must be correctly configured. For the configuration of the SNMP agent, see the *Configuring SNMP*.

If an alarm variable is a MIB variable defined in the RMON statistics group or history group, the RMON Ethernet statistics function or RMON history statistics function must be configured on the monitored Ethernet interface. Otherwise, an alarm table fails to be created.

Configuration Steps

↘ **Configuring Event Entries**

- Mandatory.
- Complete the configuration in global configuration mode.

↘ **Configuring Alarm Entries**

- Mandatory.
- Complete the configuration in global configuration mode.

Verification

- Run the **show rmon event** command to display the event table.
- Run the **show rmon alarm** command to display the alarm table.

Related Commands

▾ Configuring the Event Table

Command	rmon event <i>number</i> [log] [trap <i>community</i>] [description <i>description-string</i>] [owner <i>ownername</i>]
Parameter	<i>number</i> : Indicates the index number of an event table, with the value ranging from 1 to 65,535.
Description	<p>log: Indicates a log event. The system logs a triggered event.</p> <p>trap <i>community</i>: Indicates a trap event. When an event is triggered, the system transmits a trap message with the community name of <i>community</i>.</p> <p>description <i>description-string</i>: Sets the description information about an event, that is, <i>description-string</i>. The value is a string of 1-127 characters.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>
Command Mode	Global configuration mode
Usage Guide	The values of configured event entry parameters can be changed, including the event type, trap community name, event description, and event creator.

▾ Configuring the RMON Alarm Group

Command	rmon alarm <i>number</i> <i>variable</i> <i>interval</i> { absolute delta } rising-threshold <i>value</i> [<i>event-number</i>] falling-threshold <i>value</i> [<i>event-number</i>] [owner <i>ownername</i>]
Parameter	<i>number</i> : Indicates the index number of an alarm entry, with the value ranging from 1 to 65,535.
Description	<p><i>variable</i>: Indicates an alarm variable, which is a string of 1-255 characters and is represented in dotted format using the node OID (format: entry.integer.instance; example: 1.3.6.1.2.1.2.1.10.1).</p> <p><i>interval</i>: Indicates the sampling interval, with the unit of seconds and the value ranging from 1 to 2,147,483,647.</p> <p>absolute: Indicates that the sampling type is absolute value sampling, that is, variable values are directly extracted when the sampling time is up.</p> <p>delta: Indicates that the sampling type is changing value sampling, that is, changes in the variable values within the sampling interval are extracted when the sampling time is up.</p> <p>rising-threshold <i>value</i>: Sets the upper limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p><i>event-number</i>: Indicates that an event with the event number of <i>event-number</i> is triggered when the upper limit or lower limit is reached.</p> <p>falling-threshold <i>value</i>: Sets the lower limit of the sampling quantity (<i>value</i>), with the value ranging from -2,147,483,648 to +2,147,483,647.</p> <p>owner <i>ownername</i>: Indicates the entry creator, that is, <i>ownername</i>, which is a case-sensitive string of 1-63 characters.</p>

Command Mode	Global configuration mode
Usage Guide	Values of configured alarm entry parameters can be changed, including alarm variables, sampling type, entry creator, sampling interval, upper/lower limit of the sampling quantity, and relevant trigger events.

Configuration Example

Configuring RMON Alarm

<p>Scenario Figure 2-5</p>	
	<p>Assume that SNMPv1 runs on the NMS, the community name used for accessing the settings is public, with the attribute of read-write, and the IP address used by the NMS to receive trap messages is 3.3.3.3.</p> <p>Assume that the OID value of unknown protocol packets received by monitored interface GigabitEthernet0/3 is 1.3.6.1.2.1.2.2.1.15.3, the sampling mode is relative sampling, and the sampling interval is 60 seconds. When the relative sampling value is larger than 100 or lower than 10, event 1 and event 2 are triggered respectively. In event 1, a trap message is transmitted and the event is logged. In event 2, the event is only logged.</p> <p>The configuration of the RMON agent is completed on the terminal. The RMON agent is connected to the NMS and is connected to the server through interface Gi0/1. The RMON agent needs to monitor the count of unknown protocol packets received by interface Gi0/1. The sampling interval is 60 seconds. When the absolute sampling value is smaller than 10, the event is only logged. When the absolute sampling value is larger than 100, the event is logged and a trap message is transmitted to the NMS.</p>
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● Configure the host address for receiving trap messages. ● Configure an event group to process alarm trigger. ● Configure the alarm function.
<p>Agent</p>	<pre>Nodexon# configure terminal Enter configuration commands, one per line. End with CNTL/Z. stauts: 1
    
```

Common Errors

- The entered OID of a monitored object is incorrect, the variable corresponding to the OID does not exist, or the type is not an integer or unsigned integer.
- The upper threshold is smaller than or equal to the lower threshold.

2.5 Monitoring

Displaying

Description	Command
Displays all RMON configuration information.	show rmon
Displays the Ethernet statistical table.	show rmon stats
Displays the history control table.	show rmon history
Displays the alarm table.	show rmon alarm
Displays the event table.	show rmon event

3 Configuring NTP

3.1 Overview

The Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than one millisecond in a LAN and smaller than decades of milliseconds in a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment.

Currently, Nodexon devices can be used both as NTP clients and NTP servers. In other words, a Nodexon device can synchronize time with a time server, and be used as a time server to provide time synchronization for other devices. When a Nodexon device is used as a server, it supports only the unicast server mode.

Protocols and Standards

- RFC 1305 : Network Time Protocol (Version 3)

3.2 Applications

Application	Description
Synchronizing Time Based on an External Reference Clock Source	A device is used as a client that synchronizes time with an external clock source. After successful synchronization, it is used as a server to provide time synchronization for other devices.
Synchronizing Time Based on a Local Reference Clock Source	A device uses a local clock as a reliable NTP reference clock source and is also used as a server to provide time synchronization for other devices.

3.2.1 Synchronizing Time Based on an External Reference Clock Source

Scenario

As shown in Figure 3-1:

- DEVICE-A is used as a reliable reference clock source to provide time synchronization for external devices.
- DEVICE-B specifies DEVICE-A as the NTP server and synchronizes time with DEVICE-A.
- After successful synchronization, DEVICE-B provides time synchronization for DEVICE-C.

Figure 3-1

Deployment

Configure DEVICE-B to the NTP external reference clock mode.

3.2.2 Synchronizing Time Based on a Local Reference Clock Source

Scenario

As shown in Figure 3-2, DEVICE-B uses a local clock as the NTP reference clock source and provides time synchronization for DEVICE-C.

Figure 3-2

Deployment

Configure DEVICE-B to the NTP local reference clock mode.

3.3 Features

Basic Concepts

📄 NTP Packet

As defined in RFC1305, NTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 3-3 shows the format of an NTP time synchronization packet.

Figure 3-3 Format of an NTP Time Synchronization Packet

0	7	15	23	31	
LI	VN	Mode	Stratum	Poll Interval	Precision
Root Delay (32-bit)					
Root Dispersion (32-bit)					
Reference Clock Identifier (32-bit)					
Reference Timestamp (64-bit)					
Originate Timestamp (64-bit)					
Receive Timestamp (64-bit)					
Transmit Timestamp (64-bit)					
Authenticator (optional 96-bit)					

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

- **i** 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.

- Version Number(VN): indicates a 3-bit NTP version number. The current version number is 3.
- Mode: indicates a 3-bit NTP working mode.

- **i** 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.

- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master reference clock source; other values: indicate slave reference clock sources.
- Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
- Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.
- Root Delay: indicates the round-trip time to the master reference clock source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

↘ NTP Server

A device uses a local clock as the reference clock source to provide time synchronization for other devices in the network.

↘ NTP Client

A device is used as an NTP client that synchronizes time with an NTP server in the network.

↘ Stratum

In NTP, "stratum" is used to describe the hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratums have higher clock precisions.

↘ Hardware Clock

A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

Overview

Feature	Description
NTP Time Synchronization	Network devices synchronize time with their servers or reliable clock sources to implement high-precision time correction.
NTP Security Authentication	The NTP packet encryption authentication is used to prevent unreliable clock sources from time synchronization interference on a device.
NTP Access Control	An Access Control List (ACL) is used to filter sources of received NTP packets.

3.3.1 NTP Time Synchronization

Working Principle

NTP time synchronization is implemented by interaction of NTP packets between a client and a server:

- The client sends a time synchronization packet to all servers every 64 seconds. After receiving response packets from the servers, the client filters and selects the response packets from all servers, and synchronizes time with an optimum server.
- After receiving the time synchronization request packet, a server uses the local clock as the reference source, and fills the local time information into the response packet to be sent to the client based on the protocol requirement.

Figure 3-4 shows the format of an NTP time synchronization packet.

Figure 3-4 Working Principle of NTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an NTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.

3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

▾ NTP Working Mode

- External clock reference mode

In this mode, a device is used as both a server and a client. If receiving time synchronization requests from other clients, the device must synchronize time with the specified server first and provide time synchronization for the clients after successful synchronization.

- Local clock reference mode

In this mode, a device uses the default local clock as the reliable clock source and provides time synchronization directly for other clients.

Related Configuration

▾ Configuring an NTP Server

- The NTP function is disabled by default.
- Run the **ntp server** command to specify an NTP server (external clock reference source), which can enable NTP.
- After the configuration, the device works in the external clock reference mode.

▾ Real-time Synchronization

- A device performs time synchronization every 64 seconds by default.

▾ Updating a Hardware Clock

- By default, a device does not update synchronized time to the hardware clock.
- Run the **ntp update-calendar** command to enable a device to automatically update the hardware clock after successfully synchronizing time each time.

▾ Configuring the NTP Master Clock

- By default, a device works in the external clock reference mode.
- Run the **ntp master** command to configure a device to the local clock reference mode.

3.3.2 NTP Security Authentication

To prevent malicious damage on an NTP server, NTP uses the authentication mechanism to check whether the time synchronization information is really from the announced server and check the information return path to provide an anti-interference protection mechanism.

Working Principle

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates the hash values of the packets by using the MD5 algorithm based on the specified key and NTP packet content, and fills the hash values into the packet authentication information. The receiving device checks whether the packets are sent by a trusted device or modified based on the authentication information.

Related Configuration

↘ **Configuring a Global Security Authentication Mechanism for NTP**

- By default, no NTP security authentication mechanism is enabled.
- Run the **ntp authenticate** command to enable the NTP security authentication mechanism.

↘ **Configuring a Global Authentication Key for NTP**

- By default, no global authentication key is configured.
- Run the **ntp authentication-key** command to enable an NTP global authentication key.

↘ **Configuring a Globally Trusted Key ID for NTP**

- By default, no globally trusted key is configured.
- Run the **ntp trusted-key** command to configure a device as the reference clock source to provide a trusted key for time synchronization externally.

↘ **Configuring a Trusted Key ID for an External Reference Clock Source**

- Run the **ntp server** command to specify an external reference source and the trusted key of this clock source as well.

3.3.3 NTP Access Control

Working Principle

Provide a minimum security measure by using an ACL.

Related Configuration

↘ **Configuring the Access Control Rights for NTP Services**

- By default, there is no access control right for NTP.
- Run the **ntp access-group** command to configure the access control rights for NTP.

3.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of NTP	 (Mandatory) It is used to enable NTP. After NTP is enabled, a device works in the external clock reference mode.	
	ntp server	Configures an NTP server.
	ntp update-calendar	Automatically updates a hardware clock.
	 (Optional) It is used to configure a device to the local clock reference mode.	
	ntp master	Configures the NTP master clock.
	 (Optional) It is used to disable NTP.	
	no ntp	Disables all functions of NTP and clears all NTP configurations.
Configuring NTP Security Authentication	 (Optional) It is used to prevent unreliable clock sources from performing time synchronization interference on a device.	
	ntp authenticate	Enables a security authentication mechanism.
	ntp authentication-key	Configures a global authentication key.
	ntp trusted-key	Configures a trusted key for time synchronization.
	ntp server	Configures a trusted key for an external reference clock source.
Configuring NTP Access Control	 (Optional) It is used to filter the sources of received NTP packets.	
	ntp access-group	Configures the access control rights for NTP.

3.4.1 Configuring Basic Functions of NTP

Configuration Effect

External Clock Reference Mode

- Use a device as a client to synchronize time from an external reference clock source to the local clock.
- After the time synchronization is successful, use the device as a time synchronization server to provide time synchronization.

Local Clock Reference Mode

- Use the local clock of a device as the NTP reference clock source to provide time synchronization.

Notes

- In the client/server mode, a device can be used as a time synchronization server to provide time synchronization only after successfully synchronizing time with a reliable external clock source.
- Once the local clock reference mode is configured, the system will not synchronize time with a clock source with a higher stratum.
- Configuring a local clock as the master clock (especially when specifying a lower stratum) may overwrite an effective clock source. If this command is used for multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.
- Before a local clock is configured as the master clock, if the system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the system time configuration section in the configuration guide.

Configuration Steps

▾ Configuring an NTP Server

- (Mandatory) At least one external reference clock source must be specified (A maximum of 20 different external reference clock sources can be configured).
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server.

▾ Automatically Updating a Hardware Clock

- Optional.
- By default, the system updates only the system clock, but not the hardware clock after successful time synchronization.
- After this command is configured, the system automatically updates the hardware clock after successful time synchronization.

▾ Configuring the NTP Master Clock

- To switch a device to the local clock reference mode, run this command.

▾ Disabling NTP

- To disable NTP and clear NTP configurations, run the **no ntp** command.
- By default, all interfaces can receive NTP packets after NTP is enabled. To disable NTP for a specified interface, run the **ntp disable** command.

Verification

- Run the **show ntp status** command to display the NTP configuration.

- Run the **show clock** command to check whether time synchronization is completed.

Related Commands

▾ Configuring an NTP Server

Command	ntp server [vrf <i>vrf-name</i>]{ <i>ip-addr</i> <i>domain</i> ip <i>domain</i> ipv6 <i>domain</i> }[version <i>version</i>][source <i>if-name</i>][key <i>keyid</i>][prefer]
Parameter Description	<p><i>vrf-name</i>: Indicates the name of the VRF that is bound to the reference clock source.</p> <p><i>ip-addr</i>: Indicates the IPv4/IPv6 address of the reference clock source.</p> <p><i>domain</i>: Indicates the IPv4/IPv6 domain name of the reference clock source.</p> <p><i>version</i>: Indicates the NTP version number, ranging from 1 to 3.</p> <p><i>if-name</i>: Indicates the interface type, including AggregatePort, Dialer GigabitEthernet, Loopback, Multilink, Null, Tunnel, Virtual-ppp, Virtual-template and Vlan.</p> <p><i>keyid</i>: Indicates the key used for communicating with the reference clock source, ranging from 1 to 4294967295.</p> <p>prefer: Indicates whether the reference clock source has a high priority.</p>
Command Mode	Global configuration mode
Usage Guide	<p>By default, no NTP server is configured. Nodexon client system supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the related key) to initiate encrypted communication with the servers.</p> <hr/> <p> If it is necessary to configure an authentication key, you must configure NTP security authentication before configuring an NTP server.</p> <hr/> <p>The default version of NTP for communicating with a server is NTP version 3. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.</p>

▾ Updating a Hardware Clock

Command	ntp update-calendar
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

▾ Configuring a Local Reference Clock Source

Command	ntp master [<i>stratum</i>]
Parameter Description	<i>stratum</i> : specifies the stratum of a local clock, ranging from 1 to 15. The default value is 8.
Command	Global configuration mode

Mode	
Usage Guide	N/A

↘ **Disabling NTP**

Command	no ntp
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command can be used to fast disable all functions of NTP and clear all NTP configurations.

↘ **Disabling Receiving of NTP Packets on an Interface**

Command	ntp disable
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

↘ **External Clock Reference Mode of NTP**

<p>Scenario</p> <p>Figure 3-5</p>	<ul style="list-style-type: none"> ● DEVICE-B is configured to the NTP external clock reference mode. ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
<p>Configuration Steps</p>	<ul style="list-style-type: none"> ● DEVICE-A configures the local clock as the NTP reference clock source. ● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
<p>DEVICE-A</p>	<pre>A#configure terminal A(config)# ntp master A(config)#exit</pre>
<p>DEVICE-B</p>	<pre>B#configure terminal B(config)# ntp server 192.168.1.1 B(config)# exit</pre>

DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show ntp status command on DEVICE-B to display the NTP configuration. ● DEVICE-B sends a time synchronization packet to 192.168.1.1 in order to synchronize time with DEVICE-A. ● After successfully synchronizing time with DEVICE-A, DEVICE-B can respond to the time synchronization request from DEVICE-C. ● Run the show clock command on DEVICE-B and DEVICE-C to check whether the time synchronization is successful.

Local Clock Reference Mode of NTP

Scenario Figure 3-6	
	<ul style="list-style-type: none"> ● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	<ul style="list-style-type: none"> ● DEVICE-B configures the local clock as the NTP reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<pre>B#configure terminal B(config)# ntp master B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show clock command on DEVICE-C to check whether the time synchronization is successful.

3.4.2 Configuring NTP Security Authentication

Configuration Effect

Synchronizing Time from a Trusted Reference Clock Source

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.

Providing Time Synchronization for a Trusted Device

Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

Notes

The authentication keys of the client and server must be the same.

Configuration Steps

▾ Configuring a Global Security Authentication Mechanism for NTP

- Mandatory.
- By default, a device disables the security authentication mechanism.

▾ Configuring a Global Authentication Key for NTP

- Mandatory.
- By default, a device is not configured with an authentication key.

▾ Configuring a Globally Trusted Key ID for NTP

- Optional.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID.
- Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.

▾ Configuring an Authentication Key ID for an External Reference Clock Source

- Optional.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID.
- Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.

Verification

- Run the **show run** command to verify the NTP configuration.
- Run the **show clock** command to check whether time is synchronized only with a trusted device.

Related Commands

▾ Enabling a Security Authentication Mechanism

Command	ntp authenticate
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	By default, a client does not use a global security authentication mechanism. If no security authentication

	mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that the communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must also be configured for initiating encrypted communication between the client and server.
--	---

↘ **Configuring a Global Authentication Key**

Command	<code>ntp authentication-key key-id md5 key-string [enc-type]</code>
Parameter Description	<p><i>key-id</i>: indicates the ID of a global authentication key, ranging from 1 to 4294967295.</p> <p><i>key-string</i>: indicates a key string.</p> <p><i>enc-type</i>: (optional) indicates whether an entered key is encrypted. 0 indicates no encryption, and 7 indicates simple encryption. The default setting is no encryption.</p>
Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Configuring a Trusted Key for NTP**

Command	<code>ntp trusted-key key-id</code>
Parameter Description	<i>key-id</i> : Indicates the ID of a trusted key, ranging from 1 to 4294967295.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ **Configuring a Trusted Key for an External Reference Clock Source**

Refer to the section “Related Commands”.

Configuration Example

↘ **Security Authentication**

Scenario Figure 3-7	
	<ul style="list-style-type: none"> ● DEVICE-B is configured to the NTP client/server mode and provides NTP services requiring security authentication for DEVICE-C. The authentication key is "abcd". ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	<ul style="list-style-type: none"> ● DEVICE-B configures DEVICE-A as the reference clock source. ● DEVICE-C configures DEVICE-B as the reference clock source.
DEVICE-B	<code>B#configure terminal</code>

	<pre>B(config)# ntp authentication-key 1 md5 abcd B(config)# ntp trusted-key 1 B(config)# ntp server 192.168.1.1 B(config)# exit</pre>
DEVICE-C	<pre>C#configure terminal C(config)# ntp authentication-key 1 md5 abcd C(config)# ntp server 192.168.2.1 key 1 C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● DEVICE-B sends a time synchronization packet that carries authentication information to 192.168.1.1 in order to synchronize time with DEVICE-A. ● Run the show clock command on DEVICE-B to check whether the time synchronization is successful.

3.4.3 Configuring NTP Access Control

Configuration Effect

Access control for NTP services provides a minimum security measure. A more secure method is to use an NTP authentication mechanism.

Notes

- Currently, the system does not support control query (used to control NTP servers by using network management devices, such as setting the leap second indicator or monitoring its working status). Though rule matching is implemented in the preceding sequence, no request related to control query is supported.
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.

Related Configuration

📄 Configuring the Access Control Rights for NTP

- Optional.
- Run the **ntp access-group** command to configure the access control rights and a corresponding ACL for NTP.

Verification

Run the **show run** command to verify the NTP configuration.

Related Commands

📄 Configuring the Access Control Rights for NTP Services

Command	<code>ntp access-group { peer serve serve-only query-only }access-list-number access-list-name</code>
Parameter Description	<p>peer: allows time request and control query for local NTP services, and allows a local device to synchronize time with a remote system (full access rights).</p> <p>serve: allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system.</p> <p>serve-only: allows only time request for local NTP services.</p> <p>query-only: allows only control query for local NTP services.</p> <p><i>access-list-number:</i> indicates the number of an IP ACL, ranging from 1 to 99 and from 1300 to 1999. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p> <p><i>access-list-name:</i> indicates the name of an IP ACL. For details about how to create an IP ACL, refer to the <i>Configuring ACL</i>.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Configure NTP access control rights.</p> <p>When an access request arrives, the NTP service matches rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is peer, serve, serve-only, and query-only.</p>

Configuration Example

Configuring NTP Access Control Rights

Configuration Steps	Allow only the device with the IP address of 192.168.1.1 to send a time synchronization request to a local device.
	<pre>Nodexon(config)# access-list 1 permit 192.168.1.1 Nodexon(config)# ntp access-group serve-only</pre>

3.5 Monitoring

Displaying

Description	Command
<code>show ntp status</code>	Displays the current NTP information.

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
<code>debug ntp</code>	Enables debugging.
<code>no debug ntp</code>	Disables debugging.

4 Configuring SNTP

4.1 Overview

The Simple Network Time Protocol (SNTP) is a simplified version of Network Time Protocol (NTP), which is used to synchronize the clocks of computers on the Internet. SNTP is applied in scenarios where it is unnecessary to use all NTP functions.

NTP uses a complex algorithm and has higher requirements for the system whereas SNTP uses a simpler algorithm and provides higher performance. Generally, SNTP precision can reach about 1s, which meets the basic requirements of most scenarios. Since SNTP packets are the same as NTP packets, the SNTP client implemented on a device is fully compatible with an NTP server.

Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

4.2 Applications

Application	Description
Synchronizing Time with an NTP Server	A device is used as a client to synchronize time with an NTP server.

4.2.1 Synchronizing Time with an NTP Server

Scenario

As shown in Figure 4-1, DEVICE-B uses a local clock as the NTP clock reference source and provides time synchronization for DEVICE-C.

DEVICE-C is used as an SNTP client to synchronize time with DEVICE-B.

Figure 4-1

Deployment

- Specify DEVICE-B as the SNTP server of DEVICE-C.
- Enable SNTP for DEVICE-C.

4.3 Features

Basic Concepts

SNTP Packet

SNTPV4 is developed from NTP, which is intended to simplify the functions of NTP. It does not change the NTP specifications and the original implementation of NTP. The message format of SNTPV4 is the same as that of NTP defined in RFC1305, with only some data fields initialized into preset values.

As defined in RFC1305, SNTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 4-2 shows the format of an SNTP time synchronization packet.

Figure 4-2 Format of an SNTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.
-
- **i** 00: indicates no warning information; 01: indicates that there are 61 seconds in the previous minute; 10: indicates that there are 59 seconds in the previous minute; 11: indicates that the clock is not synchronized.
-
- Version Number(VN): indicates a 3-bit NTP/SNTP version number. The current version number is 3.
 - Mode: indicates a 3-bit SNTP/NTP working mode.
-
- **i** 0: indicates no definition; 1: indicates symmetric active; 2: indicates symmetric passive; 3: indicates a client; 4: indicates a server; 5: indicates broadcasting; 6: indicates control information; 7: reserved.
-
- Stratum: indicates the 8-bit stratum of a local clock. 0: indicates no definition; 1: indicates the master clock reference source; other values: indicate slave clock reference sources.
 - Poll Interval: indicates the poll interval (seconds), which is a 8-bit integer.
 - Precision: indicates the time precision (seconds) of a local clock, which is a 8-bit integer.

- Root Delay: indicates the round-trip time to the master clock reference source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

Overview

Feature	Description
SNTP Time Synchronization	Synchronizes time from an SNTP/NTP server to a local device.

4.3.1 SNTP Time Synchronization

Working Principle

SNTP time synchronization is implemented by interaction of SNTP/NTP packets between a client and a server. The client sends a time synchronization packet to the server at intervals (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

Figure 4-3 shows the format of an SNTP time synchronization packet.

Figure 4-3 Working Principle of SNTP

DEVICE-B (B for short) is used as an NTP reference clock source, DEVICE-A (A for short) is used as an SNTP client that synchronizes time with DEVICE-B. At a time point, the local clock of A is 19:00:00 and the local clock of B is 19:30:20.

1. A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from A is 19:00:00 and is filled in Originate Timestamp.
2. After a 2-second network delay, the local time (T1) when B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
3. B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from B is 19:30:24 and is filled in Transmit Timestamp.
4. After a 2-second network delay, A receives the response packet. The local time (T3) when the response packet arrives at A is 19:00:06.

The specific calculations for time synchronization are as follows:

- A obtains the time difference of 30 minutes and 20 seconds between B and A by using the formula $((T1-T0)+(T2-T3))/2$.
- A obtains the packet round-trip delay of four seconds between A and B by using the formula $(T3-T0)-(T2-T1)$.

Related Configuration

▾ Enabling SNTP

- SNTP is disabled by default.
- Run the **sntp enable** command to enable SNTP.

▾ Configuring an SNTP Server

- By default, no SNTP server is configured.
- Run the **sntp server** command to specify an SNTP server.

▾ Configuring the SNTP Time Synchronization Interval

- By default, the SNTP time synchronization interval is 1,800s.
- Run the **sntp interval** command to specify the time synchronization interval.

4.4 Configuration

Configuration	Description and Command	
Configuring SNTP	 (Mandatory) It is used to enable SNTP.	
	sntp enable	Enables SNTP.
	sntp server	Configures the IP address of an SNTP server.
	 (Optional) It is used to configure the SNTP time synchronization interval.	

Configuration	Description and Command	
	sntp interval	Configures the SNTP time synchronization interval.

4.4.1 Configuring SNTP

Configuration Effect

An SNTP client accesses an NTP server at fixed intervals to correct the clock regularly.

Notes

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

Configuration Steps

↳ Enabling SNTP

- (Mandatory) SNTP is disabled by default.

↳ Configuring the IP address of an SNTP Server

- (Mandatory) No SNTP/NTP server is configured by default.

↳ Configuring the SNTP Time Synchronization Interval

- Optional.
- By default, a device synchronizes time every half an hour.

Verification

Run the **show sntp** command to display SNTP-related parameters.

Related Commands

↳ Enabling SNTP

Command	sntp enable
Parameter	N/A
Description	
Command Mode	Global configuration mode
Usage Guide	SNTP is disabled by default. Run the no sntp enable global configuration command to disable SNTP.

↳ Configuring the IP address of an SNTP Server

Command	sntp server [oob] { ip- address domain }
----------------	---

Parameter Description	<p><i>ip-address</i>: indicates the IP address of an SNTP server. No SNTP server is configured by default.</p> <p><i>domain</i>: domain name of the SNTP server. No SNTP server is configured by default.</p> <p>oob: Indicates that the SNTP server supports an out-band management interface.</p>
Command Mode	Global configuration mode
Usage Guide	<p>Since SNTP is fully compatible with NTP, the server can be configured as a public NTP server on the Internet.</p> <p>Since SNTP packets are the same as NTP packets, the SNTP client is fully compatible with the NTP server. There are many NTP servers on the Internet. You can select an NTP server with a shorter delay as the SNTP server on your device.</p>

↘ **Configuring the SNTP Time Synchronization Interval**

Command	sntp interval <i>seconds</i>
Parameter Description	<i>seconds</i> : Indicates the time synchronization interval, ranging from 60s to 65,535s. The default value is 1,800s.
Command Mode	Global configuration mode
Usage Guide	<p>Run this command to set the interval for an SNTP client to synchronize time with an NTP/SNTP server.</p> <p> The interval configured here does not take effect immediately. To make it take effect immediately, run the sntp enable command.</p>

Configuration Example

↘ **SNTP Time Synchronization**

Scenario Figure 4-4	
	<ul style="list-style-type: none"> ● DEVICE-B indicates an NTP server on the Internet. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	Enable SNTP for DEVICE-C and configure DEVICE-B as an NTP server.
DEVICE-C	<pre>C#configure terminal C(config)# sntp server 192.168.2.1 C(config)# sntp enable C(config)# exit</pre>
Verification	<ul style="list-style-type: none"> ● Run the show clock command on DEVICE-C to check whether the time synchronization is successful. ● Run the show sntp command on DEVICE-C to display the SNTP status and check whether the server is successfully configured.

4.5 Monitoring

Displaying

Description	Command
<code>show sntp</code>	Displays SNTP-related parameters.

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
<code>debug sntp</code>	Enables debugging.

5 Configuring SPAN-RSPAN

5.1 Overview

The Switched Port Analyzer (SPAN) is to copy packets of a specified port to another switch port that is connected to a network monitoring device, so as to achieve network monitoring and troubleshooting.

All input and output packets of a source port can be monitored through SPAN. For example, as shown in the following figure, all packets on Port 5 are mapped to Port 10, and the network analyzer connected to Port 10 receives all packets that pass through Port 5.

Figure 5-1 SPAN Configuration Instance

The SPAN function is mainly applied in network monitoring and troubleshooting scenarios, to monitor network information and rectify network faults.

The Remote SPAN (RSPAN), an extension to SPAN, is capable of remotely monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port. Users can observe data packets of the remote mirrored port by using an analyzer in the central equipment room.

The application scenarios of RSPAN are similar to those of SPAN. RSPAN allows users to conduct real-time data monitoring without staying in the equipment room, providing great convenience for users.

VLAN SPAN (VSPAN) considers data streams of some VLANs as data sources and mirrors them to a destination port. The configuration is similar to that of the port-based SPAN. VSPAN has the following features:

- A VLAN that is not a remote VLAN can be specified as the data source of VSPAN.
- Some VLANs that are not remote VLANs can be specified as the data sources of VSPAN.
- When a VLAN is configured as a data source, packets only in the Rx direction can be mirrored.

5.2 Applications

Application	Description
Stream-based SPAN	Data streams with certain characteristics need to be monitored, for example, data streams using a specified access control list (ACL) policy need to be monitored.
One-to-Many RSPAN	Multiple users need to monitor data of the same port.
RSPAN Basic Applications	Packets on the mirroring source device need to be mirrored to the destination device for monitoring.

5.2.1 Stream-based SPAN

Scenario

As shown in the following figure, the network analyzer can be configured to can monitor all data streams forwarded by Switch A to Switch B and specific data streams of Switch B (for example, data streams from PC1 and PC2).

Figure 5-2 SPAN Simple Application Topology

Remarks	0000.0000.0001 is the MAC address of PC1. 0000.0000.0002 is the MAC address of PC2.
----------------	--

Deployment

- In the preceding figure, configure the SPAN function on Switch A connected to the network analyzer, set port Gi 0/1 connected to Switch B as the SPAN source port, and set port Gi 0/2 that is directly connected to the network analyzer as the SPAN destination port.
- Configure stream-based SPAN (only data streams of PC1 and PC2 are allowed) for the source port Gi 0/1 of SPAN.

5.2.2 One-to-Many RSPAN

Scenario

As shown in the following figure, one-to-many RSPAN can be implemented on a single device, that is, both PC 1 and PC 2 can be configured to monitor the transmitted and received traffic of the port connected to the server. Users can make proper configuration (for example, remote VLAN and port MAC loopback) to monitor data streams that pass through port Gi 4/1 on PC 1 and PC 2, thereby monitoring data streams of the server.

Figure 5-3 Application Topology of One-to-Many RSPAN

Deployment

- Create a remote VLAN on Switch A.
- Configure Switch A as the source device of RSPAN and configure the port Gi 4/1 that is directly connected to the server as the RSPAN source port. Select a port that is in the Down state, Gi 4/2 in this example, as the RSPAN output port, add this port to the remote VLAN, and configure MAC loopback (run the **mac-loopback** command in interface configuration mode).
- Add ports that are directly connected to PC 1 and PC 2 to the remote VLAN.

5.2.3 RSPAN Basic Applications

Scenario

As shown in the following figure, the RSPAN function enables the network analyzer to monitor the STA connected to the source device Switch A from the destination device Switch C through the intermediate device Switch B. The devices can normally exchange data with each other.

Figure 5-4 Basic Application Topology of RSPAN

Deployment

- Configure a remote VLAN on Switch A, Switch B, and Switch C.
- On Switch A, configure port Gi 0/1 directly connected to the STA as the source port, configure port Gi 0/2 connected to Switch B as the output port, and configure the switching function for the output port.
- On Switch B, configure port Gi 0/1 connected to Switch A and port Gi 0/2 connected to Switch C as common ports.
- On Switch C, configure port Gi0/1 connected to Switch B as a common source port, configure port Gi 0/2 connected to the network analyzer as the RSPAN destination port, and configure the switching function for the RSPAN destination port.

5.3 Features

Basic Concepts

▾ SPAN Session

A SPAN session is data streams between the SPAN source port and the destination port, which can be used to monitor the packets of one or more ports in the input, output, or both directions. Switched ports, routed ports, and aggregate ports (APs) can be configured as source ports or destination ports of SPAN sessions. Normal operations on a switch are not affected after ports of the switch are added to a SPAN session.

Users can configure a SPAN session on a disabled port but the SPAN session is inactive. A SPAN session is in the active state only after the port on which the SPAN session is configured is enabled. In addition, a SPAN session does not take effect after a switch is powered on. It is active only after the destination port is in the operational state. Users can run the **show monitor [session session-num]** command to display the operation status of a SPAN session.

▾ SPAN Data Streams

A SPAN session covers data streams in three directions:

- Input data streams: All packets received by a source port are copied to the destination port. Users can monitor input packets of one or more source ports in a SPAN session. Some input packets of a source port may be discarded for some reasons (for example, for the sake of port security). It does not affect the SPAN function and such packets are still mirrored to the destination port.

- **Output data streams:** All packets transmitted by a source port are copied to the destination port. Users can monitor output packets of one or more source ports in a SPAN session. Packets transmitted from other ports to a source port may be discarded for some reasons and such packets will not be transmitted to the destination port. The format of output packets of a source port may be changed for some reasons. For example, after routing, packets transmitted from the source port are changed in source MAC addresses, destination MAC addresses, VLAN IDs, and TTLs, and their formats are also changed after copied to the destination port.
- **Bidirectional data streams:** Bidirectional data streams include input data streams and output data streams. In a SPAN session, users can monitor data streams of one or more source ports in the input and output directions.

↳ Source Port

A source port is called a monitored port. In a SPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single SPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not restricted.

A source port has the following features:

- A source port can be a switched port, routed port, or AP.
- A source port cannot be used as a destination port simultaneously.
- A source port and a destination port can belong to the same VLAN or different VLANs.

↳ Destination Port

A SPAN session has one destination port (called a monitoring port) for receiving packets copied from a source port.

A destination port has the following features:

- A destination port can be a switched port, routed port, or AP.
- A destination port cannot be used as a source port simultaneously.

Overview

Feature	Description
SPAN	Configures mirroring of ports on the same device.
RSPAN	Configures mirroring of ports on different devices.

5.3.1 SPAN

SPAN is used to monitor data streams on switches. It copies frames on one port to another switch port that is connected to a network analyzer or RMON analyzer so as to analyze the communication of the port.

Working Principle

When a port transmits or receive packets, SPAN, after checking that the port is configured as a SPAN source port, copies the packets transmitted and received by the port to the destination port.

↳ Configuring a SPAN Source Port

Users need to specify a SPAN session ID and source port ID to configure a SPAN source port, and set the optional SPAN direction item to determine the direction of SPAN data streams or specify an ACL policy to mirror specific data streams.

▾ Configuring a SPAN Destination Port

Users need to specify a SPAN session ID and destination port ID to configure a SPAN destination port, and set the optional switching function item to determine whether to enable the switching function and tag removal function on the SPAN destination port.

Related Configuration

The SPAN function is disabled by default. It is enabled only after a session is created, and the SPAN source and destination ports are configured. A SPAN session can be created when a SPAN source port or destination port is configured.

▾ Configuring a SPAN Source Port

A SPAN session does not have a SPAN source port by default. Users can run the following command to configure a SPAN source port:

```
monitor session session-num source interface interface-id [ both | rx | tx ] [ acl name ]
```

In the preceding command:

session-num: Indicates the SPAN session ID. The number of supported SPAN sessions varies with products.

interface-id: Indicates the SPAN source port to be configured.

rx: Indicates that only packets received by the source port are monitored after **rx** is configured.

tx: Indicates that only packets transmitted by the source port are monitored after **tx** is configured.

both: Indicates that packets transmitted and received by the source port are copied to the destination port for monitoring after **both** is configured, that is, **both** includes **rx** and **tx**. If none of **rx**, **tx**, and **both** is selected, **both** is enabled by default.

acl: Specifies an ACL policy. After this option is configured, packets allowed by the ACL policy on the source port are monitored. This function is disabled by default.

▾ Configuring a SPAN Destination Port

A SPAN session does not have a SPAN destination port by default. Users can run the following command to configure a SPAN destination port:

```
monitor session session-num destination interface interface-id [ switch ]
```

In the preceding command:

switch: Indicates that the SPAN destination port only receives packets mirrored from the SPAN source port and discards other packets if this option is disabled, and receives both packets mirrored from the SPAN source port and packets from non-source ports if this option is enabled, that is, the communication between this destination port and other devices is not affected.

When the SPAN destination port is configured, the relevant function is disabled by default if **switch** is not configured.

▾ Configuring Stream-based SPAN

This function is disabled by default. Users can run the **monitor session session-num source interface interface-id [rx] acl acl-name** command to configure stream-based SPAN.

Pay attention to the following points when using SPAN:

-  The SPAN destination port is used for the Spanning Tree Protocol (STP) calculation.
-  SPAN is unavailable if a source port or destination port is disabled.
-  If a source port or destination port is added to an AP, the source port or destination port exits from a SPAN session.
-  If a VLAN (or VLAN list) is used as a SPAN source, ensure that the destination port has sufficient bandwidth for receiving mirrored data of the VLAN (or VLAN list).
-  Not all products support all options of the preceding commands because of product differences.

5.3.2 RSPAN

RSPAN is capable of monitoring multiple devices. Each RSPAN session is established in a specified remote VLAN. RSPAN breaks through the limitation that a mirrored port and a mirroring port must reside on the same device, and allows a mirrored port to be several network devices away from a mirroring port.

Working Principle

A remote VLAN is created for the source device, intermediate device, and destination device, all ports involved in an RSPAN session need to be added to the remote VLAN. Mirrored packets are broadcasted in the remote VLAN so that they are transmitted from the source port of the source switch to the destination port of the destination switch.

↘ **Configuring a Remote VLAN**

Packets from an RSPAN source port are broadcasted in a remote VLAN so as to be copied from the local switch to the remote switch. The RSPAN source port, output port, reflection port, transparent transmission ports of the intermediate device (packet input port and output port of the intermediate device), destination port and input port of the destination port must be added to the remote VLAN. The RSPAN function requires configuring a VLAN as a remote VLAN in VLAN mode.

↘ **Configuring an RSPAN Session**

The configuration of the RSPAN source port and destination port are similar to that of the SPAN source port and destination port, but the mirroring session ID specified during configuration must be the ID of an RSPAN session.

↘ **Configuring an RSPAN Source Port**

The configuration of an RSPAN source port is the same as that of a SPAN source port, but the specified mirroring session ID must be the ID of an RSPAN session.

↘ **Configuring an RSPAN Output Port**

The output port is located on the source device and must be added to a remote VLAN. Mirrored packets of a source port are broadcasted in this remote VLAN. The source device transmits packets to the intermediate switch or destination switch through the output port.

↘ Configuring an RSPAN Destination Port

When an RSPAN destination port is configured, an RSPAN session ID, remote VLAN, and port name must be specified so that packets from the source port are copied to the destination port through the remote VLAN.

↘ Configuring Stream-based RSPAN

RSPAN is an extension to SPAN and also supports stream-based mirroring. The configuration is the same as that of stream-based SPAN. Stream-based RSPAN does not affect normal communication.

Users can configure an ACL in the input direction of a source port on an RSPAN source device. Standard ACLs, extended ACLs, MAC ACLs, and user-defined ACLs are supported.

Users can configure a port ACL in the input direction of a source port on an RSPAN source device, and configure a port ACL in the output direction of the destination port on the RSPAN destination device. Users can also configure an ACL in the output direction of a remote VLAN on an RSPAN source switch and configure an ACL in the input direction of the remote VLAN on the RSPAN destination switch.

↘ Configuring One-to-Many RSPAN

If data streams of one source port need to be mirrored to multiple destination ports, users can configure an RSPAN session, configure the source port of the RSPAN session as a one-to-many mirroring source port and select another Ethernet port as the forwarding port (output port on the source device). In addition, the MAC loopback function needs to be configured on the RSPAN forwarding port in interface configuration mode, the expected RSPAN output port and RSPAN forwarding port need to be added to the remote VLAN. Then, mirrored packets are looped back on the RSPAN forwarding port and then broadcasted in the remote VLAN, thereby implementing one-to-many RSPAN.

Related Configuration

The RSPAN function is disabled by default. It is enabled only after an RSPAN session is created, and a remote VLAN, RSPAN source port, and RSPAN destination port are configured.

↘ Configuring a Remote VLAN

No remote VLAN is specified for RSPAN by default. Users can run the **remote-span** command in VLAN mode to configure a VLAN as a remote VLAN. One remote VLAN corresponds to one RSPAN session.

↘ Configuring an RSPAN Source Device

This function is disabled by default. Users can run the **monitor session session-num remote-source** command in global configuration mode to configure a device as the remote source device of a specified RSPAN session.

↘ Configuring an RSPAN Destination Device

This function is disabled by default. Users can run the **monitor session session-num remote-destination** command in global configuration mode to configure a device as the remote destination device of a specified RSPAN session.

↘ Configuring an RSPAN Source Port

A source port of an RSPAN session is configured on the source device. The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified. This function is disabled by default.

↘ **Configuring an Output Port on the RSPAN Source Device**

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure an output port on the RSPAN source device. If the option **switch** is configured, the output port can participate in normal data packet switching. It is not configured by default. The output port must be added to a remote VLAN.

↘ **Configuring a Destination Port on the RSPAN Destination Device**

This function is disabled by default. Users can run the **monitor session session-num destination remote vlan remote-vlan interface interface-name [switch]** command in global configuration mode to configure a destination port on the RSPAN destination device. If the option **switch** is configured, the destination port can participate in normal data packet switching. It is not configured by default. The destination port must be added to a remote VLAN.

Pay attention to the following points when using RSPAN:

-  A remote VLAN must be configured on each device, their VLAN IDs must be consistent, and all ports that participate in a session must be added to the VLAN.
-  It is not recommended that common ports be added to a remote VLAN.
-  Do not configure a port that is connected to an intermediate switch or destination switch as an RSPAN source port. Otherwise, traffic on the network may be in chaos.

5.4 Configuration

Configuration	Description and Command	
Configuring SPAN Basic Functions	 (Mandatory) It is used to create SPAN.	
	monitor session session-num source interface interface-id [both rx tx]	Configures a SPAN source port.
	monitor session session-num destination interface interface-id [switch]	Configures a SPAN destination port.
	monitor session session-num source interface interface-id rx acl acl-name	Configures stream-based SPAN.
	monitor session session-num source vlan vlan-id [rx]	Specifies a VLAN as the data source of SPAN.
	monitor session session-num source filter vlan vlan-id-list	Specifies some VLANs as the data sources of SPAN.
Configuring	 (Mandatory) It is used to create RSPAN.	

RSPAN Basic Functions	monitor session <i>session-num</i> remote-source	Configures an RSPAN session ID and specifies a source device.
	monitor session <i>session-num</i> remote-destination	Configures an RSPAN session ID and specifies a destination device.
	remote-span	Configures a remote VLAN.
	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]	Configures an RSPAN source port.
	monitor session <i>session-num</i> destination remote vlan <i>remote-vlan-id</i> interface <i>interface-id</i> [switch]	Configures an output port on the RSPAN source device or a destination port on the RSPAN destination device.

5.4.1 Configuring SPAN Basic Functions

Configuration Effect

- Configure a source and destination ports for a SPAN session.
- Configure a destination port to monitor any packets transmitted and received by a source port.

Notes

- If a source port or destination port is added to an AP, the source port or destination port exits from a SPAN session.
- If the switch function is disabled on a SPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switch function is enabled, the destination port can receive non-mirrored packets.

Configuration Steps

▾ [Configuring a SPAN Session](#)

- Global configuration mode. Mandatory.
- You can configure a SPAN session when configuring a SPAN source port or destination port, or when configuring a specified VLAN or some VLANs as a data source or data sources of SPAN.

▾ [Configuring a SPAN Source Port](#)

- Global configuration mode. Mandatory.
- You can select the SPAN direction when configuring a SPAN source port. The **both** direction is configured by default, that is, both transmitted and received packets are monitored.

↘ Configuring a SPAN Destination Port

Global configuration mode. Mandatory.

A SPAN session is active only when a SPAN source port is configured (or a VLAN is specified as the data source of SPAN) and a SPAN destination port is configured.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. Alternatively, conduct packet capture analysis on the SPAN destination port and check whether the SPAN function takes effect according to the captured packets.

Related Commands

↘ Configuring a SPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx]
Parameter	<i>session-num</i> : Indicates the ID of a SPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring a SPAN Destination Port

Command	monitor session <i>session-num</i> destination interface <i>interface-id</i> [switch]
Parameter	<i>session-num</i> : Indicates the ID of a SPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. switch : Indicates that the switching function is enabled on the SPAN destination port. It is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring Stream-based SPAN

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> rx acl <i>acl-name</i>
Parameter	<i>session-num</i> : Indicates the ID of a SPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. <i>acl-name</i> : Indicates an ACL name.
Command Mode	Global configuration mode

- A remote VLAN must be created on an intermediate device and transparent transmission ports must be added to the remote VLAN.

Configuration Steps

↘ Configuring an RSPAN Session

- Global configuration mode. Mandatory.
- The same session ID needs to be configured on the RSPAN source device and RSPAN destination device.

↘ Configuring an RSPAN Source Device

- Global configuration mode. Mandatory.
- It is used to specify a device to be monitored by RSPAN.

↘ Configuring an RSPAN Destination Device

- Global configuration mode. Mandatory.
- It is used to specify the destination device for outputting RSPAN packets.

↘ Configuring an RSPAN Source Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, RSPAN monitoring can be conducted on packets of the RSPAN source port. You can specify RSPAN to monitor remote VLAN packets in the input direction, output direction, or both directions of the RSPAN source port.

↘ Configuring an RSPAN Output Port

- Global configuration mode. Mandatory.
- Complete the configuration on an RSPAN source device. After configuration, mirrored packets received by the ports added to the remote VLAN can be transmitted to the RSPAN destination device through the output port.

↘ Configuring an RSPAN Destination Port

- Global configuration mode. Mandatory.
- Complete the configuration on the RSPAN destination device. After configuration, the RSPAN destination device forwards mirrored packets received by the ports added to the remote VLAN to the monitoring device through the destination port.

Verification

- Run the **show monitor** command or the **show running** command to check whether RSPAN is successfully configured on each device, or conduct packet capture on the destination mirroring port on the RSPAN destination device to check whether packets mirrored from the source port of the RSPAN source device are captured.

Related Commands

↘ Configuring an RSPAN Source Device

Command	monitor session <i>session-num</i> remote-source
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring an RSPAN Destination Device

Command	monitor session <i>session-num</i> remote-destination
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring a Remote VLAN

Command	remote-span
Parameter	N/A
Description	
Command Mode	VLAN mode
Usage Guide	N/A

↘ Configuring an RSPAN Source Port

Command	monitor session <i>session-num</i> source interface <i>interface-id</i> [both rx tx][acl <i>acl-name</i>]
Parameter	<i>session-num</i> : Indicates the ID of an RSPAN session.
Description	<i>interface-id</i> : Indicates the interface ID. both : Indicates that packets in the input and output directions are monitored. It is the default value. rx : Indicates that packets in the input direction are monitored. tx : Indicates that packets in the output direction are monitored. <i>acl-name</i> : Indicates an ACL name.
Command Mode	Global configuration mode
Usage Guide	The configuration is the same as that of a SPAN source port but an RSPAN session ID needs to be specified.

↘ Configuring an Output Port on the RSPAN Source Device

	<pre>Remote vlan 7 mtp_switch on</pre>
C	<pre>Nodexon# show monitor sess-num: 1 span-type: DEST_SPAN dest-intf: FastEthernet 0/2 Remote vlan 7 mtp_switch on</pre>

Common Errors

- A remote VLAN must be configured on the source device, intermediate device, and destination device, and their VLAN IDs must be consistent.
- Packet loss may occur if packets of a port with large bandwidth are mirrored to a port with small bandwidth.
- One MAC loopback port and multiple output ports need to be configured to implement one-to-many RSPAN.

5.5 Monitoring

Displaying

Description	Command
Displays all mirroring sessions existing in the system.	show monitor
Displays a specified mirroring session.	show monitor session <i>session-id</i>

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	debug span

6 Configuring ERSPAN

6.1 Overview

Encapsulated Remote Switched Port Analyzer (ERSPAN) is an extension to Remote Switched Port Analyzer (RSPAN). SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

An ERSPAN encapsulates all SPAN packets into IP packets through a generic routing encapsulation (GRE) tunnel, and routes them to the destination port of an RSPAN device. The following figure shows the topology of a typical application:

Figure 6-1 Topology of a Typical ERSPAN Application

There are two kinds of roles played by the devices in the figure:

- Source switch: A source switch refers to the switch where the ERSPAN source port resides. It copies the packets on the source port, outputs the copies from the output port, encapsulates them into IP packets, and forwards the IP packets to the destination switch.
- Destination switch: A destination switch refers to the switch where the ERSPAN destination port resides. It puts the received SPAN packets through the SPAN destination port, decapsulates them into GRE packets, and then forwards the GRE packets to the monitoring device.

To implement ERSPAN, the GRE-encapsulate IP packets must be able to be normally routed to the destination SPAN device.

6.2 Applications

Application	Description
Basic ERSPAN Applications	Packets on the SPAN source device need to be mirrored to the destination device for monitoring.

6.2.1 Basic ERSPAN Applications

Scenario

As shown in the following figure, ERSPAN enables the network analyzer to monitor the users connected to the source device Switch A. The devices can normally exchange data with each other.

Figure 6-2 Topology of Basic ERSPAN Applications

Deployment

- On Switch A, configure the port directly connected to users (Gi 0/1) as a source port, and configure the port connected to Switch B (Gi 0/2) as an output port.
- On Switch B, the ports connected to Switch A and Switch C (Gi 0/1 and Gi 0/2) are respectively member interfaces of switch virtual interface (SVI) interfaces of two network segments, ensuring interworking between the two IP network segments.

6.3 Features

Basic Concepts

↳ ERSPAN Session

SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, ERSPAN mirroring allows SPAN packets to be transmitted between routing networks. An ERSPAN encapsulates all SPAN packets into IP packets through a GRE tunnel, and routes them to the destination port of an RSPAN device. An ERSPAN can monitor input, output, and bidirectional packets of one or more ports. Ports such as a switched port, routed port and aggregate port (AP) can be configured as a source port for an ERSPAN session. The switch is not affected after the port is added to an ERSPAN session.

↳ Source Port

A source port is also called a monitored port. In an ERSPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single ERSPAN session, users can monitor the input, output, and bidirectional data streams, and the number of source ports is not limited. A source port has the following features:

- A source port can be a switched port, routed port, or an AP.
- It supports mirroring of multiple source ports on the source device to the designated output ports.
- The source port and output port cannot be on the same port; when the SPAN source port is a Layer-3 interface, both Layer-2 and Layer-3 packets are monitored.
- When multiple ports are bidirectionally monitored, a packet is input from a port and output from the other. Such monitoring is considered correct if only one packet is monitored.
- When the status of enabled Spanning Tree Protocol (STP) port is in block state, the input and output packets on the port can be monitored;
- Source port and destination port can belong to the same VLAN or different VLANs.

Overview

Feature	Description
ERSPAN	Configures SPAN on different Internet ports.

6.3.1 ERSPAN

Encapsulated ERSPAN is an extension of RSPAN. SPAN data packets of common RSPANs can be transmitted only within Layer 2 and cannot pass through routing networks. However, an ERSPAN can transmit SPAN packets between routing networks.

Working Principle

All the mirrored packets are encapsulated into IP packets through a GRE tunnel, and routed to the destination port of an RSPAN device.

↳ Configuring an ERSPAN Session

Configure ERSPAN of the switch, and distinguish between attributes of ERSPAN switch of the device. You need to designate an ERSPAN session ID, and enter the ERSPAN configuration mode after configuration succeeds.

↳ Configuring a Source Port

After entering the ERSPAN configuration mode, you need to name the source port to configure the SPAN source port, and determine the direction of SPAN data streams according to optional configurations of SPAN direction.

↳ Enabling an ERSPAN Session

By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

↳ Encapsulating the Origin IP Address

Encapsulating an origin IP address aims to configure the origin IP address of an encapsulated GRE packet.

↳ Encapsulating the Destination IP Address

Encapsulating a destination IP address aims to configure the destination IP address of an encapsulated GRE packet and ensure normal routing of SPAN packets on the network.

↳ Encapsulating IP TTL/DSCP

Encapsulate Time to Live (TTL) and Differentiated Services Code Point (DSCP) values of IP packets.

↳ `vrf vrf-name`

It indicates the name of virtual routing. Different virtual routing values might obtain different egresses for the same destination IP.

Related Configuration

By default, an SPAN is disabled. It is enabled only after a session is created, and source SPAN port, origin IP and destination IP addresses are configured.

↳ Configuring an ERSPAN Session

```
Nodexon(config)# monitor session session_num erspan-source
```

Wherein,

session-num: Indicates that the number of SPAN sessions supported by SPAN session IDs varies with products.

↳ Configuring a Source Port

```
Nodexon(config-mon-erspan-src)# source interface single_interface {[rx | tx | both]}
```

Wherein,

single_interface: Indicates the SPAN source port to be configured.

rx: Indicates that only the packets received by the source port are monitored after **rx** is configured.

tx: Indicates that only the packets sent from the source port are monitored after **tx** is configured.

both: Indicates that after **both** is configured, the packets sent and received by the source port are transmitted to the destination port to be monitored; that is to say, **both** includes **rx** and **tx**. If none of **rx**, **tx**, or **both** is configured, **both** is enabled by default.

↳ Configuring Stream-based SPAN

The function is disabled by default. Run the `Nodexon(config-mon-erspan-src)# source interface interface-id rx acl acl-name` command to configure stream-based SPANs.

↳ Enabling an ERSPAN Session

```
Nodexon (config-mon-erspan-src)# shutdown
```

This command is used to disable ERSPAN mirroring. (By default) Run the **no shutdown** command to enable ERSPAN mirroring.

↘ Encapsulating the Destination IP Address

Nodexon(config-mon-erspan-src)# **destination ip address** *ip-address*Wherein,
ip-address: Encapsulates the destination IP address.

↘ Encapsulating the Origin IP Address

Nodexon(config-mon-erspan-src)# **origin ip address** *ip-address*Wherein,
ip-address: Encapsulates the origin IP address.

↘ Encapsulating IP TTL

Nodexon(config-mon-erspan-src)# **ip ttl** *ttl_value*Wherein,
ttl_value: Configures the TTL value of an encapsulated IP address. The TTL value ranges from 0 to 255, and the default value is 64.

↘ Encapsulating IP DSCP

Nodexon(config-mon-erspan-src)# **ip dscp** *dscp_value*Wherein,
dscp_value: Configures the DSCP value of an encapsulated IP address. The DSCP value ranges from 0 to 63, and the default value is 0. The function takes effect only after trusting DSCP is configured on the SPAN source port.

↘ Encapsulating vrf *vrf-name*

Nodexon(config-mon-erspan-src)# **vrf** *vrf-name*Wherein,
vrf-name: Indicates the name of VPN Routing & Forwarding Instance (VRF).

 Pay attention to the following issues during use:

- Confirm the Layer-3 routing connectivity from source switch to destination switch.
- ERSPAN is unavailable if a source port is disabled.
- If a source port or destination port is added to an AP, the source port or destination port egresses an ERSPAN session.
- As a result of product differences, not all products support all options of the above-mentioned commands.

6.4 Configuration

Configuration	Description and Command
---------------	-------------------------

Configuring Basic ERSPAN Functions	 (Mandatory) It is used to create ERSPAN mirroring.	
	monitor session <i>erspan_source_session_number</i> erspan-source	Configures an ERSPAN session ID, and enters the configuration mode of the source ERSPAN device.
	source interface <i>single_interface</i> {[rx tx both]}	Associates the source ERSPAN port, and selects an SPAN direction.
	source interface <i>single_interface</i> rx acl <i>acl-name</i>	Configures the stream-based SPAN source for ERSPAN.
	shutdown	Disables ERSPAN mirroring.
	destination ip address <i>ip_address</i>	Configures the destination IP address for an ERSPAN stream. The address must be the interface address of the destination device.
	original ip address <i>ip_address</i>	Configures the encapsulated origin IP address for ERSPAN.
	ip ttl <i>tth_value</i>	(Optional) Configures the TTL value of an encapsulated IP address for ERSPAN.
	ip dscp <i>dscp_value</i>	(Optional) Configures the DSCP field value of an encapsulated IP address for ERSPAN.
	vrf <i>vrf_name</i>	(Optional) Configures the VRF name.

6.4.1 Configuring Basic ERSPAN Functions

Configuration Effect

- RSPAN enables a network analyzer to monitor users.
- Devices can normally exchange data with each other.

Notes

- If a source port is added to an AP, the source port egresses an ERSPAN session.
- The Layer-3 routing connectivity from source switch to destination switch must be ensured.

Configuration Steps

↳ ERSPAN Session

- Global configuration mode. Mandatory.
- The session ID configured with local SPAN or RSPAN cannot be used for an ERSPAN session. Enter the ERSPAN mode after configuration.

↳ Source Port

- Global configuration mode. Mandatory.

- An SPAN direction can be selected during configuration of the SPAN source port. The direction is **both** by default; that is, both reception and transmission of packets are monitored.

↘ **Enabling an ERSPAN Session**

- Global configuration mode. Mandatory.
- By default, enabling an ERSPAN session is to enable ERSPAN mirroring. Only enabled ERSPAN sessions take effect.

↘ **Encapsulating the Origin IP Address**

- Global configuration mode. Mandatory.
- It is used to encapsulate origin IP addresses of SPAN packets.

↘ **Encapsulating the Destination IP Address**

- Global configuration mode. Mandatory.
- It is used to encapsulate destination IP addresses of SPAN packets.

↘ **Encapsulating IP TTL/DSCP**

- Global configuration mode. Optional.
- It is used to encapsulate DSCP values of SPAN IP packets.

↘ **vrf *vrf-name***

- Global configuration mode. Optional.
- It indicates the name of VRF. VRF must exist.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. You can also conduct packet capture analysis on the SPAN destination port and check whether SPAN takes effect according to the captured packets.

Related Commands

↘ **Configuring an ERSPAN Session**

↳ **Configuring VRF** *vrf-name*

Command	<code>vrf <i>vrf_name</i></code>
Parameter	<i>vrf_name</i> : Indicates the VRF name.
Description	
Command Mode	ERSPAN session mode
Usage Guide	-

Configuration Example

↳ The following uses a SPAN as an example.

<p>Configuration Steps</p>	<ul style="list-style-type: none"> As shown in Figure 1-2, on Switch A, create ERSPAN Session 1 and configure it as the source device, and configure Gi 0/1 as the source port.
	<pre>SwitchA(config)#monitor session 1 erspan-source SwitchA(config-mon-erspan-src)#source interface gigabitEthernet 0/1 both SwitchA(config-mon-erspan-src)#origin ip address 10.1.1.2 SwitchA(config-mon-erspan-src)#destination ip address 12.1.1.2 SwitchA(config-mon-erspan-src)#vrf vrf-name</pre>
<p>Verification</p>	<p>Step 1: Check the configuration of the device.</p>
	<pre>SwitchA#show running-config ! monitor session 1 erspan-src source interface GigabitEthernet 0/1 both origin ip address 10.1.1.2 destination ip address 12.1.1.2 vrf vrf-name</pre>
	<p>Step 2: Check the ERSPAN information of the device.</p> <pre>SwitchA#show monitor sess-num: 1 //ERSPAN Session span-type: ERSPAN_SOURCE //ERSPAN source device src-intf: //ERSPAN source port information GigabitEthernet 0/1 frame-type Both TX status: Inactive RX status: Inactive dest-intf: //ERSPAN output port information GigabitEthernet 0/2 origin ip address 10.1.1.2 destination ip address 12.1.1.2 ip ttl 64 ip dscp 0</pre>

```
vrf vrf-name
```

Common Errors

- The session ID used to configure ERSPAN mirroring is configured with RSPAN or LOCAL SPAN.
- Layer-3 routing interworking between source switch and destination switch fails.

6.5 Monitoring

Displaying

Description	Command
Displays all SPAN sessions in the system.	show monitor
Displays specific SPAN sessions.	show monitor session <i>session-id</i>

Debugging

 System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs SPAN.	debug span

7 Configuring sFlow

7.1 Overview

sFlow is a network monitoring technology jointly developed by InMon, HP, and FoundryNetworks in 2001. This technology has been standardized. It can provide complete traffic flows of Layer 2 to Layer 4, and it is applicable to traffic analysis in the extra-large network. This technology helps users analyze the performance, trend, and existence of network traffic flows in a detailed manner in real time.

sFlow has the following advantages:

- Accurate: sFlow supports accurate monitoring of traffic on a Gigabit network or a network with higher bandwidth.
- Scalable: One sFlow Collector can monitor thousands of sFlow Agents, and it has high scalability.
- Low cost: sFlow Agent is embedded in a network device, and its cost is low.

Protocol Specification

- sFlow Version 5
- RFC 1014

7.2 Applications

Typical Application	Scenario
Monitoring the LAN Traffic	Regard the device as an sFlow Agent, perform sampling of interface traffic in the LAN, and send the sFlow datagrams to an sFlow Collector for traffic analysis, thereby achieving the purpose of network monitoring.

7.2.1 Monitoring the LAN Traffic

Application Scenario

As shown in Figure 7-1, start switch A that serves as an sFlow Agent, enable flow sampling and counter sampling on port Te 0/1, monitor the traffic in the 192.168.1.0 network segment, encapsulate the sampling data into sFlow datagrams at regular intervals or when the buffer is full, and sent the sFlow data to the sFlow Collector for traffic analysis.

Figure 7-1

Function Deployment

- Configure the addresses of sFlow Agent and sFlow Collector on switch A.
- Enable flow sampling and counter sampling on port Te 0/1 of switch A.

i Lots of server software supports sFlow. You can obtain software supporting sFlow at <http://www.sflow.org/products/collectors.php>. The software sflowtrend is free of charge.

7.3 Features

Basic Concepts

↳ sFlow Agent

sFlow Agent is embedded in a network device. Generally, one network device can serve as an sFlow Agent. sFlow Agent can perform flow sampling and counter sampling, encapsulate sampled data into sFlow datagrams, and send the sFlow datagrams to the sFlow Collector.

sFlow datagrams are encapsulated in UDP. Figure 7-2 shows the sFlow datagram format.

Figure 7-2 sFlow Datagram Format

One sFlow datagram may contain one or multiple flow samples and counter samples.

Figure 7-3 sFlow Header

sFlow Geader Description:

Field	Description
sFlow version	sFlow version. V2, V4, and V5 are available. Currently, Nodexon supports V5 only.
IP version of the agent/switch	IP address version of the sFlow Agent
Agent IP address	IP address of the sFlow Agent
Sub agent id	Sub-agent ID
Datagram sequence number	Serial number of the sFlow datagram
Switch uptime	Duration from the startup time of the switch to the current time
n samples in datagram	The number of samples in the an sFlow datagram. One sFlow datagram may contain one or multiple flow samples and counter samples.

➤ sFlow Collector

sFlow Collector receives and analyzes the sFlow datagram sent from the sFlow Agent. sFlow Collector may be a PC or server. A PC or server installed with the application software for sFlow datagram analysis can be regarded as an sFlow Collector.

➤ Flow Sampling

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet.

Figure 7-4 Flow Sample Header

1	8	32
int data format sample data (20 bit enterprise & 12 bit format) (standard enterprise 0, formats 1)		
int sample length byte		
int sample sequence number		
int source id type (0=ifIndex) 1=smonVlanDataSource 2=entPhysicalEntry	int source id index value	
int sampling rate		
int sample pool (total number of packets that could have been sampled)		
int drops (packets dropped due to a lack of resources)		
int input (SNMP ifIndex of input interface, 0 if not known)		
int output (SNMP ifIndex of output interface, 0 if not known) broadcast or multicast are handled as follows: the first bit indicates multiple destinations, the lower order bits number of interfaces		
int n * flow records		

↘ Counter Sampling

In counter sampling, an sFlow Agent periodically obtains the statistics and CPU usage on a specified interface. The statistics on the interface include the number of packets input through the interface and the number of packets output through the interface.

Figure 7-5 Counter Sample Header

Functions and Features

Feature	Description
Flow Sampling	Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.
Counter Sampling	Periodically send the statistics on the interface to the sFlow Collector for analysis.

7.3.1 Flow Sampling

Sample the traffic flowing through the interface, and send the encapsulated sFlow datagram to the sFlow Collector for analysis.

Working Principle

Based on the specified sampling rate, the sFlow Agent device performs flow sampling on the traffic flowing through an interface, including copying the header of the packet, extracting the Ethernet header and IP header of the packet, and obtaining the route information of the packet. Then, the sFlow Agent encapsulates the flow sampling data into an sFlow datagram and sends the datagram to the sFlow Collector for analysis.

7.3.2 Counter Sampling

Periodically send the statistics on the interface to the sFlow Collector for analysis.

Working Principle

The sFlow Agent performs interface polling on a regular basis. For an interface whose counter sampling interval expires, the sFlow Agent obtains the statistics on this interface, encapsulates the statistics into an sFlow datagram, and sends the datagram to the sFlow Collector for analysis.

7.4 Configuration

Configuration Item	Suggestion & Related Command	
Configuring Basic Functions of sFlow	 Mandatory configuration. Establish communication connections between sFlow Agent and sFlow Collector.	
	sflow agent {address interface}	Configures the sFlow Agent address.
	sflow collector collector-id destination	Configures the sFlow Collector address.
	 Mandatory configuration. Enable flow sampling and counter sampling.	
	sflow counter collector	Enables the sFlow Agent to send counter samples to the sFlow Collector.
	sflow flow collector	Enables the sFlow Agent to send flow samples to the sFlow Collector .
	sflow enable	Enables sFlow sampling for the configuration interface, that is, enables counter sampling and flow sampling.
Configuring Optional Parameters of sFlow	 Optional configuration. Sets the optional parameter attributes of sFlow.	
	sflow collector collector-id max-datagram-size	Configures the maximum length of the sFlow datagram.
	sflow counter interval	Configures the counter sampling interval.
	sflow flow max-header	Configures the maximum length of the packet header copied during flow sampling.
	sflow sampling-rate	Configures the sampling rate of flow sampling.

7.4.1 Configuring Basic Functions of sFlow

Configuration Effect

- sFlow Agent and sFlow Collector can communicate with each other.
- Traffic flowing through the interface are sampled based on the default sampling rate and sent to the sFlow Collector for analysis.
- Statistics of the interface are periodically sent to the sFlow Collector based on the default sampling interval for analysis.

Notes

- Flow sampling can be configured on only physical interfaces.
- To enable the sFlow Collector to analyze the flow sampling results, the IP address of the sFlow Collector on the sFlow Agent device is required.

Configuration Steps

↳ **Configuring sFlow Agent Address**

- Mandatory configuration.
- Use the **sflow agent address** command to configure the address of the sFlow Agent.
- The sFlow Agent address must be a valid address. That is, the sFlow Agent address must not be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.

Command	sflow agent { address { ip-address ipv6 ipv6-address } } { interface { interface-name ipv6 interface-name } }
Parameter Description	<p>address: Configures the IP address of the sFlow agent.</p> <p><i>ip-address:</i> sFlow Agent IPv4 address</p> <p>ipv6 ipv6-address: sFlow Agent IPv6 address</p> <p>interface: Configures the interface of the sFlow agent.</p> <p><i>interface-name:</i> Interface of IPv4 address.</p> <p>ipv6 interface-name: Interface of IPv6 address.</p>
Defaults	No sFlow Agent address is configured by default
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the Agent IP address field in the output sFlow datagram. The datagram not configured with this field cannot be output. The sFlow Agent address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Agent address, a message indicating configuration failure is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

↳ **Configuring sFlow Collector Address**

- Mandatory configuration.
- Use the **sflow collector** command to configure the address of the sFlow Collector.
- The sFlow Collector address must be a valid address. That is, the sFlow Collector address must not be a multicast or broadcast address. sFlow Collector must exist, and the route to it must be reachable.

Command	sflow collector collector-id destination { ip-address ipv6 ipv6_address } udp-port [[vrf vrf-name] [oob]]
Parameter	<i>collector-id:</i> sFlow Collector ID. The range is from 1 to 2.

Description	<p><i>ip-address</i>: sFlow Agent IPv4 address. It is not configured by default</p> <p>ipv6 <i>ipv6-address</i>: sFlow Agent IPv6 address. It is not configured by default</p> <p><i>udp-port</i>: sFlow Collector listening port number</p> <p>vrf <i>vrf-name</i>: VRF instance name. It is not configured by default</p> <p>oob: The sampled traffics are output through the management interface. By default, this parameter is not configured.</p>
Command Mode	Global configuration mode
Configuration Usage	<p>This command is used to configure the sFlow Collector address. The sFlow Collector address shall be a host address. When a non-host address (for example, a multicast or broadcast address) is configured as the sFlow Collector address, a message indicating configuration failure is displayed. The sFlow Collector monitors the sFlow datagram on the specified port. When the vrf parameter is configured, the corresponding VRF instance must exist. When you remove the a VRF instance, the sFlow Collector address will be removed if this VRF instance is also configured for an sFlow Collector address. When the oob parameter is configured, a datagram is sent to the sFlow Collector through the management interface.</p>

➤ **Enabling sFlow Samples Output to the sFlow Collector**

- Mandatory configuration.
- You can use the **sflow flow collector** command to enable the sFlow Agent to send flow samples to the sFlow Collector.
- This function must be enabled on the interface to send flow samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command	sflow flow collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending the flow samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	<p>This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.</p>

➤ **Enabling Counter Samples Output to the sFlow Collector**

- Mandatory configuration.
- You can use the **sflow counter collector** command to enable the sFlow Agent to send counter samples to the sFlow Collector.

- This must be enabled on the interface to send counter samples to the sFlow Collector. In addition, sFlow Collector must exist, the route to it must be reachable, and the IP address of the corresponding sFlow Collector has been configured on the sFlow Agent device.

Command	sflow counter collector <i>collector-id</i>
Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2.
Defaults	Sending counter samples to the sFlow Collector is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used for physical ports, SVI ports and sub routed ports and aggregate ports. sFlow datagrams can be output only when an IP address is configured for the corresponding sFlow Collector.

▾ Enabling Counter Sampling and Flow Sampling

- Mandatory configuration.
- You can use the **sflow enable** command to enable the flow sampling and counter sampling on an interface.
- The forwarding performance of an interface may be affected after flow sampling is enabled.

Command	sflow enable
Parameter Description	
Defaults	The sFlow sampling function on an interface is disabled by default.
Command Mode	Interface configuration mode
Configuration Usage	This command can be used to enable counter sampling and flow sampling for physical ports and aggregate ports.

Verification

- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

▾ Configuring Flow Sampling and Counter Sampling for sFlow Agent

2	NULL	0	1400	
Port information				
Interface		CID	FID	Enable
TenGigabitEthernet 0/1		1	1	Y

Information displayed on the sFlowTrend software:

The preceding figure shows the Top N page of the sFlowTrend software. This page displays the flow sampling results and displays the top 5 source IP addresses that involve the largest traffic. The total incoming traffic is about 450 Kpps and the total outgoing traffic is 450 Kpps, which are consistent with the actual traffic.

7.4.2 Configuring Optional Parameters of sFlow

Configuration Effect

You can adjust the data sampling accuracy by modifying relevant parameter attributes of sFlow.

Notes

- The forwarding performance may be affected when the sampling rate is too low.

Configuration Steps

Configuring the Maximum Length of the Output sFlow Datagram

- Optional configuration.
- You can use the **sflow collector** command to configure the length of the sFlow datagram, excluding the Ethernet header, IP header, and UDP header. An sFlow datagram may contain one or multiple flow samples and counter samples. Configuration of the output sFlow datagram's maximum length may lead to the result that the number of sFlow datagrams output during processing of a certain number of flow samples differs from the number of sFlow datagrams output during processing of the same number of counter packets. If the maximum length is greater than MTU, the output sFlow datagrams will be segmented.

Command	sflow collector <i>collector-id</i> max-datagram-size <i>datagram-size</i>
----------------	--

Parameter Description	<i>collector-id</i> : sFlow Collector ID. The range is from 1 to 2 max-datagram-size <i>datagram-size</i> : maximum length of the output sFlow datagram. The range is from 200 to 9,000.
Defaults	The default value is 1,400.
Command Mode	Global configuration mode
Configuration Usage	-

▾ Configuring the Flow Sampling Rate

- Optional configuration.
- You can use the **sflow sampling-rate** command to configure the global flow sampling rate.
- Configuration of flow sampling rate may affect the sFlow sampling accuracy. A lower sampling rate means a higher accuracy and larger CPU consumption. Therefore, the forwarding performance of the interface may be affected when the sampling rate is low.

Command	sflow sampling-rate <i>rate</i>
Parameter Description	<i>rate</i> : Sampling rate of sFlow sampling. One packet is sampled from every <i>n</i> packets (<i>n</i> equals the value of rate). The range is from 4,096 to 16,777,215.
Defaults	The default global flow sampling rate is 8,192.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sampling rate of sFlow flow sampling, and sFlow flow sampling of all interfaces uses this sampling rate.

▾ Configuring the Maximum Length of the Packet Header Copied During Flow Sampling

- Optional configuration.
- You can use the **sflow flow max-header** command to configure the length of the packet header copied during flow sampling globally.
- Users can use this command to modify the datagram information to be sent to the sFlow Collector. For example, if a user concerns about the IP header, this user can configure the length to 56 bytes. During encapsulation of flow samples, the first 56 bytes of the sample packet are copied to the sFlow datagram.

Command	sflow flow max-header <i>length</i>
Parameter Description	<i>length</i> : maximum length of the packet header to be copied. The range is from 18 to 256.
Defaults	The default length of the packet header to be copied during global flow sampling is 64 bytes.
Command Mode	Global configuration mode
Configuration Usage	Configure the maximum number of bytes of the packet content copied from the header of the original packet. The copied content is recorded in the generated sample.

▾ **Configuring the Sampling Interval**

- Optional configuration.
- You can use the **sflow counter interval** command to configure the global counter sampling interval.
- Enable the counter sampling interface to send the statistics on it to the sFlow Collector at the sampling interval.

Command	sflow counter interval seconds
Parameter	<i>seconds</i> : time interval. The range is form 3 to 2,147,483,647. The unit is second.
Description	
Defaults	The default global counter sampling interval is 30 seconds.
Command Mode	Global configuration mode
Configuration Usage	This command is used to configure the global sFlow counter sampling interval, and sFlow Counter sampling of all interfaces uses this sampling interval.

Verification

- Check whether an sFlow datagram with the flow samples is received on the sFlow Collector.
- Use the **show sflow** command to display the sFlow configuration, and check whether the displayed information is consistent with the configuration.

Configuration Examples

▾ **Configuring Optional Parameters of sFlow**

Scenario	See Figure 7-6.
	<ul style="list-style-type: none"> ● Set the flow sampling rate to 4,096 in global configuration mode. ● Configure the length of the packet header copied during flow sampling to 128 bytes in global configuration mode. ● Set the sampling interval to 10 in global configuration mode.
Configuration Steps	<pre>Nodexon# configure terminal Nodexon(config)# sflow sampling-rate 4096 Nodexon(config)# sflow flow max-header 128 Nodexon(config)# sflow counter interval 10</pre>
	<p>Make traffic pass through interface TenGigabitEthernet 0/1.</p> <ul style="list-style-type: none"> ● Check whether there is traffic on interface TenGigabitEthernet 0/1 on sFlow Collector 1. ● Use the show sflow command to check whether the command output is consistent with the configuration.

Verification	
	<pre> Nodexon# show sflow sFlow datagram version 5 Global information: Agent IP: 10.10.10.10 sflow counter interval:10 sflow flow max-header:128 sflow sampling-rate:4096 Collector information: ID IP Port Size VPN 1 192.168.2.100 6343 1400 2 NULL 0 1400 Port information Interface CID FID Enable TenGigabitEthernet 0/1 0 1 Y </pre>

Displaying

Function	Command
Displays the sFlow configuration.	show sflow

Specifications and Limitations

This section lists the specifications and limitations of features supported on NX-3800 series products.

Feature	Description
MAC Address	<ol style="list-style-type: none"> The NX-3800 series do not learn but forward packets whose source MAC addresses and destination MAC addresses are all 0's. The NX-3800 series require the capacity of two addresses to filter an address. For example, if 4,000 MAC addresses need to be filtered globally, the available address capacity of the NX-3800 series reduces by 8,000.
QinQ	<ol style="list-style-type: none"> The NX-3800 series support four global tag protocol identifier (TPID) values. One of the TPID values must be 0x8100, and the other three are arbitrary.
Private VLAN	The NX-3800 series do not support the isolation trunk port and the hybrid trunk port.
MMU	By default, the buffer mode is normal.
SPAN	<ol style="list-style-type: none"> On the NX-3800 series, the Tx mirroring source port can mirror packets sent from the CPU.
ERSPAN	<ol style="list-style-type: none"> The NX-3800 series support ERSPAN.
sFlow	<ol style="list-style-type: none"> The NX-3800 series support the sFlow statistics function. The sFlow sampling rate of the NX-3800 series ranges from 4,096 to 65,535. The sFlow sampling rate is implemented by setting the sampling threshold register of the chip. The value of the sampling threshold register is the rounded value of the maximum sampling base (0xffff) dividing the sFlow sampling rate. The sampling rate is accurate only if the remainder is an integer. Therefore, a larger sampling ratio indicates a larger error. Within the sampling rate range, any sampling ratio error of the NX-3800 series cannot exceed 10%.
QoS	<ol style="list-style-type: none"> The NX-3800 series do not support configuration of the QoS trust mode on the SVI. Members in a logical port group must be in the same line card. Members to be added to a logical port group must be physical ports or aggregate ports. The deny entry in an ACL matching a class-map does not take effect. The NX-3800 series do not support VID modification. When QoS is applied to the outbound direction, the NX-3800 series alter the DSCP value of packets whose bandwidth exceeds the limit but keeps the CoS value unchanged. When QoS is applied to the inbound direction, the NX-3800 series alter the DSCP value and CoS value of packets whose bandwidth exceeds the limit. The NX-3800 series alter the CoS value of packets whose bandwidth exceeds the limit, and modify the DSCP value synchronously. After the none-tos option is set, the NX-3800 series do not modify the DSCP value when altering the CoS value. When the DSCP value of packets matches a QoS policy, the NX-3800 series neither alter the CoS value nor modify the DSCP value of MPLS packets. The NX-3800 series do not support the none-tos option when CoS is configured. On the NX-3800 series, bandwidth limit refers to the actual bandwidth, including the load of the preamble and interframe gap. The preamble and interframe gap carried in each packet occupy

- bytes.
10. The NX-3800 series support the minimum rate limit granularity of 8 kbit/s. The rate limit granularities vary with the rate limit settings. The following table describes the relationship between rate limit values and granularities.

Rate Limit Range	64 kbps–2 Gbps	2 Gbps–4 Gbps	4 Gbps–8 Gbps
Granularity	8 kbps	16 kbps	32 kbps
Rate Limit Range	8 Gbps–16 Gbps	16 Gbps–32 Gbps	32 Gbps–40 Gbps
Granularity	64 kbps	128 kbps	256 kbps

11. For the second parameter (burst traffic) in the QoS rate-limit policy, if the parameter value is small, the actual rate may be excessively small upon burst traffic. If the parameter value is large, the actual rate may be excessively large. Users can use the following recommended configurations based on actual situation:
- (1) If the configured rate limit is less than 1,024 kbps, the recommended burst-size value is 1,024 KBytes.
 - (2) If the configured rate limit is 10,240 kbps, it is recommended to set the burst-size value to be same as the rate limit or use the maximum value (the allowable burst-size value of products may be less than 10,240 KBytes).
 - (3) If the configured rate limit is greater than 10,240 kbps, it is recommended to set the burst-size value to the allowable maximum value of the device.
12. For the second parameter in the QoS rate-limit policy, when the rate limit is large, the second parameter needs to be adjusted. Otherwise, the rate limit may be inaccurate. Users can use the following recommended configuration:
- For 10G or 40G ports, it is recommended to set the burst-size value to 32 or a larger value.
13. The NX-3800 series support the application of a policy-map to the outbound direction. When a policy is applied to an aggregate port of the NX-3800 series, member ports of the aggregate port must meet the following conditions and the bandwidth limit is the bandwidth shared by all member ports of the aggregate port:
- For NX-3875-48G4X member ports of the aggregate port must be the front or rear 24 ports of the line card.
14. On the NX-3800 series, a class-map needs to be associated with an ACL, and therefore all restrictions configured in an ACL are still available after the ACL QoS function is enabled. For details, see Configuring ACL chapter.
15. Policy-maps cannot be applied to SVIs.
16. Policy-maps can be configured in the output direction but cannot be configured on APs.
17. Policy-maps configured in the output direction do not support re-marking the CoS value of packets. The CoS value of packets is not re-marked when the DSCP value of packets is re-marked.

- 18. Logical port groups do not support QoS policies in the output direction.
- 19. The virtual switching link (VSL) port of the NX-3800 series adopts the strict priority (SP) + deficit round robin (DRR) scheduling algorithm by default. Queue 7 adopts the SP scheduling and the weights of other queues are all 1, which cannot be modified by users.
- 20. The NX-3800 series support mapping configuration on physical ports.
- 21. Administrators can configure the DSCP-CoS and CoS-threshold mapping to implement the DSCP-threshold mapping.
- 22. Administrators can configure the CoS-threshold and CoS-queue mapping to implement the queue-threshold mapping.
- 23. The default priority of management packets is 7 in virtual switching unit (VSU) mode and the packets are placed in Queue 8. It is not recommended to change this mapping.
- 24. Only the **show run** command can be used to check whether the WRED function is enabled globally.
- 25. The lower threshold and maximum drop probability of a queue form a group of WRED configurations. The NX-3800 series support a maximum of 120 groups of WRED configurations. It is recommended that the configured number of WRED configuration groups not exceed 120. The extra WRED configuration groups may result in improper running.
- 26. If the lower threshold value is 100%, the WRED function is disabled.

CPU Protection

Default values of CPU Protect of the NX-3800 series:

ACL	<ol style="list-style-type: none"> 1. On the NX-3800 series, the ACL applied to the inbound direction does not support the Layer-4 port "NEQ" matching for TCP and UDP packets, and the ACL applied in the outbound direction supports only the Layer-4 port "EQ" matching for TCP and UDP packets. 2. On the NX-3800 series, IPv6 ACLs support matching by the following fields: Protocol, sip, l4_src, dip, l4_dst, dscp, and flow_label. An IPv6 ACL supports matching only based on the following two field groups: <ol style="list-style-type: none"> 1) Protocol, sip, l4_src, l4_dst, dscp, flow_label, range 2) Protocol, dip, l4_src, l4_dst, dscp, flow_label, range 3) An ACL cannot use all the fields for matching. In addition, IPv6 ACLs do not support matching by fragment matching and do not support matching by flow_label in the outbound direction. 4) When high-order 64 bits (the mask length is smaller than or equal to 64) need to be matched for the source IP address and destination IP address, matching based on the IPv6 5-tuple is supported. 3. On the NX-3800 series, security ACLs applied to an SVI are effective to both intra-VLAN packets forwarded by bridges and inter-VLAN routed packets. As a result, users in the VLAN cannot perform communication. 4. The NX-3800 series cannot identify the fragment flag field in the IPv6 packets. If an IPv6 ACL contains the fragment flag, the fragment flag is ignored in packet matching. This is equivalent to absence of the fragment flag in ACLs, and matching is performed on all packets, including the first-fragment packets and non-first-fragment packets. 5. The NX-3800 series support the switching between fragment packet matching modes only in IP
-----	---

	<p>extended ACLs and expert extended ACLs.</p> <p>6. On the NX-3800 series, ACL80 supports only the following common fields: destination MAC address, source MAC address, VID, ETYPE, IP protocol number, source IPv4 address, destination IPv4 address, destination port ID, source port ID, ICMP type, and ICMP code.</p>
DoS	<p>1. The NX-3800 series consider the following types of TCP packets invalid:</p> <ul style="list-style-type: none"> (1) TCP packets with both the SYN flag and FIN flag set (2) TCP packets without any flag (3) TCP packets with the FIN flag set but the ACK flag not set (4) TCP packets with the SYN flag set and the source port ID ranging from 0 to 1,023 <p>2. When the function of defending against invalid TCP packet attacks is enabled, the NX-3800 series can filter out all of the Type 1 and Type 4 invalid TCP packets, the Type 2 invalid TCP packets without any flag and the sequence number being 0, and the Type 3 invalid TCP packets with the FIN flag, URG flag, and PSH flag set and the sequence number being 0.</p> <p>Due to chip limitation, the preceding types of TCP packets cannot be filtered during use of DoS.</p>
Intelligent Monitoring	<p>1. The S5750C-28GT4XS-H/S5750C-28SFP4XS-H/S5750C-48GT4XS-H products provide monitoring and alarm reporting based on two temperatures, that is, the air inlet temperature and the switching chip MAC node temperature. The alarm policies are as follows:</p> <ul style="list-style-type: none"> a. If the air inlet temperature is greater than 55°C or the MAC node temperature is greater than 91°C, the Status indicator is on in yellow and a minor temperature alarm is reported. b. If the air inlet temperature is greater than 60°C or the MAC node temperature is greater than 96°C, the Status indicator is on in red and a major temperature alarm is reported. c. If the air inlet temperature is greater than 70°C or the MAC node temperature is greater than 102°C in three consecutive times, the device restarts. <p>2. The NX-3875-48S4X/NX-3875-48G4XH products provide monitoring and alarm reporting based on two temperatures, that is, the air inlet temperature and the switching chip MAC node temperature. The alarm policies are as follows:</p> <ul style="list-style-type: none"> a. If the air inlet temperature is greater than 58°C or the MAC node temperature is greater than 91°C, the Status indicator is on in yellow and a minor temperature alarm is reported. b. If the air inlet temperature is greater than 63°C or the MAC node temperature is greater than 96°C, the Status indicator is on in red and a major temperature alarm is reported. c. If the air inlet temperature is greater than 71°C or the MAC node temperature is greater than 102°C in three consecutive times, the device restarts. <p>3. The MCU displays information about the power supply power, card power, and total power message. The power supply serial numbers of the NX-3800 series are 1 and 2.</p> <p>4. The NX-3800 series support fan speed adjustment at three levels: 0 (stop), 1 (low-speed), and 2 (high-speed).</p> <p>5. The NX-3800 series do not support hot swapping of the fan modules. If more than one fan is faulty, the indicator on the panel will be on in red.</p>
PoE	<p>Only NX-3875-48G4XH products support the PoE function.</p>
VSU	<p>1. At least one 10G port must be specified as a member port of a VSL for each device.</p>

	<ol style="list-style-type: none"> 2. VSL member ports of two devices are connected via the SFP+ module and fiber cables, or copper cables. 3. The NX-3800 series support using M5000H-01QXS expansion modules to form a VSU. If the device is a VSU module, ports of the expansion module will be served as VSL ports by default. Manual configuration is not required or allowed. 4. 1000M ports cannot be used as VSL ports. 5. VSL APs and VSP AP auto-negotiation do not need to be configured when VSL ports are configured. 6. VSL heartbeat detection cannot be configured on the NX-3800 series. <table border="1" data-bbox="341 567 1477 735"> <thead> <tr> <th>Product Name</th> <th>Stack Module</th> <th>Common Port</th> <th>Linear Topology</th> <th>Ring Topology</th> <th>Maximum Number of Member Devices</th> </tr> </thead> <tbody> <tr> <td>NX-3800 series</td> <td>Supported</td> <td>Supported</td> <td>Supported</td> <td>Supported</td> <td>16</td> </tr> </tbody> </table> <ol style="list-style-type: none"> 7. On the NX-3800 series, only a single BFD detection line needs to be configured, to prevent user connection errors possibly occurring when multiple BFD detections lines are configured for BFD port detection. 8. When an aggregate port is used for DAD, the uplink device must be provided by Nodexon and support DAD packet forwarding. Currently, the NX-3800 series support packet forwarding. 	Product Name	Stack Module	Common Port	Linear Topology	Ring Topology	Maximum Number of Member Devices	NX-3800 series	Supported	Supported	Supported	Supported	16

NX-3800 series	Supported	Supported	Supported	Supported	16								
NTP	Nodexon products of the current version support authentication keys with a maximum of 1,024 bits. A unique key can be set for each server for secure communication.												
PBR	<p>On the NX-3800 series:</p> <ul style="list-style-type: none"> ● If an inexistent ACL is used for policy-based routing (PBR), all packets are matched and forwarded in common routing mode. If an ACL without any ACE is used for PBR, packet matching starts from the next ACL. The deny option of an ACE indicates to perform common forwarding. For example, deny any any indicates forwarding in common routing mode. ● The PBR takes effect to packets destined for the local host. If PBR is undesired for IPv4/IPv6 packets destined for the local host, manually add "deny local IPv4/IPv6 address" as the first ACE of the IPv4/IPv6 ACL. 												
uRPF	When the uRPF function is enabled, the routing table capacity is halved. Therefore, if the uRPF function is enabled when the size of routing table entries exceeds half of the total routing table capacity, routing table entries may be lost.												
UFT	The NX-3800 series support only four UFT modes, including default, gateway-max, route-v4max, and route-v6max.
